"Electrical Testing for Telegraph Engineers."—By J. Elton Young, M.I.E.E. The scope of the book aims at furnishing a fuller treatment of the subject, from the standpoint of the Telegraph Engineer, than it has hitherto received, whilst it endeavours to facilitate a thorough comprehension of the theory of testing as applied to electrical lines in general. The Author hopes that, besides Telegraph and Telephone Engineers, it may, perhaps, also prove of service to those in charge of cables for the transmission of light and power. The localisation of faults has been very fully investigated, including the different degrees in which the various methods are affected by the presence of a second fault or of general leakage.—*Extract from Preface.* Demy 8vo, fully illustrated. 10s. 6d., post free; abroad 11s.

"Submarine Cable-Laying and Repairing."—By H. D. Wilkinson, M.I.E.E., &c., fully illustrated; price 12s. 6d.

"The Students' Guide to Submarine Cable Testing."—A new work by Messrs. H. K. C. Fisher and J. C. H. Darby, with the above title, is now ready, price 6s. net; abroad, 6s. 3d. This work is intended to serve as a guide to operators already in the telegraph service, and to those who desire to enter that service. The great cable companies now insist that their operators and probationers shall pass certain examinations in electrical subjects. The book is very fully illustrated. *Second Edition now ready.*

"Practical Notes for Electrical Students."—By Messrs. A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free.

"Electro-Chemistry."—By Dr. G. Gore. Third Edition. Price 2s., post free.

"Electric Motive Power," by Albion T. Snell, contains the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 260 illustrations. Price 10s. 6d., post free; abroad, 11s.

"Wireless Telegraphy: Signalling across Space without Wires by Electric Waves."—By Dr. O. J. Lodge, with many original illustrations. *Enlarged Edition*, 2s. 6d. net, 2s. 9d. post free.

"Laboratory Notes and Forms."—With the above title we have ready the New Edition of a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators and Students. The object of this series is the saving of the time of the Teacher and his Assistants, and to serve as a record of the work done by the Student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen net; in sets of any three, 1s. net; or the set of Twenty (Elementary or Advanced) Exercises can be obtained, price 5s. 6d. net. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. net; or in handy portfolio, price 12s. net; or bound in strong cloth case, price 12s. 6d. net. Strong portfolios can be had, price 1s. each.

NOW READY.—The cheaper edition of Dr. J. A. Fleming's "Electrical Laboratory Notes and Forms." These cheaper Forms have been prepared for the use of students and teachers at the Polytechnic and other science classes throughout the country. The demand for the original set of these Notes and Forms has led to a request for a cheaper set for use at the day and evening classes at many of the technical institutes. These new Forms, which differ only from the higher-priced set in being printed on smaller and cheaper paper and with less space for tabulated records, are issued at half the price of the original set.

"The Incandescent Lamp and its Manufacture."—This book, written by Mr. Gilbert S. Ram, is now ready. Price 7s. 6d.; abroad, 8s.

"The Steam Engine Indicator and Indicator Diagrams."—Edited and enlarged by W. Worby Beaumont. Price 3s. 6d., post free.

"The Art of Electrolytic Separation of Metals."—A second issue of Dr. Gore's book is now ready, price 10s. 6d., post free.

"The Manufacture of Electric Light Carbons."—A Practical Guide to the establishment of a Carbon Manufactory. Fully illustrated. price 1s. 6d.; post free, 1s. 9d.

"The Bibliography of X-Ray Literature and Research, 1896-97." A valuable, up-to-date compilation. Being an attempt to classify the data relating to X-Ray work. This work contains a quantity of general as well as special information bearing upon the whole subject of electrical discharge research. Price 5s., post free; abroad, 5s. 3d.

"Localisation of Faults in Electric Light Mains."—By F. C. Raphael. Price 5s., post free; abroad, 5s. 6d. Prospectus on application.

"Electrical Engineering Formulæ," a pocket-book, by Messrs. W. Geipel and H. M. Kilgour; price 7s. 6d.; by post, 7s. 9d.; abroad, 8s. A fine large paper edition with wide margins for notes can also be supplied. Price 12s. 6d.; post free, 13s.; abroad, 13s. 6d. *New Edition in the press.*

"The Alternate Current Transformer," Vol. I.—By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. *New Edition.* Price 12s. 6d., post free. Vol. II., price 12s. 6d. post free, is also ready.

"Electromagnetic Theory."—By Oliver Heaviside. Vol. I., price 12s. 6d.; post free, 13s.

"Electric Lamps and Electric Lighting," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free.

"The Electrician" Primers.—In Two Volumes. Vol. I., Theory. Vol. II., Practice. Price, stout paper cover, 2s. 2d. each, post free; cloth 2s. 9d. Single Primers, 3d. each, post free.

"Armature Windings of Electric Machines."—By H. F. Parshall and H. M. Hobart. This work has been compiled from notes made by Mr. Parshall in his capacity as Chief Designing Engineer of the Edison and General Electric Companies of America, and is intended to serve as a working treatise on dynamo design. Large 4to, 370 pages, 140 full-page illustrations and 65 full-page tables, 30s., post free.

"Drum Armatures and Commutators," by Mr. F. Marten Weymouth, also ready. Price 7s. 6d.; abroad, 8s. Prospectus on application.

"The Electrician" Electrical Trades' Directory and Handbook.—An important announcement in connection with the 1899 issue of the "Big Blue Book" will be found in an advertisement on another page of the present issue, to which our readers will please refer.

TENDERS INVITED.

The Corporation of *Barnsley* invite tenders for the supply and erection of: (1) Lancashire boilers and Green's economiser; (2) engines, dynamos, switchboard, condensers, feed-water pumps, balancing transformers, boosters, piping, tanks, crane, wiring of works, and engine, &c., foundations; (3) secondary batteries and accessories; (4) feeder and distributing mains (solid system); (5) potential leads, network and service boxes and service connections. Further particulars in our advertisement columns, and specifications, &c., can be obtained on application to the consulting engineer (Mr. Thos. L. Miller), 7, Tower-buildings, N., Water-street, Liverpool. The Corporation also invite tenders for the erection of a chimney and engine, dynamo and boiler house, storage rooms and offices. Specification, &c., from Mr. J. Henry Taylor, borough surveyor, to whom tenders should be sent by noon of Monday, Dec. 12th.

As will be seen from an advertisement, the Corporation of *Sunderland* require tenders for the supply of three 125 kilowatt, direct current, high speed, steam dynamos. Specifications, &c., may be obtained from the borough electrical engineer (Mr. J. F. C. Snell), Dunning-street, Sunderland. Tenders, addressed to chairman of Lighting committee, Town Hall, Sunderland, to the office of the town clerk (Mr. Fras. M. Bowey), by noon of Friday, 30th inst.

The *Leeds* City Council require tenders for the supply of underground conductors, switchboards, &c., in connection with the extension of their electric tramways. Additional particulars are given in an advertisement elsewhere. Plans and specifications may be obtained from the city engineer, Municipal Buildings, Leeds, or from Messrs. Hopkinson and Talbot, 26, Victoria-street, Westminster, S.W. Tenders, addressed to the town clerk, must be in by 10 a.m. of the 29th inst.

The Commissioners of the Burgh of *Stirling* invite tenders for the following:—(1) Lancashire boilers, with mechanical stokers; (2) engines, dynamos, pumps, steam pipes, &c., Green's economiser and tools; (3) storage batteries; (4) switchboard and boosters; and (5) arc lamps. Further particulars are set out in our advertisement columns, and copies of specification, &c., can be obtained from the clerk to the Commissioners (Mr. Thomas L. Galbraith), Town Clerk's Office, Stirling. Specifications and drawings may be seen at, but not obtained from, the office of Prof. Alex. B. W. Kennedy, 17, Victoria-street, S.W. Tenders to the Town Clerk's Office by Jan. 2 next.

Extension of Time.—The *Salford* Electric Lighting committee invite tenders for the supply and erection of the following: (1) boilers, (2) engines, (3) dynamos, (4) boiler feed-pumps, (5) mechanical stokers, (6) superheaters, (7) economisers, (8) condensers, &c., (9) steam and water pipes, (10) cranes and weighing machines, (11) tanks, &c., (12) switchboards, and (13) booster. Tenders to Town Hall, Salford, *by Dec. 15.*

The *Shanghai* Council invite tenders for a concession, for a period of thirty years, for the exclusive right of establishing and working a telephone system in Shanghai. Further particulars are set out in an advertisement on another page, and plans may be seen and particulars obtained on application to Messrs. John Pook and Co., 8, Jeffrey's-square, St. Mary Axe, London, E.C. Further information may be obtained on application to Mr. Charles Mayne, municipal engineer, Shanghai, whose telegraphic address is

Digitized by Google

"Dynamo Shanghai." Tenders must be sent to the secretary (Mr. J. O. P. Bland), Shanghai, by noon of Friday, March 31.

The *Shanghai* Council also invite tenders for a concession for constructing and working about 23 miles of electric tramways on the trolley system. Particulars from Messrs. John Pook and Co., 8, Jeffrey's-square, London, E.C. Tenders to Mr. J. O. P. Bland, secretary, by noon of Wednesday, March 15, 1899.

The *Beckenham* District Council invite tenders for the supply of electric lighting plant. (For particulars see our issue of Dec. 2.) Tenders to Mr. F. Stevens by noon of Dec. 17.

The *Shoreditch* (London) Vestry invite tenders for the supply of six direct-current rotary transformers, with switch gear complete, three of 66 kilowatt and three of 33 kilowatt capacity. Tenders by noon, Dec. 13, to Mr. C. Newton Russell, Coronet-street, Shoreditch.

Particulars can be obtained at the Commercial Department of the Foreign Office of the tenders which are invited by the *Egyptian* State Administration of Lighthouses for the supply of two steam boilers. Tenders have to be in to the Controller General, Alexandria, by noon of the 31st inst.

TENDERS RECEIVED AND ACCEPTED.

The following tenders have been received by the *Southampton* Corporation for the supply of two engines and dynamos (each equal to an output of 24,000 watts), with accessories, for the electric lighting of Knowle County Asylum :—

F. Shalders (*accepted*)..	£4,300	0	0	Ernest Scott and Mountain	£4,865	0 0
Sax, Slatter and Co....	9,500	0	0	Bow, McLachlin & Co.	4,700	0 0
Prestwich and Burt ...	5,804	2	6	Joel and Potter	4,700	0 0
Thomas and Taylor ...	5,700	0	0	Calvert and Co.....	4,650	0 0
Crompton and Co.....	5,650	0	0	Brush Co.	4,630	0 0
Heath, Snoxell and Co.	5,540	0	0	Scott Anderson & Beit	3,856	10 0
Matthews and Yates...	5,385	0	0	Frank Suter and Co....	3,351	10 0
Laing, Wharton & Down	4,998	0	0			

The *Liverpool* Corporation have accepted the tender of the British Thomson-Houston Co. for the supply of 12 motor cars complete for the tramways department, at £6,752. The tender of Messrs. Robert W. Blackwell and Co. has also been accepted for the overhead equipment of the Aigburth-road electric line at £1,780. 12s. 1d.

APPOINTMENTS VACANT AND FILLED.

The Electricity Supply committee of Hull Corporation require a mains superintendent. Further particulars are given in our advertisement columns. Commencing salary £120 per annum, increasing by three annual increments to £150. Applications to the city electrical engineer (Mr. A. S. Barnard), Dagger-lane, Hull, by Wednesday, Dec. 21.

The Leith Town Council require three switchboard attendants. Applications to the town clerk (Mr. T. B. Laing) by 14th inst. See advertisement.

The Torquay Corporation require an arc lamp trimmer and an engine driver (for Willans' engines). Applications to the borough electrical engineer, Mr. P. Storey, by Tuesday, Dec. 13. See advertisement.

An experienced engineer is required to take charge of a large beam engine. Applications to Messrs. J. and J. Cash (Limited), Coventry. See advertisement.

An assistant lecturer in physics and mechanics is required at the Royal Naval Engineering College, Devonport. Salary £200 per annum. Applications to head master.

Mr. A. V. Anderson, assistant superintendent of mains at Edinburgh, has been appointed superintendent of mains in succession to Mr. S. E. Fedden.

Mr. W. C. Ullmann, of the British Thomson-Houston Co., has been appointed electrical engineer to the East Ham Town Council. Mr. Ullman is at present engaged on the Sheffield electric tramway contract.

Mr. Love has been appointed an assistant engineer at the Bath electricity works in place of Mr. Parsons, appointed to Halifax.

BUSINESS NOTICES.

Reference is made on p. 214 to correspondence which has passed between the Glasgow Corporation and a contracting firm with regard to the supply of telephonic apparatus. In connection with this subject, the following is of interest :—

"29, Waterloo-street, Glasgow, Dec. 7, 1898.

"Sir,—As you have published our letter of Nov. 25, 1893, to Sir James Marwick, Town Clerk, Glasgow, withdrawing our quotations of Sept. 23, 1897, for multiple switchboards, telephones, &c., we wish you to make it generally known that the contract made by Messrs. L. M. Ericsson and Co. (Limited), at Stockholm with the National Telephone Co. (Limited), London, was signed on Oct. 3, 1898, at Stockholm, without our knowledge or consent. The agreement made is not to sell telephone apparatus to or for any municipal corporation, or any licensee of Her Majesty's Postmaster-General, in connection with exchange lines, within the British Isles, except through the National Telephone Co. (Limited) at London.—We are, &c.,

"THE ERICSSON-BELL TELEPHONE CO.,
"Per Charles Bell, Sole Partner."

The business of the Waverley Electric Co., 117, George-street, Edinburgh, and at Portobello, has been transferred to Mr. J. G. Macandrew, 117, George street, Edinburgh, as from Nov. 28. Debts to date will be discharged by Mr. Mathew Buchan, 3, Victoria-terrace, Portobello.

Messrs. P. Jolin and Co. have removed from Narrow Wine-street to 25, Temple-street, Bristol.

BANKRUPTCIES, LIQUIDATIONS, &c.

A receiving order has been made against Edward B. Pym, electrical engineer, 29, Bramham-gardens, London, S.W., late of Bar Chambers, Scarborough.

At a meeting of the Mannesmann Tube Co. (Limited and Reduced) on Dec. 1 it was resolved that the company be wound up voluntarily, and Mr. E. Waterhouse, 44, Gresham-street, London, E.C., was appointed liquidator. A petition presented by George Senior and Sons (Limited) for the winding up of the company will be heard in the High Court on the 14th inst. A petition for the winding up of this company has also been presented by Messrs. C. G. R. Charubin, Arnold Wilhelm von Siemens and Georg Wilhelm von Siemens, and will be heard in the High Court on the 14th inst.

Claims against the Globe Electrical Advertising Syndicate (Limited) must be sent to the liquidator (Mr. T. C. Leman), St. Peter's Church-walk, Nottingham.

Claims against the London Provincial Electrical Co. (Limited) must be sent in to the liquidator (Mr. S. Wheeler, O.R.), 33, Carey-street, W.C., by Dec. 16.

Plant for Sale.—The plant, machinery and stock of electroplating and electric lighting works, in Blackburn, are for sale. See advertisement on another page.

Jandus Arc Lamp Patents.—The Jandus Arc Lamp and Electric Co. notify in our advertisement columns that they are prepared to negotiate for the sole right to manufacture the Pioneer arc lamp for use in England. Applications should be made to the sole agents, Messrs. Drake and Gorham, 66, Victoria-street, London, S.W.

Switch and Controller.—The General Electric Co. are placing on the market a lift controller and reversing switch with magnet control, for which special advantages are claimed. The form of resistance used with this controller is of tubular radiator type, with enclosed coils. In the construction of the reversing switch the arrangement consists of opening the circuit at 24 different points simultaneously, thereby dividing the sparking into many small arcs. The reversal of the current is accomplished by a half turn of the sprocket wheel.

Electric Fans.—The Kulm Hotel, St. Moritz, in the Engadine, is being fitted with an electric ventilating plant, current being taken from the private lighting plant at 200 volts. Mr. Ernest Hutton, Northallerton, Yorks., is the contractor.

Patent Amendment.—Notice is given in an advertisement in another column that Mr. G. W. C. Adams, of the Royal Naval College, Greenwich, Kent, has applied for leave to amend the specification of letters patent, No. 713 of 1888, for an improvement in voltaic or galvanic batteries granted to Theophilus Coad. Particulars of the proposed amendment are set out in the *Illustrated Official Journal* (*Patents*) of Nov. 30, and notice of opposition must be given within one month from that date.

Storage Battery Tests.—Following tests of a "Hart" cell have been made by the Electrical Standardising, Testing and Training Institution, and are of interest. The cell was charged and discharged four times at a current of 25 amperes, the discharges being considered complete when the open-circuit E.M.F. had fallen to 1·80 volts. The results of the measurements of the final charge and discharge are given in the following table :—

	Charge.	Discharge.
Mean current, amperes	25·0	25·0
Hours run	11·75	10·7
Ampere-hours	293	268
E.M.F. initial, volts	1·95	2·18
" final "	2·29	1·80
P.D. initial "	2·01	2·13
" final "	2·59	1·59
Mean P.D. "	2·26	19·2
Total watt-hours	662	514
Total weight of cell, kilos	47·5	47·5
Ampere-hour efficiency.....	91·5%	
Watt-hour "	77·7%	

The "Engineering Magazine."—The contents of the December issue of this magazine include, "Chinese Railway Development, Past, Present and Future," by Chas. Denby and E. P. Allen; "Equipment, Management, and Economic Influence of the Ship Canal," by W. Henry Hunter; "Old and New Forms of the

Digitized by Google

Suspension Bridge," by Gustav Lindenthal; "The Steel Foundation of the Ship Building Industry," by James Riley; "A Simple and Effective System of Shop Cost-keeping," by H. M. Norris; "The Buildings of Oxford from an Engineer's Point of View," by J. W. Parry; "Extensions of Submarine Telegraphy in a Quarter-Century," by Charles Bright; "The Application of Electric Power to Pumping Machinery," by Sterling H. Bunnell; "The Timber Wealth of Pacific North America," by Frank Haines Lamb; "Mining, Smelting, and Refining of Nickel," by Titus Ulke. The usual review of the World's Engineering Press is also included. Copies can be obtained at 1, 2 and 3, Salisbury-court, Fleet-street, London.

"Cassier's Magazine."—The contents of the December issue include: "Luxury in American Railway Travel," "Transportation and Lifting of Heavy Bodies by the Ancients," "High Explosives in Naval Warfare," "The Evolution of the Machine Tool," "British Four-Cylinder Locomotives," "The Vesuvius Cable Railway," and "Early Marine Engine Construction and Steam Navigation in the United States."

"Engineering Times."—We have received No. 1 of "The Engineering Times," published by Ward, Lock and Co. The magazine is well got up, somewhat on the lines of "The Engineering Magazine" and "Cassier's," though not on so ambitious a scale as these well-known magazines.

"Hazell's Annual."—We are pleased to receive the 1899 edition of "Hazell's Annual." This is the 14th issue of a useful record of men and topics of the day, and so far as a cursory glance at its contents shows, much additional matter of a useful and instructive character has been added to the new edition. Under several headings information is given relating to electrical and industrial schemes, and a brief review is included of electrical work during the past twelve months. Under the heading "Telephones" we are informed that the yearly subscription in London is from £10 to £17. The maximum figure is too low.

Electric Motor Cars and Carriages.—An excellent sheet of illustrations of the latest designs of electric motor cars and carriages, for which, it is stated, arrangements have been completed to manufacture in England on a large scale, reaches us from Messrs. Shippey Bros. (Limited).

"Trigonometry at a Glance."—Messrs. G. Phillip and Son have sent us a cardboard sheet, bearing the above title. The meanings and relations of the various trigonometrical functions are explained with the assistance of a travelling arm; and a comparison of the functions of an angle and its complement is facilitated by a rotating triangle of mica. Teachers may find this card useful when demonstrating the first principles of trigonometry.

Calendars Received.—"Pictorial Calendar for 1899" of the Peninsular and Oriental Steam Navigation Co., showing time of sailings and ports of call of the company's steamers.

The Gloucester Railway Carriage and Wagon Co. send us the "Gloucester Diary," which, although mainly published to advertise the manufactures of the company, yet contains a quantity of useful matter.

Exports of Electrical Apparatus and Material.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from Nov. 30 to Dec. 6, with the ports of destination:—

Argentina—Buenos Ayres, £1,427. *Australasia*—Adelaide, £55; Hobart, £20; Sydney, £1,189 (including £56 telegraph material); Wellington, £1,466 (including £1,287 telegraph material). *Belgium*—Ghent, £33. *China*—Shanghai, £285. *France*—Boulogne, £109. *Germany*—Hamburg, £110. *Gibraltar*—£774 (including £750 telegraph material). *Holland*—Amsterdam, £25. *India*—Bombay, £152; Calcutta, £1,775. *Japan*—Yokohama, £1,255. *North Atlantic*—£1,000 (telegraph cable). *Norway*—Christiana, £54. *Russia*—St. Petersburg, £57 (including £24 telegraph material). *South Africa*—Cape Town, £309; Durban, £348 (including £72 telegraph material); East London, £254; Port Elizabeth, £330. *Spain*—Barcelona, £115. *Straits Settlements*—Singapore, £9,192 (telegraph cable). *Sweden*—Stockholm, £40 (telegraph material). *United States*—Cienfuegos £397 (telegraph cable). *West Indies*—Trinidad, £36. Total, £20,807, against £33,449 in the corresponding week last year (Dec. 1 to Dec. 7).

Presentation.—On Friday last Mr. A. T. Cummins was the recipient of a handsome present on the occasion of his resigning the position of chief assistant engineer at Leyton electricity works. The presentation was made by Mr. H. C. Bishop on behalf of the engineering staff of the works.

MUNICIPAL, FOREIGN AND GENERAL NOTES.

Alleged Perjury.—At Bow-street (London) Police Court on Tuesday, before Mr. Lushington, John Limbrey Higgs, solicitor, Delahay-street, Westminster, again appeared to an adjourned summons charging him with having committed wilful and corrupt perjury in his examination in connection with the liquidation of the I. E. S. Accumulator Co. It was announced that Mr. Walton, an important witness, would not be able to give evidence for 10 days or a fortnight. For the defence it was pointed out that defendant, so far from having received any monetary benefit from his connection with the I. E. S. and other companies, was actually the poorer by a sum estimated at £12,000. He had interested himself in various electrical appliances, and, like most pioneers, had lost heavily. Mr. Higgs, it was urged, was not guilty of any intentional perversion of the truth, and that no case had been made out against him. Mr. Lushington left the matter to be decided by a jury, and committed defendant for trial, bail being fixed at two sureties in £100 each.

Anglo-Chinese Trade Enterprise.—The *Statist* is a journal likely to be exceptionally well-informed on matters telephonic in China and Japan. In a leading article in the last issue of that journal attention is called to the case against the municipal authorities of Shanghai in their treatment of the China and Japan Telephone Co. The object of the article is to show the treatment received by English trading firms in the Far East, and especially as a commentary upon the claim made in political circles for an extension of British enterprise in those regions. The following extract contains the pith of our contemporary's charge:—

Shanghai, as our readers are aware, is a town founded as a consequence of our wars with China. There is a British settlement and a French settlement, the British settlement being far the larger and containing considerable numbers of Americans, Germans and, in short, Europeans of all nationalities. The French settlement is almost exclusively French. Each settlement is administered by a municipality, and it is the action of the British municipality—which the French in this case follows blindly—in regard to the Telephone Company working in Shanghai which we would bring to the notice of our readers and commend to the consideration of Lord Salisbury. The fortunes of the China and Japan Telephone Co. have very little interest for the public, and we certainly should not intrude their affairs upon our readers were it not that the attitude assumed by the municipality is an object-lesson which, we venture to think, supplies a useful comment upon Lord Salisbury's policy in China. The Telephone Company has been working since 1883 or 1884 without any privilege of any kind, or, according to the municipality, any agreement even with the municipal authority. And it has gradually built up a business which, to put it briefly and clearly, the municipality now proposes to set up to auction, inviting capitalists all over the United States, all over the Continent, and here at home to bid eagerly for. The municipality has issued a little pamphlet, inviting tenders for the working of the telephone system in Shanghai, with an offer of a concession for 30 years, the municipality, however, to have the right of purchase at the end of 15 years. And in this pamphlet it gives such information as may guide intending tenderers. It is from this little pamphlet that we take the information we now propose to lay before our readers. The pamphlet tells us that at the time it was made up the company had 338 subscribers, and that these subscribers and such others as may be added before the concession is granted will be handed over to whomsoever is successful. Of course, we are aware that the municipality cannot compel these subscribers to join a new system. What the municipality means, no doubt, is to hold out an inducement to capitalists in Europe and America by telling them that there are already 338 subscribers to the existing company, and that no doubt these find the telephone of so much use that they will continue their subscriptions whoever may supply the service. Is not this a very plain expression of opinion that British enterprise in China needs neither encouragement nor protection; that British traders are very well able to take care of themselves; and that any of them who are fools enough not to take security for the safe enjoyment of whatever enterprise they may build up deserve to suffer? And remember that the expression of opinion is from the trading community of Shanghai. Again, it will be noted that the trading community of Shanghai invites Americans and the people of the Continent, without exception, to send in tenders. . . . It would be wearisome and serve no useful purpose to go into the various conditions imposed upon those who tender. But there is one point which throws so much light upon the allegation that encouragement and protection are required by merchants in China that we cannot refrain from noticing it. Those who send in tenders are obliged to state the charges they intend to make to subscribers. But the municipality reserves to itself the right to revise the terms if those who carry on the telephone business extend that business anywhere in China beyond the British and French settlements. It is hardly credible that any capitalist in his senses will agree to this. And therefore we do not expect that very many will tender. But as defining the very little importance attached by the British residents in Shanghai to either encouragement or protection the proposal is exceedingly instructive. The tenderer must first state what he intends to charge. And the charge, one would suppose, is the main point in the business, for nobody will carry on the telephone system except for the purpose of making a profit. Yet the tenderer, having stated what he requires, is told in the same breath that if he extends his business the municipality may change the terms altogether. Now, it is obvious that if China is about to be opened up and to advance economically, it may be of the very greatest importance to those who in future will carry on the telephone business in Shanghai to establish themselves in other great centres. But if they do so the threat is held over their heads that the municipality of Shanghai reserves to itself the right to alter the terms of the contract. Whether this is law we do not pretend to say. But, at all events, it is a very eloquent comment upon the alleged necessity that is felt for encouragement and protection.

Digitized by Google

Argentina Electrical Imports.—The imports of electrical plant and apparatus during the first nine months of 1898 were :—

	Value.
Galvanised iron wire (15,627 tons)	$984,227 gold.
Dynamos (44 tons)	30,740
Electric light mains (2,626 tons)	672,187
Fittings—gas and electric light (67 tons)	97,011
Electric light carbons (65 tons)	9,747
Incandescent lamps (12,104 dozen)	36,312
Electric light material (6,622 cases)	274,499
Telephone material (247 cases)	8,543
Telegraph material (635 cases)	18,953

Belfast.—The extensive premises of Messrs. J. Robb and Co., Castle-place, are now lighted electrically. The installation, which includes 40 Jandus arcs, has been provided by a local firm (Messrs. Coats and Co.) to the specification of Mr. J. H. Greenhill.

Owing to the great demand for current it has been decided to connect all applications already granted on the understanding, that if necessary the pressure of supply may be lowered to meet the extra demand pending erection of additional plant, delivery of which has been delayed.

Blackburn.—A sub-committee has been appointed to arrange terms with the consulting engineers (Messrs. Lacey, Clirehugh and Silliar) for the preparation (in co-operation with the borough electrical engineer) of a scheme for the extension of electric tramways in the district.

Buxton.—The District Council have obtained powers for borrowing £25,000 for electric lighting purposes.

Bromley (Kent).—The Bromley Electric Lighting Co. have notified the District Council that they propose laying electric lighting mains in several of the streets of the district.

Buluwayo.—In their annual report the Directors of Willoughby's Consolidated Co. (Limited) state that the contract for the installation of the electric light at Buluwayo had been completed and the electricity supply works taken over as a going concern by the Buluwayo Waterworks and Electric Light Co.

Carlisle.—The electric lighting installation at the Citadel Railway Station is now practically complete. The work has been carried out under the direction of the chief of the electrical department of the London and North Western Railway Co., Mr. J. W. Fletcher. In addition to 63 arc lamps for lighting the station proper and approaches, about 600 incandescents will be employed for lighting the interiors.

Chelsea (London).—At a special meeting of the Vestry last week it was decided, by a majority of one, not to proceed with the application for a provisional order for Kensal Town.

Chester.—A Local Government Board inquiry will be held on the 16th inst. into the application of the Town Council to borrow £20,000 for electric light extension purposes.

City of London.—The Common Council have informed the Smithfield Markets Electric Supply Co. (Limited) and the Charing Cross and Strand Electric Supply Corporation (Limited) that they cannot consent to the intended applications for provisional orders for the supply of electricity within the City which it was intended to make on behalf of those companies. A similar application by the Metropolitan Electric Supply Co. was refused a short time ago.

Copper.—The *Statist* for Dec. 3 contains an exhaustive article on "Copper Production," reviewing the position from 1879 to date. The figures given show that the world's production of copper in 1879 was 152,000 tons, against 396,000 in 1897—the largest output on record. The average price for the year 1879 was £57. 11s., against £48. 18s. 9d. in 1897—the highest price since 1891. In 1888 the price was £76 per ton. The United States contributed 212,000 tons to the 1897 total, Spain 54,000, other countries 130,000, the States output thus being far in excess of all other parts of the world. The diagram accompanying the review shows that the production in the States has been continuously increasing from 1879 to 1897, with exceptions only in 1886 and 1893. Having regard to the extent of the world's consumption of this metal the available stocks and supplies are smaller than ever previously in the history of the trade, at the present time amounting to only 26,879 tons, or approximately less than six weeks' consumption. Owing to the financial depression in the United States during 1895 and 1897, very large shipments of copper to Europe have been made from that country, but with the present indication of an expansion of business the outlook is (says the *Statist*) for an increase in the home consumption and for smaller supplies available for European and British requirements. The price of copper has improved 10 per cent. during the past four months, and our contemporary anticipates that the higher price will be maintained, if not increased.

Dewsbury.—The charge for current for motive power purposes has been reduced to 1¼d. per unit.

Dudley.—The Town Council have decided to oppose the application of the Midland Electric Corporation for Power Distribution for a provisional order. An agreement is to be entered into with the British Electric Traction Co. for relaying and electrically equipping the tramway from the railway station to the borough boundary.

Edinburgh.—The fine Library Hall of the Edinburgh University, which has been undergoing redecoration, is now lighted electrically.

Electrical Trades Union.—We are asked to state that the electrical workers of Glasgow are invited to attend a meeting on Monday evening next, at 79, Anderson-Cross, Glasgow.

Electric Pumping in South Staffordshire.—The Commissioners of the South Staffordshire Mines District have authorised the borrowing of £10,000 for providing electric pumps on the surface when a supply of electricity is available.

Electric Traction in West London.—The proposals of the London United Tramways for the extension of their system in West London, more particularly the suggested line between Hanwell and Acton, is exciting considerable attention. If the company are successful in their application there will be a continuous electric tramway from Uxbridge to the Central London Electric Railway at Shepherd's Bush. An illustrated pamphlet has been distributed by the Ealing Ratepayers' committee, setting forth the advantages of the projected Hanwell-Acton line.

Exeter.—At present there is an equivalent of 14,000 8 c.p. lamps connected to the electric light mains. The City Council have resolved to oppose the application for a tramway Provisional Order by the Exeter Tramways Syndicate, and have decided to municipalise the tramways and introduce electric traction.

Gold Coast Telegraphs.—During 1897 the permanent telegraph line to Kumassi was completed. The wires are mainly supported on trees, very few poles being used. Owing to increase of traffic, a duplicate land line has been established between Accra and Cape Coast Castle. There are 26 Government telegraph stations in the colony, which dealt with 84,580 messages in 1897. The responsibility for the maintenance of the line rests with the native chief through whose district it passes. It was found necessary to adopt this rule, owing to the thefts of telegraph wire and the destruction of telegraph property which had for some time prevailed.

Hammersmith (London).—The Vestry has invited other metropolitan Vestries and municipalities to assist in opposing the recommendations of the joint Parliamentary committee on the supply of electrical energy in the event of legislation being introduced to give effect to those recommendations. The Vestry contend that the local authority within the area of supply should have the power of deciding the route along which the mains are to be laid, and the right of breaking up and reinstating the roads, and also should retain its power of veto both in regard to overhead wires for traction and applications for provisional orders.

Hastings.—The Local Government Board have sanctioned the Town Council's application for a loan for the purchase of the undertaking of the Hastings and St. Leonard's-on-Sea Electric Light Co. (Limited).

Heckmondwike (Yorks).—There is a probability that the District Council will take electric current from the Dewsbury Town Council for street lighting purposes. A conference on the subject has been arranged.

Infirmary Lighting.—The proposal to put down an independent plant for the electric lighting of the new Islington Workhouse Infirmary at Highgate Hill provoked a heated discussion at the meeting of the Guardians last week. A report on the matter is to be prepared by an independent engineer, but it is probable that the Vestry will eventually obtain the contract for the supply of current.

Islington (London).—The work of laying electric light mains along Essex-road will be commenced in about a fortnight's time. The amount borrowed in connection with the Vestry's electric supply undertaking is now £191,300. There are at present 216 arc lamps in the parish, costing annually £6,822. 13s. 4d. The number of gas lamps displaced by these arcs was 440.

A number of letters from local subscribers and a memorial from the National Telephone Co. has been received by the Vestry against its proposal to compel the National Company to take down the telephone wires, the spans of which are longer than is allowed by the regulations. The memorial and letters asked that the company should be allowed to place its case before the Vestry. This matter is referred to in our report of the London County Council's meeting on Tuesday.

Kandy (Ceylon).—The agreement between the Municipal Council and the Colombo Gas and Water Co. for the electric lighting of this town has been signed. The contract for the plant will be placed in England.

Leeds.—The City Council on Wednesday decided to create Leeds Corporation Irredeemable Five per Cent. stock to the amount of £217,420. 10s. 4d., to produce by the dividends thereon the annuity referred to in Section 59 of the Leeds Provisional Order (1891). The Parliamentary committee has also been authorised to raise

Digitized by Google

and pay all additional moneys which may be or become due and payable by the Corporation to the Yorkshire House-to-House Electricity Co. (Limited) under the agreement for the purchase of the company's undertaking.

The salary of the tramway electrical engineer (Mr. John Burbridge) has been increased from £300 to £400 per annum.

Light Railways.—The Board of Trade have confirmed the order of the Light Railway Commissioners for the construction of a light (electric) railway from Summerhill-road, Bristol, to Hanham.

At a meeting of Preference shareholders of the Great Eastern Railway Co., Lord Claud Hamilton said that when the Light Railways Act was brought forward it was on the distinct understanding that light railways should be free from any liability to the restrictions such as the Board of Trade imposed with respect to main line and express trains, but it now appeared that the Board was desirous of imposing the same restrictions on light railways as were imposed on main lines. The Directors of the Great Eastern Company had arrived at the conclusion that if the Board persisted in imposing these restrictions it would be utterly impossible to consider the construction of light railways, because they could not be carried on without great inconvenience to the public and at a loss to those who had constructed them.

The Colne Town Council are taking steps to obtain an order under the Light Railways Act to construct and work a light (electric) railway within the limits of the borough.

The Board of Trade have sanctioned the order of the Light Railway Commissioners authorising the British Electric Traction Co. to construct a light (electric) railway between Middleton, Rochdale and Oldham. The Middleton Corporation appealed to the Board of Trade against the order on the ground that the procedure should have been taken under the Tramways Act, which offers a purchase clause more favourable to local authorities. This point has been overruled, and it is expected the tramway will be at once proceeded with. Application is being made to take the tramway within the boundaries of Oldham, Rochdale and Manchester.

Lincoln.—The Corporation have been approached on the question of purchasing the undertaking of the local tramways. The tramways company is considering the advisability of adopting electric traction.

Liverpool.—The City Council have authorised the Tramways committee to spend in the course of the ensuing year £127,400 in laying down on various routes rails suitable for electric traction—£54,839 for rails, laying and bonding, and the balance for paving.

Liversedge.—The District Council have decided to support the application of the British Electric Traction Co. for the construction of an electric tramway from Dewsbury to Cleckheaton.

Llanelly.—Now that the Town Council have been threatened by the Board of Trade with the revocation of their provisional order (1891) the advisability of complying with its terms is being considered by the Property and Estate Committee. Mr. J. C. Howell's offer to carry out the work has been again before the committee, and the Council are to be asked whether negotiations with Mr. Howell shall be reopened.

London County Council.—At Tuesday's meeting it was reported by the Fire Brigade committee that the installation of the electric light at the chief station of the brigade had been completed, and is in working order. The contract with the National Electric Free Wiring Co. provided for the fixing of a secondary battery, but the chief officer suggested that in place thereof a duplicate dynamo should be provided. The company had offered to provide and fix the dynamo, and to execute the work therewith for £274, and they recommended that a fresh contract be, therefore, entered into. This was carried.

The Council have postponed the consideration of a report of the Highways committee recommending that certain overhead telephone wires erected by the National Company in Islington (which exceed the span allowed by the regulations of the Vestry) be permitted to remain.

Lourenço Marques.—The General Electricity Co. of Lourenço Marques has secured the contract to light the streets of this town by six 1,000 c.-p. arcs and 300 16 c.-p. incandescents for £1,000 per annum.

Malvern.—The Board of Trade having notified the District Council that the provisional order granted in 1890 has not yet been put into force, it has been decided to ask the Board to grant a further extension of time for complying with the terms of the order.

Manchester.—A deputation of the Corporation paid a visit to Glasgow on Friday for the purpose of inspecting the New Springburn-Mitchell-street electric tramway. The deputation report that (1) the overhead trolley system is the only possible one for Manchester; (2) no nusiance or danger from it is experienced in Glasgow; (3) electric traction has proved so successful there that gradually it will supersede horse traction; and (4) half-penny fares for short distances are possible and profitable.

Oldham.—A town's meeting has declared almost unanimously in favour of the Council's tramway proposals, which comprise the taking over of the present lines and the construction of 12 additional miles of track at an estimated cost of £78,000. The Corporation have practically decided upon adopting electric traction throughout the entire system.

Penzance.—The application of Edmundson's Electricity Corporation for a provisional order is to be opposed, and the Town Council will itself apply for an order.

Personal.—Mr. C. H. Wordingham, Assoc. M. Inst. C.E., M.I.E.E., has been elected a member of the American Institute of Electrical Engineers.

Proposed Electric Ferry Across the Thames.—In the list of electric traction notices published in our last issue was mentioned a bill deposited by the Thames Ferry Co. for the purpose of incorporating a company to construct a ferry on submerged rails across the Thames, between Greenwich and Milwall, the ferry to be propelled electrically. The ferry would run from a point at or near the site of Brewhouse-lane, one chain or thereabouts to the west of the Ship Hotel, terminating in the parish of All Saints, Poplar, at or near the western boundary of the Island Gardens. It is proposed to take power to sell or lease the undertaking or any part of it to the Corporation or the London County Council or any corporate body, or to make agreements with such authorities with respect to the construction, management and maintenance of the undertaking.

Ramsgate.—A proposal to borrow a further £30,000 for the gas undertaking has led to a protest from Councillor Hart. At the last meeting of the Town Council he said it would be wiser to spend £30,000 or £40,000 in electric lighting, which must come eventually and, probably, would come before very long. There was considerable dissatisfaction in the town because of the absence of electric light. He was assured by his neighbours that gas destroyed their goods and that there was a general desire that the Corporation should establish electricity supply in the borough. He advised the Council to amend the proposal so as to include an application for powers to establish lighting by electricity. The Council did not take this advice. Ramsgate and Margate are the only southern seaside towns of importance without electricity works. Dover, Folkestone, Eastbourne, Hastings, Brighton, Hove, Portsmouth, Bournemouth and Torquay all have, and Bexhill, Plymouth and Southend will shortly have, supply works, so that if Ramsgate wishes to retain its position as one of the most popular resorts it will have to speedily follow the example of their enterprising and progressive rivals.

Rochdale.—There was no opposition at a Local Government Board inquiry held here on Wednesday into the application of the Town Council to borrow £30,000 for electric lighting purposes.

Rotherham.—The Council have declined an offer of the Drake and Gorham Electric Power Syndicate to construct an electric tramway between Rotherham and Rawmarsh.

Smithfield Club Show.—The centenary show of the Smithfield Club is being held this week at the Agricultural Hall, Islington, London, and while there is as usual very little to record of an electrical character some fine examples of agricultural machinery and engines suitable for electric lighting work are on show. Among the exhibitors whose stands attract the attention of visitors are Messrs. Clayton and Shuttleworth, Crossley Bros., John Fowler and Co., E. S. Hindley, R. Hornsby and Sons, Marshall, Sons and Co., Robey and Co., and Ruston, Proctor and Co. on the ground floor, while in the gallery are the excellent exhibits of Messrs. W. H. Willcox and Co. Amongst the machines on show by Messrs. Robey and Co. is a "Robey" gas engine fitted with patent self starter, and specially constructed for electric lighting work, a suitable governor being specially provided; also a "Robey" under-type combined engine and locomotive boiler, which is claimed to be extremely economical in fuel, consuming under 2lb. of Welsh coal per indicated horse-power per hour. Special care has been taken with the working parts of this engine, so that it may be relied upon to run safely and economically at high speed. The lubrication of this engine renders it particularly suitable for long runs. Messrs. John Fowler and Co.'s exhibit at Stand No. 7 consists mainly of agricultural machines, but also includes an assortment of models and samples of patent light railway plant and rolling stock, the exhibition space available not being sufficient to enable the firm to display a full-size exhibit. Messrs. W. H. Willcox and Co. show a large collection of tools and general engineers' stores, and the show of belting, lubricants, steam engine fittings, and boiler mountings, &c., &c., invite the special attention of those visitors who own or tend running machinery. Included in this firm's exhibit is a selection of patent roller bearings, Messrs. Willcox and Co. having been appointed sole agents to the Roller Bearings Co. (Limited), for the east, south, west and midland counties and London. Evidence of the plethora of work in the engineering trades is manifest, a number of the exhibitors, including Messrs. Robey and Co., having experienced difficulty in providing the necessary machines for show. In some cases customers have consented to their machines on order being exhibited at Islington, accepting delivery direct from the show.

Salford.—On the recommendation of the Electric Light committee, the Corporation have decided to appoint a consulting electrical engineer. Mr. Haworth, chairman of the committee, in supporting the recommendation, said that they wanted someone to go through their specifications, and he would like this to be an outsider. Sir Richard Mottram thought it was most important, when they were spending £200,000, that they should spend it under the best possible advice. He had confidence in both the committee and the engineer, but, at the same time, if they passed the resolution, he thought it would be their duty to get the best of experts.

Sheringham (Norfolk).—It has been decided to adopt the Lighting and Watching Act. The surveyor (Mr. C. D. Watts) has submitted to the Parish Council estimates of the cost of electric and gas lighting, and it is probable that the former will be adopted.

South Africa.—The *British and South African Export Gazette* says the question of the erection of electricity supply works at Uitenhage is under discussion. A proposal has been made to utilise water power in the generation of current.

The Bloemfontein Town Council have decided to extend their contract with Messrs. Reunert and Lenz for the electric lighting of the borough so as to provide for supplying current to the whole town, the cost to be over £17,000, instead of £7,500.

The Johannesburg Town Council have accepted the tender, amounting to £11,100, of Messrs. Siemens (Limited) for the electric lighting of Old and New Doornfontein.

A complete electrical installation has been fitted up at the Dunraven gold mine, Rhodesia.

Stanford-le-Hope (Essex).—Some time ago, the Parish Council entered into an agreement for the electric lighting of the district, but the County Council refuse to sanction the laying of mains unless the Parish Council guarantee to make good the roads, &c. This, however, they object to do, unless the contractor (Mr. Simpson) agree to indemnify them against any claims of the County Council.

Telephone Municipalisation.—The Parliamentary Bills committee of the Glasgow Corporation have decided to amend their Telephone Bill by inserting a clause pledging the Corporation Loans Act, in addition to the Common Good Fund, as security for the carrying out of the municipal telephone project. By this means the guarantee rate under the Corporation Loans Act will be employed to secure principal and interest, and, if necessary, an assessment can be imposed for the purpose.

Torquay.—Ald. Kerswill presented a statement at the meeting of the Town Council on Tuesday on the cost of the electricity supply scheme. He said that the works could now give a constant supply of current. The total outlay was £24,867, or £1,726 over estimated cost. From the £24,867 had to be deducted £920, value of material available for the extension of the mains, reducing actual cost to £23,946. The amount sanctioned and borrowed for the undertaking was £22,300, so that the works have cost £1,646 16s. 1d. more than the sum borrowed. The Borough electrical engineer (Mr. P. Storey) reported that when the works were opened there were 40 consumers, now there are 95, and 14 applications were awaiting connection. The revenue from March 17th to Sept. 29th was £1,091.

Underground Electric Railways in London.—It is reported that opposition is to be made to the applications for authority to construct the Great Northern and Strand and the North-West London Electric Railway. The London County Council will be asked by several local authorities to oppose the schemes on the ground that no further electrical underground railways should be sanctioned until the already authorised lines are constructed, and their effect upon the relief of traffic in London is ascertained.

Wakefield.—The Electric Lighting committee are considering the question of extending their arc lighting system.

Whitechapel (London).—The District Board of Works, on Monday, decided to establish electricity supply works, and to borrow £60,000 for carrying out the scheme, which has been prepared by the consulting engineer, Mr. Arthur Wright, of Brighton.

Wolverhampton.—The Electricity Department of the Town Council have more applicants than they can conveniently supply. Four months ago the Council decided upon an extension scheme involving an expenditure of about £30,000, but it is anticipated that it will be at least six months before this additional plant will be available. As a means of relieving the strain on the resources of the lighting station, it has been decided by the Markets committee to have the old gas fittings in the market hall restored, so that, if necessary, the large arc lamps which supply the general lighting of the building may be temporarily cut off in the evening for an hour or so without serious inconvenience.

Worthing.—Mr. E. W. Monkhouse has been instructed by the Electric Light Committee to prepare a report upon the question of erecting a refuse destructor in conjunction with the projected electricity supply works.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by Mr. J. C. CHAPMAN, *Fel. Chartered Inst Patent Agents, of 70, Chancery-lane, W.C., from whom all information on he subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete Specifications. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

November 11, 1898.

23,821. A. E. GILLESPIE and J. GILLESPIE. London. Improvements in and relating to coin freed telephones.

November 12, 1898.

23,827. G. D. BURTON. London. Improvements in the art of electric dyeing and shrinking and in apparatus therefor.*

23,853. S. F. WALKER. Cardiff. Improvements in primary galvanic batteries.

25,890. A. HÄNSEL. London. Improvements in electric velocipedes or other vehicles.

23,895. A. M. CLARK. London. Electric ignition apparatus for internal combustion engines. (La Société Anonyme des Automobiles Pengcot, France.)

November 14, 1898.

23,922. R. LORD and A. R. MILLER. Swindon. Improvements in fire alarms or boxes from which electric signals are given in case of fire.

23,937. J. ATKINSON. Cheshire. Improvements in electrical dynamos and motors.

23,958. THE BRITISH THOMSON-HOUSTON CO. (LIMITED). London. Improvements in electric measuring instruments. (E. Thomson, United States.)*

23,976. P. L. GUYENOT. London. Improvements in and relating to electrically-controlled taps or cocks.

23,988. W. P. THOMPSON. London. Improvement in or relating to coin-controlled telephones. (C. H. Kahrs, Norway.)*

24,005. A. J. BOULT. London. Improvements in electrical storage batteries. (Sedneff and Bratasched, Germany.)

November 15, 1898.

24,030. H. RICHARDSON. Birmingham. Improvements in weighing apparatus and electrical weighing machinery.

24,037. A. WATSON. Birmingham. Improvements in electrical switches.

24,051. J. M. MURPHY. London. Improvements in electric switch mechanism.*

24,052. J. M. MURPHY. London. Improvements in electric railway systems.*

24,053. J. M. MURPHY. London. Improvements in roadway structures for electric railways.*

24,055. R. SNOW and DAVY BROS. (LIMITED). London. Improved means of cooling electric machines.

24,155. C. SCHMIDLIN. London. An improved electricity meter.

November 16, 1898.

24,126. R. G. HISLOP. Edinburgh. Improvements in junctions for tubes used as conduits for electric wires.

24,133. H. HIRST and H. BEVIS. London. A new or improved open or enclosed arc electric lamp.

24,164. W. H. BRADLEY. London. An improvement in electric incandescent lamp shade holders and a device for use in connection therewith.

24,171. H. SCHLOSS. London. Improvements in voltaic cells having dry plates which may be regenerated.*

24,172. H. SCHLOSS. London. Process for obtaining a permanent electrical contact at the covers of voltaic cells.*

24,196. C. H. KAHRS. London. Electrically heating plates, dishes and the like.*

24,210. H. H. LAKE. London. Improvements in the manufacture of electrodes for secondary batteries. (v.d. Poppenburg's Elemente und Akkumulatorenfabrik, Wilde and Co., Germany.)

SPECIFICATIONS PUBLISHED.

NOTE.—All Specifications can now be obtained at the uniform price of 8d. each.

1897.

27,707. HARTLEY and HARTLEY. Electro-metallic depositing apparatus.

28,823. PRICE and JOHNSON. Covers, caps and lids of gas, sewer, telephone and electrical supply shafts and holes, gullies and the like.

30,427. HOWELL. Metallic ribbon, particularly adapted for battery plates, but useful also for other purposes.

30,544. PARPART. Electric welding of tubes and apparatus therefor.

1898.

4,278. BUSHER. Railway electrical signalling apparatus.

11,075. WISE (The Moore Electrical Co.). Electrical apparatus for producing luminous or similar effects such as Röntgen rays from exhausted receivers.

17,692. VON MÜLMANN. System of reflectors for double globe electric arc lamps.

18,941. ABEL (Allgemeine Electricitäts Geselschaft). Manufacture of homogeneous mixtures for the incandescence bodies of electrical glow lamps.

COMPANIES' MEETINGS AND REPORTS.

London Electrical Cab Co. (Limited).

The ordinary general meeting of this Company was held on Monday, at the Westminster Palace Hotel, Mr. H. H. MULLINER presiding.

The SECRETARY (Mr. W. John Wood) read the notice calling the meeting.

The CHAIRMAN said: Some of you may remember that at the statutory meeting our *modus operandi* was fully explained, and it was then pointed out that, in the opinion of the Directors, it was certainly advisable, even at the risk of being blamed for not getting to work quickly enough (that is to say, not getting out a large number of cabs), to proceed with the greatest caution. Nothing would have been easier than to put in hand a large number of cabs, but in a new industry like this it would have probably meant that we should have found other improvements advisable, and ourselves in the awkward position of having spent our capital, and not have had perfect cabs. We commenced by building 12 cabs, which did not prove to be perfect for our requirements. Some of these cabs were altered, and we built more new ones, until we had twenty-four in use. The public "caught on," and these cabs were in enormous demand; they were used probably much more than any hansom with two horses to work it in London. They were a great improvement, but still we were not satisfied. We started a system of entering every complaint and every breakdown, however trivial, and the number of these breakdowns and complaints at the time made us all very unhappy; but we went to the bottom of each complaint and localised the reason, and found at least nine-tenths arose from five different causes. It would not be policy to go too minutely into what these causes were: four of them were mechanical or electrical, and the fifth, which was one of the most serious, was the rubber tyres. The result of our energy in localising and remedying these complaints has been that we do not now have one-fiftieth of the breakdowns or troubles that we were having. We experimented with six or seven different sorts of rubber tyres with more or less success, but I think we have now hit upon one which will get over our trouble. The makers also seem confident about it, as they propose guaranteeing their durability for nine months. You may have noticed that our cabs now make slightly more noise than at first. This is owing to the chains which we have had to substitute for those employed at first. Mr. W. H. Preece congratulated us in his inaugural speech particularly on the chains we were then using. We found, however, that they would not stand the severe regular use, and had to be substituted by the present ones. We also had considerable trouble with our drivers; but I am pleased to say things are now on a friendly footing between us, and I believe neither side has any grievance against the other. All the drivers are now paying the full Asquith award without any reduction, and I think this is more than can be said in any other cab yard in London. The intention of your Directors is in future to do all they can to develop the private hire trade; that is, supplying carriages for a fixed term such as by the day, week or month. They believe it will prove more profitable by saving wear and tear, saving the Scotland Yard licenses, and obtaining a slightly increased price. We have some customers (for example, Prince Henry of Orleans) who much prefer our cabs to any form of horse-driven vehicle, and are willing to hire them for extended periods. We believe there are many others who will also be glad to do so, as soon as it is known that we are in a position to supply them. Of companies to deal with electrical carriages alone, I have heard of five or six being started, but I have yet to hear of one single successful vehicle which has been built, or any practical result which they have obtained. It has been pointed out to your Directors many times that our cabs should have been built differently in several respects. Perhaps so. What I can tell you is that a company has been formed in Paris who are working practically exactly the same vehicle under the same patent as we have now in this Company, and before they started they announced that their cabs would be a wonderful improvement on ours. However, after an immense number of experiments and experts' opinions, they decided to build their cabs absolutely and identically as those we are now using, and they have now nearly completed 100 cabs. We have heard a great deal about the French being the pioneers of the motor industry, but as far as electrical vehicles are concerned, they are absolutely the copyists of this Company. Now, I must tell you of our troubles with the electric current and the accumulators. We started with contracts from the London Electric Supply Corporation for current, and with the Electrical Power Storage Co. for cells, and the contracts were drawn up with the very greatest care, but electricity and accumulators are things which are not amenable to contracts, as the unforeseen always happens. I consider we have been badly treated by the London Electric Supply Corporation. Possibly we might have won after a law suit, but it would have been a very big one. However, we have given notice to terminate our agreement with them, and have laid down an installation for manufacturing our own electricity. A plant such as this takes a long time to complete, however, but it has been in working order for the past month and appears extremely satisfactory. Our current is not now costing us a quarter of the amount which it was actually costing us before. I say "actually," as owing to only being able to obtain it during prescribed hours, loss through cells standing hungry or "sulphating," loss owing to transmission through motor generators, extra charges for lighting, &c., the "actual" cost was very different to the nominal one. Had we obtained our current at the same cost that we are now doing, the loss in the balance sheet would have been much reduced. However, this loss will not happen in future. We had to go to a very large expense in purchasing motor generators, but I am pleased to be able to tell you that through the good offices of our consulting engineer, Mr. Manville, we have been able to get rid of these without any loss.

Now, as regards accumulators: My remark about the impossibility of controlling electricity by means of an agreement applies even still more in this case. After innumerable difficulties, discussions and threatened law suits with regard to the guarantee, we have now practically settled upon a working basis which we believe will prove satisfactory to both parties. A scheme for not purchasing any more accumulators, but hiring them at practically the cost as maintenance now amounts to, is occupying the earnest attention of your Directors. This will decrease the amount standing in the balance-sheet under "contingent liabilities," and will give us more working capital. I ask you not to insist on my discussing accumulators too fully, as doing so might prejudice us in sundry pending negotiations. But I certainly can state that accumulators will not prove the impossible barrier to our success which so many kind friends confidently predicted. Your Directors have realised for some time that the days for experiments and tests have gone by, and that the undertaking being now a purely commercial one, a manager must be appointed who could be always there looking after your interests. Such a manager, however, must have a considerable electrical knowledge, and we have every reason to think that Mr. J. Grice Statter, who has been appointed, and whom you will meet if you visit the Company's premises, combines that electrical and commercial knowledge; in fact, personally, I fully believe that Mr. Statter will do much towards the ultimate success of this Company. With regard to the Company's finances, the capital of the Company is £150,000, of which about £75,000 was subscribed. The condition made by the Directors before going to allotment was that the amount paid in cash to the vendors should be in exactly the same proportion as stated on the prospectus (one-third). The vendors have therefore received about £25,000. As to our new cabs, we are not satisfied that these ride as comfortably as they ought to, notwithstanding the extra springs with which they are fitted. This, however, is a fault of the makers which will be put right without charge as soon as possible. We believe that all the cabs will be in working order and regular use by the middle of January. As stated in the report, it is proposed very shortly to make an issue of debentures. We believe that £12,000 will be amply sufficient, but, in order to be on the safe side, this will be part of an issue of £15,000 which remains to be issued at a future period if required. This issue will be made in 500 debenture bonds of £20 each, at 5 per cent., 50 redeemable each year, paying off the whole amount in 12 years. The loss stated in the balance sheet of £6,207. 15s. 6d., although stated as a trading loss, must not be looked upon quite in that light. This balance sheet covers a period of 20 months, and all the losses which I have referred to in connection with construction, experiments, &c., have occurred during that time. This loss no one can deplore more than your Directors, especially considering the different results which we hoped for and which were foreshadowed in the prospectus. But we did not then possess the knowledge we have since acquired from the experience of running electrical cabs 50 miles a day for nearly two years. I am informed that our cabs have run nearly 200,000 miles; nothing approaching this has ever been done before with accumulators. That experience has cost us a great deal, but it is experience which we believe will prove a very valuable asset. I am as certain as I was when this Company was first formed that electrical traction is the future motor power for trade vehicles in London. This Company has had, and will have, difficulties to contend with; the same as every pioneer company is bound to have; the same as the pioneer company supplying electric light in London has had. I think we may congratulate ourselves on the approach of the end of our troubles. Our expenses are now enormously reduced; from the experience we have had we realise what really is required, and we confidently believe that when we meet you next year we shall be able to show a very far more satisfactory result. I now move that the report and statement of accounts to July 31, 1898, be received and adopted.

The Hon. REGINALD BROUGHAM seconded the motion, which, after a short discussion in which the Directors were blamed for not calling the shareholders together earlier, was adopted.

The re-election of the retiring Directors and a vote of thanks to the Chairman for presiding terminated the proceedings.

Cape Electric Tramways (Limited),

The first ordinary general meeting of this Company was held yesterday under the presidency of Col. Sir CHARLES EUAN-SMITH, K.C.B.

The SECRETARY (Mr. S. W. Jameson) read the notice calling the meeting, and the report of the Directors was taken as read.

The CHAIRMAN said: Gentlemen, the Directors may very safely congratulate you not only on the results of the past year's working, but on the very solid prospects that this Company has of assured prosperity and success. The dividend of 5½ per cent. that has been paid on the Ordinary shares is, in the opinion of the Board, a gratifying return for the first twelve months' work of a concern which is, as we hope and believe, strengthening its claims to universal popularity, and this dividend has been paid after provision made for many considerable and, more or less, unforeseen expenses incidental to the formation of a Company of this magnitude, and the commencement of the working of a new system. The extensions that have now been decided on, and the expenses of which will be met from the issue of the remaining £25,000 Debenture stock, will, of coure, result in, as we hope, bringing a very substantial increase to the revenue of the Company. The principal care of the Directors is to maintain your property in a state of the highest possible efficiency, to practice all desirable economies, and in every possible way to endeavour to meet the just demands of the public convenience. They believe that during the year under review they have not been unsuccessful in securing these ends, and they hope on the occasion of the next annual meeting they may have to submit to you a still more satisfactory result of their labours. I now move the adoption of the report and accounts.

Mr. BUTLER seconded the motion.

Digitized by Google

Mr. PAGE suggested that the accounts of the local companies should be published. He asked what would be the position at the end of the concession, as only a certain amount of capital had been spent on the tramways, and the balance was "in water," while the reconstruction of the lines would require a large sum ?

Mr. BUTLER reminded the meeting that the cost of the concession purchased from himself, which was a considerable sum, must be taken into account in regard to capital expenditure.

Mr. GARDNER said that there was a rumour that the Port Elizabeth tramways did not pay, and he would like the Chairman to contradict it.

Mr. PARISH (a Director), in replying to the remarks of Mr. Page, said that the position was that when the municipalities purchased the tramways they had both in the case of the Port Elizabeth and the Cape Town to pay for goodwill, and 20 years hence the amount of goodwill would be very considerable. In that time the size and population of Port Elizabeth might be expected to double, and, as regarded Cape Town, the city must extend on both sides of the grand trunk line that ran from Wynberg through Cape Town to Seaport. The Port Elizabeth Company was earning £11,000 a year, and would do still better, and the rumour referred to was utterly without foundation. He saw no objection to the local accounts being published, as they would establish the fact that the state of affairs was even better than at first sight appeared. In 1902 they would begin the amortization of the Cape Town mortgage, which would then be reduced year by year on a sliding scale. The current year, so far, had proved most satisfactory, and for the first five months from July last they showed an increase of £7,245 over last year, or nearly 2 per cent. upon the shares.

The report was adopted and the dividend approved, and a vote of thanks to the Chairman, Directors and staff terminated the proceedings.

West India and Panama Telegraph Co. (Limited).

The report of the directors of this company for the half-year to June 30 last states that the amount to credit of revenue is £39,612. 14s. 2d. against £38,209. 14s. 4d. for the corresponding half-year of 1897, and the expenses have been £21,704. 17s. 5d. against £21,426. 17s. 10d., leaving £17,907. 16s. 9d., which, with £721. 10s. 10d. brought forward, makes £18,629. 7s. 7d., with which it is proposed to deal as follows :—

First Preference Shares—Dividend, six months to June 30, 6s. per share	£10,368	18	0
Second Preference Shares—Dividend, six months to June 30, 6s. per share	1,400	14	0
Ordinary Shares—1s. 6d. per share (free tax)	6,624	1	6
Balance forward	235	14	1
	£18,629	7	7

The shareholders will be glad to know that during the recent war in Cuba and Porto Rico, the cables landing in those islands were maintained in good working order, enabling the company to handle an increased volume of traffic arising from press and official messages.

The traffic receipts for the six months, compared with the corresponding period of 1897, show an increase of £6,738. 2s. 9d., and the revenue of the current half-year is also considerably in excess of that for the corresponding period, but is tending gradually to resume its normal limits. The expenses of repairing cables amounted to £8,907. 3s. 4d., or £143. 3s. 9d. more than those for the corresponding period.

New cables referred to in the last report have been successfully laid between Grenada, St. Lucia and St. Croix, in substitution for the old Trinidad-St. Croix line, and that the Trinidad-Grenada section has also been duplicated. The laying of these cables has considerably strengthened the company's duplicate system.

In September a disastrous hurricane passed over Barbados and St. Vincent, causing great loss of life and property and wide-spread suffering and distress. Feeling confident of the shareholders' approval, the directors immediately forwarded to the Lord Mayor's relief fund a donation of 250 guineas in order to express the sympathy of the company in the heavy calamity that had befallen those islands. The messages relating to the relief of the distress have been sent free of charge over the company's system, and the directors succeeded in having this privilege extended across the Atlantic. Two of the company's cables at St. Vincent were interrupted, and the land lines in Barbados, St. Vincent and St. Lucia were wrecked by the hurricane, entailing considerable expense for repairs.

NEW COMPANIES, STATUTORY RETURNS, &c.

BRITISH SCHUCKERT ELECTRICAL CO. (LIMITED).—This company was registered on Dec. 3, with a capital of £200,000, in £10 shares, to carry on, in Great Britain and her colonies and dependencies, the business of electrical and general engineers, suppliers of electric light, heat and power, electrical contractors, manufacturers of and dealers in plant, machinery, engines, appliances and implements connected with the supply and use of electricity, mechanicians, metal workers, copper smelters, cable and wire manufacturers, &c. The first subscribers, with one share each, are :—Major-Gen. H. Alderson, Major P. A. MacMahon, F. Manuelle, E. Kraftmeier, F. T. Eggers, H. E. Golding and H. J. C. Wells. The first Directors are :—Major-Gen. Sir H. Alderson, K.C.B., A. Hassler, Major P. A. MacMahon, F.R S., E. Kraftmeier, F. Manuelle and F. T. Eggers (managing).

DOULTON AND CO. (LIMITED).—This company was registered on Nov. 29, with a capital of £750,000, in £1 shares (of which 350,000 are £5 per cent. cumulative Preference), to acquire the business carried on as Doulton and Co. at Lambeth Pottery, London, at Rowley Regis and Burslem, Staffs., and elsewhere, to enter into an agreement with Mr. Henry L. Doulton, and to manufacture, sell and deal in Doulton ware, bricks, tiles, electrical and art pottery, &c. The first Directors are :—Henry L. Doulton, Ronald D. Doulton, Benjamin Hannen and William A. Turnbull.

ELECTRIC AUTO-MOBILE SYNDICATE (LIMITED).—This company was registered on Nov. 29, with a capital of £900, in £10 shares, to acquire, develop, work and deal with any patents, concessions, inventions, &c., and to manufacture, sell, let on hire and deal with electric vehicles, motors, machinery, &c.

HIRAM S. MAXIM ELECTRICAL CORPORATION (LIMITED).—This company was registered on Nov. 30, with a capital of £250,000, in £1 shares, to enter into an agreement with the Hiram S. Maxim Electric Lighting and Engineering (Pioneer) Syndicate (Limited), to acquire a certain invention of Mr. Hiram S. Maxim, and to carry on the business of electricians, electrical and mechanical engineers, suppliers of electricity and manufacturers of and dealers in electrical apparatus and plant. The first subscribers, with one share each, are :—M. E. Williams, J. de Meray, M. Devenish, G. Neville, G. Terrell, F. A. English and A. H. English.

INDIAN MICA CO. (LIMITED).—This company was registered on Dec. 2, with a capital of £30,000, in £1 shares, to acquire and develop certain leases and concessions over a tract of land containing mica or mica mines in the district of Hazaribagh, Bengal, or elsewhere. The first Directors are : Sir James Pender, Bart., M.P., C. A. S. Bedford, E. R. Calthorp, Col. H. L. Mitchell, Surgeon-Gen. Annesley, C. C. de Renzy and C. W. Wallace.

TELEPHONE CONSTRUCTION CO. (LIMITED).—This company was registered on Dec. 1, with a capital of £20,000, in £1 shares, to enter into an agreement with Mr. G. Hooper, to carry on the business of a telephone, telegraph and electric light, heat and power supply company, and to establish, work, manage and control telephone exchanges and electric light works. The first subscribers (each with one share) are :—Louis Schramm (electrical engineer), Wm. G. H. Monypenny, R. Curzon, G. Hooper, J. H. Steinhardt, J. A. Brymer and J. Phillips.

CITY NOTES.

MEMORANDA.—Bank rate 4 per cent. (since Oct. 13, 1898). Price of silver 27½d. per oz. (Dec. 8). Consols (2¾ per cent.) 110¼—110⅜ for money, 110 1/16—110 1/16 for account ; 2½ per cent. 104¼—104¾ (Dec. 8), Stock Exchange Settling Days : Stocks and Shares Continuation Days, Dec. 13 and 28 ; Ticket Days, Dec. 14 and 29 ; Pay Days, Dec. 15 and 30 ; Mining Share Carry-over Days, Dec. 12 and 27.

ALLGEMEINE ELEKTRICITATS GESELLSCHAFT.—The annual meeting of this company was held at Berlin on Saturday. It was stated that the value of the new orders in hand at the beginning of the new financial year amounted to about £5,700,000, and that a further extension of between £2,000,000 and £3,000,000 could be anticipated if the contract with the Berlin municipality was definitely accepted. The experiments made with the new Nernst lamp have, it is reported, been successful.

BRAZILIAN SUBMARINE TELEGRAPH CO (LIMITED).—The Directors of this company have declared an interim dividend of 3s. per share (or at the rate of 6 per cent. per annum) free of tax, for the quarter ended Sept. 30, payable on 23rd inst. The transfer books will be closed from 16th to 22nd inst. inclusive.

BROMPTON AND PICCADILLY CIRCUS RAILWAY COMPANY.—Mr. J. Staats Forbes has been elected chairman of this company.

CANADIAN, BRITISH COLUMBIAN AND DAWSON CITY TELEGRAPH CO. (LIMITED).—The prospectus of this company, which is formed to construct a telegraph line to Dawson City, will be issued in a day or two. As will be seen by an announcement elsewhere, the directorate includes, amongst others, Sir James Grant, K.C.M.G., of Ottawa ; Sir Adolphe Cavon, K.C.M.G., M.P., ex-Postmaster-General of Canada ; and the Hon. J. H. Turner, ex-Premier of British Columbia. Sir Thomas Tancred, Bart., is consulting engineer, and Mr. E. G. Woodford (late State Engineer of the Transvaal) will be resident engineer. We understand that only an issue of Debentures will be offered to the public for subscription.

COMMERCIAL CABLE CO.—A quarterly dividend of 1¾ per cent. and a bonus of 1 per cent. has been declared, payable on Jan. 3, out of the net earnings of this company. The transfer books will be closed from the 21st inst. to Jan. 3 inclusive.

DOULTON AND CO. (LIMITED).—Conformably to the particulars given in our last issue, subscriptions have been invited this week to an issue of 233,334 Five per Cent. Cumulative Preference shares of £1 each and £233,334 First Mortgage Four per Cent. Irredeemable Debenture Stock in Doulton and Co. (Limited), which has been formed to acquire the business and property of the well-known firm of Messrs. Doulton and Co. This issue is for the balance of a total capital of £1,100,000, the remainder being taken by the vendor, Mr. Henry Lewis Doulton, who becomes chairman and managing director of the new company. The business was established in 1815 by the father of the late Sir Henry Doulton. The recent death of Sir Henry and the consequent withdrawal of a portion of his capital has determined Mr. H. L. Doulton to transfer the business to a joint stock company. The management and policy of the business will remain as hitherto. The business is taken over by the new company from Jan. 1 next. The vendor guarantees that the stock-in-trade, book debts, cash balances and other floating assets on that day shall not be less than £400,000. A valuation of the company's properties, plant and fixed machinery, has been made to the value of £663,000. The average annual nett profits are certified at over £67,127, the profits of each year being in excess of the year preceding. As part payment of the price to be paid for the various properties, including working capital and goodwill, &c. (£1,100,000), the

Digitized by Google

vendor takes £116,666 in fully paid Preference shares at par, £166,666 in fully-paid Debenture stock at par, £400,000 in fully-paid Ordinary shares at par, and £466,668 in cash. These is no waiver clause in the prospectus, except for purely trade contracts. The list closed on Wednesday.

EASTERN TELEGRAPH COMPANY (LIMITED).—This company announce the payment on Jan. 16 of dividends at the rate of 3½ per cent. per annum, less tax, on the Preference stock of the company for the quarter ending Dec. 31, and an interim dividend of 1¼ per cent. on the Ordinary stock, free of tax, in respect of profits for the quarter ended Sept. 30. The tranfer books will be closed from Jan. 9 to 16 inclusive.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH CO. (LIMITED).—The directors of this company have declared an interim dividend for the quarter ended Sept. 30 last, of 2s. 6d. per share, free of income tax, payable on Jan. 14 next. The share register will be closed from 6th to 13th prox. inclusive. The coupon on the company's Fifty per Cent. Australian Government Subsidy Debentures, due on Jan. 2nd next, will be paid on and after that date by Messrs. Barclay and Co., 54, Lombard-street, E.C. Coupons must be left three days for examination.

GREAT HORSELESS CARRIAGE CO. (LIMITED).—The Directors of this company have compromised the action brought against them by a combination of shareholders, by which the shareholders referred to receive, in three instalments, 16s. in the £. Similarly, the actions brought against Mr. Geo. Salter and the late Earl of Winchilsea were compromised before the death of the latter. Other shareholders in the Great Horseless Carriage Co. may now feel emboldened to come forward and press their claims for reimbursement of their subscriptions on the ground of misstatements in the prospectus.

RICHARD HORNSBY AND SONS (LIMITED).—At the ordinary general meeting the chairman (Mr. H. S. Gee) said the result of the year's operations were satisfactory. Their works had been fully employed. They had made a profit of £37,827 after writing off the usual depreciation and paying interest on debentures and mortgage loan and directors' remuneration. The Directors recommended the payment of dividends on Preference stock of 6 per cent. (including arrears) to Sept. 30, and 6s. per share on the Ordinary shares. £5,000 was placed to reserve and £2,137 carried forward. They had sold some £50,000 more of machinery than in the previous year.

IPSWICH TRAMWAYS CO. (LIMITED).—The Directors of this company have decided to sell their undertaking to the Drake and Gorham Electric Power and Traction Syndicate for £30,000. The lines are to be equipped on the overhead trolley system.

LONDON ELECTRIC SUPPLY CORPORATION.—The transfer books of the Four Per Cent. First Mortgage Debenture stock of this company are closed from 12th to 31st. inst., inclusive.

NATIONAL TELEPHONE CO. (LIMITED).—The Directors of this company have decided to make a further issue of £330,000 Three and a-Half Debenture stock, forming part of a total limited to £2,000,000 (of which £1,339,471 has been issued), and to offer it in the first instance to the shareholders and Debenture stockholders, at par. The stock is a first charge on the entire undertaking, and is irredeemable except in the event of the Government acquiring the concern, when it can be redeemed at 103 per cent. The net revenue for the year to June 30 last is stated at £369,007, and the amount required for the annual interest on the issued stock (including the present amount) is £58,431. It is anticipated that the net revenue for the year ending 31st inst. will show a considerable increase over the above figures. The list closes Friday, 16th inst., at 4 o'clock.

NEW ST. HELENS AND DISTRICT TRAMWAYS CO. (LIMITED).—The list closed on Wednesday, inviting subscriptions to 16,000 Five per Cent. Cumulative Preference and 10,000 Ordinary shares of £5 each in this company, which has been formed to acquire the tramways owned by the St. Helens and District Tramways Co. (Limited). The lines are about 10 miles in length, and are leased from the St. Helens Corporation. Included in the assets is a new lease for 21 years from Oct, 1 last of the old lines and for additional lines to be constructed by the corporation, the whole to be worked by electricity, for which power they are now being equipped.

PRIMITIVA GAS CO.—This Argentina concern, which has a capital of $4,000,000 in paper currency, and a debenture issue of £200,000, is about to be formed into an English company, with a capital of £800,000 in Six per Cent. Cumulative Preference shares, and there will be £400,000 Four per Cent. Debentures to replace the present Five per Cent. issue. The idea is, with the increased capital, to go more largely into electric lighting business, and to introduce the most modern appliances for heating and cooking by gas, as gas is replaced by electricity for lighting and power.

SMITHFIELD MARKETS ELECTRIC SUPPLY CO. (LIMITED).—The Four per Cent. Debenture Stock and Ordinary share transfer registers of this company are closed from Dec. 10 to 23 inclusive.

STOCK EXCHANGE NOTICE.—The Stock Exchange committee has ordered the further issue of £414,526 Sterling Four per Cent. 500-Year Debenture stock of the Commercial Cable Co. to be quoted in the official list.

SULPHIDE CORPORATION (ASHCROFT'S PROCESS) (LIMITED).—At a meeting of the shareholders of this company on Monday, under the presidency of the Earl of Kintore, the directors explained their reasons for discarding the Ashcroft process of electrolytic treatment of ores. A good deal of dirty linen was washed, and there is likely to be some lively proceedings before the subject is closed. Meanwhile, circulars of a more or less vituperative character are circulating. It is proposed to eliminate the words "Ashcroft's Process" from the title and to reduce the capital of the Company.

WESTERN AND BRAZILIAN TELEGRAPH CO. (LIMITED).—This company's traffic receipts for the week ended Dec. 2 (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Co., Limited) were £3,159.

WEST INDIA AND PANAMA TELEGRAPH CO. (LIMITED).—The estimated amount of the traffic receipts of this company for the half-month ended Nov. 30 is £2,839, against £2,061 in the corresponding period of 1897.

NOTES.

There was a record attendance at the meeting of the Institution of Electrical Engineers on Thursday last week, to hear Dr. Lodge's Paper on "Wireless Telegraphy," the large hall at 25, George-street, being so crowded that there were not seats for all, although as many as chairs could be found for were accommodated at the Council table, irrespective of rank. As we are unable to publish more than the preliminary portion of the Paper this week, we will not anticipate the second portion by describing the experiments with which Dr. Lodge delighted his audience. It will be sufficient for the present to say that, in spite of the alternating current at his disposal in the lecture-room being unsuitable for the purpose, the lecturer's practical demonstration of the principle of his magnifying telephones was as successful as his theoretical one. We look forward to a most interesting discussion next Thursday. In addition to Mr. Evershed's Paper, and some promised experiments by Mr. Preece and Prof. Fleming, we shall expect Mr. Whitehead (who was present at the reading of the Paper) to make a spirited defence of his own mathematical treatment of the screening effect of sea water. Those interested in this part of the subject will find the official abstract of Mr. Whitehead's Physical Society Paper, and of the discussion thereon, in *The Electrician*, Vol. XXXIX., p. 288.

Dr. Lodge referred to three chief methods of electric space telegraphy. He was probably aware of some experiments, recently made with ultra-violet light by Dr. Zickler in Brünn, but perhaps did not think them of sufficient importance to mention. On the same day as Prof. Lodge's demonstration before the Institution of Electrical Engineers an account of some further experiments by Prof. Zickler appeared in the *Elektrotechnische Zeitschrift*. We give an abstract of the article in another column, and it will be seen that he has now succeeded in overcoming distances of nearly a mile with comparatively simple apparatus. As we remarked on the publication of Prof. Zickler's first series of tests, the method may prove of practical value for signalling from lighthouses and lightships already equipped with electrical projectors.

The remarks in our last issue as to the harm caused by the non-delivery of plant in certain central stations have given rise to considerable comment and discussion, and in order that both sides of the question may be heard we have no hesitation in publishing in another column a communication written from the contractor's standpoint. Manufacturers have undoubtedly many difficulties to contend with in being obliged to depart from standard designs to the extent often required of them, and in being under the obligation to complete such special plant in an extremely short time. Of course, we should refuse to entertain any insinuation to the effect that such obligations are accepted without a reasonable conviction that they will be fulfilled. When, however, contractors are prevented by outside circumstances (as, for instance, strikes) from delivering the plant within the time specified, they should refrain from fixing any new time-limit unless they are absolutely certain of being able to keep within it. It is true that the uncertainty as to whether other tenders out for consideration will be accepted or not renders difficult an estimate of the time required for the completion of any particular contract, but it must be remembered that if such estimates are made on the basis of the usual number of hours worked *per diem*, unforeseen contingencies can usually be met by overtime and night-shifts.

When many causes contribute to an unwelcome result, there is generally great difficulty in apportioning the blame and in differentiating between the primary and secondary causes. In the particular case in point, the resident engineer places the blame on the contractor, and the contractor retaliates by censuring the consulting engineer, the resident engineer, or a sub-contractor. We have already insisted on the extreme importance of caution on the part of managers of central stations in adding new connections to their mains before they

Digitized by Google

are absolutely certain that they can be efficiently supplied during the period of heaviest load. So far as fogs and the shortness of days in winter are concerned, no alteration can be made to existing conditions, and in consequence it behoves the contractor and the resident engineer to work together to remedy the present condition of affairs and prevent its recurrence. The harm done to electric lighting by the recent inefficient supply is by no means imaginary, and it must not be allowed to extend further.

In reference to this subject, Mr. F. A. Newington, the resident engineer at Edinburgh, informs us that the deficiency had already been made good before the appearance of the Notes in our last issue. The serious difficulties under which the station was working have been overcome after much exertion, and since November 25th current has been supplied at the normal voltage, although the load is considerably increased.

If, however, the electric light in Edinburgh has resumed its normal brilliancy, those of our readers working in the English metropolis know to their cost that the voltage in this city has recently not been up to the mark. The reason given for this is again dilatoriness on the part of the contractors. Five new boilers have recently been erected, two of which have been in use for some time, and a third was to be put in operation on Wednesday evening. There has been considerable delay in the delivery of the steam pipes for these, and although they have been on order since last August, two boilers are ready bricked up, and still waiting to be connected. A sufficient number of alternators is running, but the difficulty is to get an adequate supply of steam at full load.

We report in another part of this issue the proceedings of the Court of Common Council on the presentation of a petition from the Charing Cross and Strand Electricity Supply Corporation, signed by 5,000 ratepayers, praying the City authorities to give their consent to that Corporation being granted a Provisional Order by the Board of Trade. The Charing Cross and Strand Corporation are to be admired for their persistency; but, so far as the Corporation is concerned, only one answer can be given to them and to the other companies who have begged for consent. Although not brought out in the Savory libel suit, the conclusion of which is given in another column, it is a fact that, by their agreement with the predecessors of the City of London Electric Lighting Co., the City authorities are precluded from concurring in any other company's application for a Provisional Order until the year 1911, when the contract for private lighting expires. After that time, the Corporation may itself enter into competition or give its consent to the application of other companies, the City of London Company retaining its Provisional Order for the usual term of 42 years. The report of an important meeting of the Commissioners of Sewers, at which one of the contracts with the Brush Company was considered, and the recommendations of the Streets Committee agreed to, will be found in Vol. XXIV. of *The Electrician*, p. 528, but unfortunately all the meetings could not be reported at the time owing to the Commissioners' occasional habit of discussing the electric lighting question with closed doors. The argument advanced during debate, that, in view of the evidence in the recent suit, the agreement is null and void, does not do credit originator.

In a Paper on "Meters and Systems of Charging for Electrical Energy," recently read before the Institution of Engineers and Shipbuilders in Scotland, by Mr. William Arnot, the author expresses the opinion that "a consumer could refuse to pay a disputed account that was not rendered from a meter duly certified by an electrical inspector." Although Mr. Arnot prefaces this opinion by a statement that he does not profess to be a lawyer; yet, coming from one who has had special opportunities in connection with the important office he has held of accurately informing himself on this subject, it naturally calls for some attention.

For a good many years after the issue of the first Provisional Orders, with the single exception of the Shallenberger meter for alternating currents, certified in October, 1891, for limited use by two companies in London, there was no certified meter in existence. It was not until October, 1896, when the Ferranti and Hookham meters were approved by the Board of Trade, that any meters were generally available to meet the requirements relating to certified meters stated in Provisional Orders. No alteration was made in the form of Provisional Orders consequent upon the approval of these meters, and, unless Mr. Arnot contends that the mere act of approval altered the law, he must be prepared to maintain that down to 1896 no consumer need have paid anything for the current supplied to him. He has evidently overlooked the fact that the clause he quotes requiring the supply to be ascertained by a certified meter contains the qualifying words, "except as otherwise agreed between the consumer and the undertakers." He also appears to ignore another fact, namely, that the choice of a meter is a consumer's matter. The consumer may either fix his own meter, or call upon the undertaker to supply one at his expense. If he takes neither of these courses, but accepts an uncertified meter, the inference must be that he has agreed to pay for the supply upon this basis.

What seemed at first sight to be anomalous when these Provisional Orders came out was that apparently the consumer might at any time have called upon the supply company to provide him with a certified meter. The position at the present time seems to be just the same, except that if the consumer thinks it worth while to demand a certified meter the Undertaker must supply it, which is rendered more easy by the addition in July last of the Aron meter to the certified list; but so long as he is content to go on with whatever meter has been supplied to him, the consumer must be assumed to have agreed to accept its records, subject, of course, to verification in case of dispute.

Personal.—The Shah of Persia has conferred the Second Class of the Order of the Lion and the Sun upon Mr. T. W. Stratford-Andrews, a Director of the Indo-European Telegraph Co.

Cable Interruptions and Repairs.—

	Date of Interruption	Date of Repair.
St. Louis and Noronha	Oct. 17, 1898 ...	Dec. 12, 1898.
Para—Maranham	Nov. 15, 1898 ...	—

International Telephony.—Frankfort, Brussels, Antwerp Liège and Verviers are now connected telephonically, and another international line has been opened between Frankfort and Basle.

Personal.—The Marquis of Tweeddale attended at Windsor Castle last week, when Her Majesty conferred on him the honour of Knighthood and invested him with the Insignia of the Order of the Thistle.

Long-Distance Telephony.—A long-distance telephone line, said to be the longest in the world, has just been established between Bar Harbour, Me., and Austin, Tex. It is 2,600 miles long and will soon be open to the public. It will connect New York, Washington and all the larger eastern cities of the United States.

Central Technical College.—The following is the list of scholarships awarded in connection with the session 1898-99 of the college:—Clothworkers' scholarship, £60 a year, to A. J. Cook; Mitchell scholarship, £50 a year, to R. H. Collins; John Samuel scholarship, £30 and free education, to F. C. Hounsfield; Institute's three studentships, to R. H. Buckie, A. W. Harrold and W. H. P. Brounger.

The Northampton Institute.—The members and students of this Institute held their first annual conversazione on Friday evening last, when the prizes and certificates were distributed by the chairman of the Governing Body. An extensive programme had been arranged, and among the lectures given was one by Dr. Mullineux Walmsley on "Wireless Telegraphy," and another by Mr. C. V. Drysdale on "Colour Photography." There were also the usual demonstrations in the various laboratories and workshops.

An Automatic Telephone Exchange for Glasgow.—We hear that a contract is being entered into for the erection of an automatic telephone exchange for 25 instruments in the municipal buildings at Glasgow. This is being done as an experiment, and we hope that a full account of the cost of erection and maintenance will, in due course, be published, so that a comparison can be established with the cost of a manual exchange. The results of the test, whatever they may be, will not be applicable to the problem of a 5,000-subscriber exchange.

The Royal Society.—Among the Papers down for reading yesterday were the following:—(1) "Application of Liquid Hydrogen to the Production of High Vacua and their Spectroscopic Examination." (2) "The Boiling Point of Liquid Hydrogen under Reduced Pressure," by Prof. Dewar, F.R.S.; "Ionic Velocities," by Prof. O. Masson; "Note on the Densities of Atmospheric Nitrogen, Pure Nitrogen and Argon," by Prof. Ramsey, F.R.S.; "The Preparation and Some of the Properties of Pure Argon," by Prof. Ramsey, F.R.S., and Dr. Travers; "The Action of Magnetised Electrodes upon Electrical Discharge Phenomena in Rarefied Gases" (preliminary note), by C. E. S. Phillips.

The "Financial News" on Telephony.—The *Financial News* of Dec. 12 contains a well-written description of the "Avenue" exchange of the National Telephone Co. Our contemporary had, in a previous issue, reviewed the company's service in a critical spirit and offered suggestions for its improvement. The National Telephone Co.'s good-humoured reply was an invitation to visit an exchange and view the system in operation, with the result that a readable account of the visit has appeared in the columns of the *Financial News*. On the other hand, although our financial contemporary has now no doubt explained to the officials in person its proposals for bettering the service, no marked improvement has since been noticeable.

Patent Amendments.—Application has been made to amend patents Nos. 8,607 of 1894 and 23,239 of 1897. Both patents relate to forms of automatic telephone exchanges, the former having been communicated from Chicago by A. E. Keith and the latter by the Strowger Automatic Telephone Exchange. Particulars of the amendments desired will be found in the *Patent Office Journal* of December 7th, and notices of opposition must be lodged by January 7, 1899. The reason given for the desired amendment is that the patentee is advised that some of the claims as originally drafted are capable of being interpreted too widely, and that he desires to restrict them to the invention described.

Society of Engineers.—The forty-fifth annual general meeting of this society was held on December 12th, at 17, Victoria-street, Westminster, S.W., for the election of the Council and the transaction of other business. The chair was occupied by Mr. Worby Beaumont, president. Mr. John Corry Fell was elected as president and Mr. George Burt as hon. sec. and treasurer for 1899. It was announced that owing to pressure of private business Mr. Pryce Cuxson had been compelled to resign the secretaryship of the society. Mr. Perry F. Nursey was appointed to fill the vacancy, and will take office on January 1st next. The following were elected honorary members of the society:—Sir J. Wolfe Barry, Prof. A. B. W. Kennedy, Mr. W. H. Preece, and Mr. Alexander Siemens.

Wiring Rules and Officialism in Germany.—As we mentioned in our issue of November 4th, the safety regulations issued by the Verband Deutscher Elektrotechniker have been officially recognised by the German Government. The result of this recognition was that they were circulated to the heads of the police departments of the various government districts to serve as a technical guide to them. These officials seem to be of opinion that the regulations are to be retrospective, and have already in one case forced the owner of an installation to execute extensive alterations in it, although it had been running without a mishap for six years, and although experts, whose opinions were taken, declared it to be free from any danger of fire. The matter has been brought to the attention of the Verband. As is rightly pointed out by the *Elektrotechnische Zeitschrift*, if the regulations are to be retrospective, thousands of installations, which were in existence before the appearance of these rules, will have to be entirely remodelled.

A New Belt-Driven Arc-Lighting Plant.—The plant recently installed by the municipal authority of Chicago for the arc-lighting of the northern and north-western districts of that city is a fine example of the survival of belt-driven plant in the United States. In this case, however, the particular method of driving used has several points in its favour. The nightly load on the station is now 866 arcs of 2,000 nominal candle-power, burning from dusk until daylight. The following particulars are from the *Western Electrician*:—The building is of brick, and there is a brick partition wall between the two rooms. The floors are of concrete. The stack is also of brick, 100ft. high and octagonal in shape. There are four tubular boilers of 100 H.P. each, equipped with Roney automatic stokers, one 500 H P. water-tube boiler and two 1,000 H.P. siphon condensers. Soft coal costing $2.02 a ton is burned, and the feed water is taken from the city mains. In the engine room there are two vertical compound condensing engines, rated at 600 H.P. each, which drive directly on a countershaft extending the length of the room, and the dynamos are belted to this shaft on each side. The shaft is provided with three friction clutches—one at each engine and one in the middle. Thus either engine may drive its adjacent half of the shaft or the whole line. Five of the dynamos are 150-lighters, made by the Western Electric Co., and the other three are Brush machines of 100 lights capacity each. The dynamo leads to the switchboard are laid in iron pipe under the floor, and all the outgoing connections from the board are underground. The switchboard is of white marble, with Western Electric instruments and plug switches. It is arranged for 10 dynamos and 10 circuits, to provide for extension. The new machinery in the plant cost about $37,000, and Mr. E. B. Ellicott, the city electrician, who laid it out, says that the cost of labour for running the station and trimming the lamps is $1,083 a month. The lamps are placed on the regulation side-arm poles adopted by the city, and have single carbons 14in. long and §in. in diameter. A force of 10 trimmers is employed.

Interruption to Supply at Cardiff.—At about 5:45 p.m., on Tuesday, the 6th inst., the supply at Cardiff was interrupted, and although the failure only lasted for about five minutes, it affected the whole of the system. There were running on the mains at the time a 300 kilowatt Ferranti flywheel alternator and two 40 kilowatt Paxman-Siemens sets. Some water lying in the receiver of the Ferranti plant was carried into the low-pressure cylinder, where, the clearance being only about 3 per cent., it produced a loud report, and the men in charge thinking something had been carried away, shut off steam and ran up the two spare 180 kilowatt sets immediately. There was nothing the matter with the Ferranti plant except that the trap on the receiver did not appear to have been working freely at the time.

Recently Expired Patents.—During the month of November three patents of considerable interest to electrical engineers have expired. The first is No. 14,723, taken out by the Hon. C. A. Parsons on November 7, 1884. It describes a special arrangement of the armature of an electric generator, a form of commutator, and also a method of electrical governing. The second is No. 14,954, of 1884, in which Mr. James Radcliffe describes a simple clip attachment to the handle of a "single needle block" railway signalling instrument, by means of which the handle is locked in the vertical as well as in the diagonal positions, and the unlocking of the handle is facilitated. Finally, No. 15,648, of 1884, granted to William Mather, John Hopkinson and Edward Hopkinson for "Improvements in dynamo-electric machines," illustrates types of single and double magnetic circuit bi-polar machines, and claims a simple method of letting the wrought-iron poles of the field magnets into the cast-iron pole-pieces, and the use of polar extensions of small area.

Electrical Advances in Japan.—The second electric railway undertaking in Japan is the Hoshu electric railway, which will run from Beppu to Oita, in Kyushu. Work was suspended for a while owing to financial difficulties, but these have now been overcome and the construction is steadily advancing. The contract for all materials was let to the Saiga Electric Co. of Kyoto, which Company in turn ordered the following pieces of main apparatus:—Two Lancashire-type boilers of 160 H.P. each (made in Japan); one 160 H.P. McIntosh and Seymour high-speed engine; one six-pole 110 kilowatt General Electric railway generator; 10 No. 21 Brill trucks and 20 25 H.P. railway motors. The engineers in charge of the work are Mr. H. Maki and T. Saiga, president of the Saiga Electric Co. A striking example of modern industrial processes surrounded by the quaint beauties of old Japan is the case of the tobacco factory of the Murai Brothers Co., in Kyoto. In this factory the electric distribution of power is used, the amount being 200 H.P., and upon its tower has recently been placed a large searchlight. The *Electrial World's* Japanese correspondent adds the information that the present name for the searchlight in Japanese is "tan-kai-to," which means the lamp which shines over the sea in the night, this form of apparatus having been first used in the navy, but hereafter, on account of its adoption on land, the name will probably be changed.

A New Source of Carbon for Carbide Furnaces.—The Ottawa correspondent of the New York *Electrical World* states that Prof. V. L. Emerson's invention for the conversion of sawdust and saw-mill refuse into commercial products was recently tested before a large gathering of the prominent lumbermen and citizens of Ottawa, among whom were several members of the Dominion Government. The machine gets its fuel from the gas obtained from the sawdust, so that the process is a continuous one. It runs automatically. First, the sawdust goes through a drying process by having all the excess of heat contained in the burnt gases forced through the sawdust in a drying kiln. Then this sawdust is carried by an elevator to the top of the retort, and by means of an automatic feed is supplied to the machine as required. The retort is an upright iron cylinder, between 15ft. and 20ft. high and about 3ft. in diameter, surrounded by brickwork. Within the retort is a series of hoods on a central hollow revolving shaft, which has perforations under the hoods. The various gaseous products escape through the lower end of the retort, where the liquid products are condensed and separated, emerging through two outlets. At one outlet passes off a wood creosote product, which can be utilised for a variety of purposes, and from the other crude pyroligneous acid, from which can be prepared wood alcohol, acetic acid and various other products. The gases pass through a purifying process, and after being highly heated are forced through the sawdust as it passes down the retort. The excess of gases passes into the furnace, supplying heat, which is practically sufficient to carbonise the sawdust in the retort. The carbon prepared from the sawdust passes out through an opening for the purpose at the lower end of the retort. The remaining product is a pure form of carbon, which, it is claimed, makes especially pure acetylene gas if used in carbide furnaces.

Röntgen Society.—The meeting of the Röntgen Society, held on Tuesday, Dec. 6th, at the Medical Society's rooms in Cavendish-square, was wholly devoted to discussing the important question of "Dermatites in Relation to X-ray Work." Two short Papers were contributed on this subject by Dr. Walsh and Mr. Payne, and the discussion centred itself mostly around certain points raised by the writers. It will be remembered, that, some time ago, the Röntgen Society issued a number of circulars to its members and others interested, with a view to obtaining in a tabulated form any accounts of authentic cases of dermatites which had been produced by the "rays," and at the meeting, the results, so far obtained by this means were laid before the members. The general conclusions arrived at were:—(*a*) that highly exhausted focus tubes are less liable to produce X-ray burning than are "soft" tubes; (*b*) that the ill-effects of the rays are prevented by a layer of clothing; (*c*) that the actual cause of the burning (so-called) is still uncertain and may be due to either the heat emitted by the tube when in action, the cathode rays, the X rays, or by the brush discharges taking place at the terminals of the focus tube. Dr. Holland, of Liverpool, reported some very interesting experiments in which certain troublesome ulcerous conditions had been apparently completely cured by the application of the X rays to the affected area. There is evidently a great deal yet to be done in connection with this question and the efforts on the part of the Röntgen Society will, it is hoped, in the end throw some further light upon the problem. What seems to be most needed is a really properly carried out experimental investigation into the whole subject—a work which might well be undertaken by a committee composed of medical and physical experts, and nominated very appropriately by the Röntgen Society itself.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-day) FRIDAY, December 16th.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS.

7:40 p.m. General Meeting in the Lecture Hall of the Sunderland Literary Society, Fawcett-street, Sunderland.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Students' Meeting. Paper to be read: "The Kentish Town Widening, Midland Railway," by Walter Daniel.

SATURDAY, December 17th.

INSTITUTION OF JUNIOR ENGINEERS.

11 a.m. Visit to Messrs. Yarrow's Works, Poplar.

TUESDAY, December 20th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be further discussed: "The Ventilation of Tunnels and Buildings," by Francis Fox. Paper to be read, time permitting: "High Speed Engines," by J. H. Dales.

9:15 p.m. Special General Meeting of Corporate Members to consider and, if approved, enact a Supplementary By-law.

WEDNESDAY, December 21st.

ROYAL METEOROLOGICAL SOCIETY.

7:30 p.m. Ordinary Meeting at the Institution of Civil Engineers, Great George-street, Westminster, S.W.

ROYAL MICROSCOPICAL SOCIETY.

7:30 p.m. Meeting at 20, Hanover-square, W.

THURSDAY, December 22nd.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting, when Mr. S. Evershed will read a Paper on "Telegraphy by Magnetic Induction." The discussion on Dr. Lodge's Paper ("Improvements in Magnetic Space Telegraphy") and on Mr. Evershed's Paper will be opened by Dr. Fleming and Mr. Preece, with experimental demonstrations.

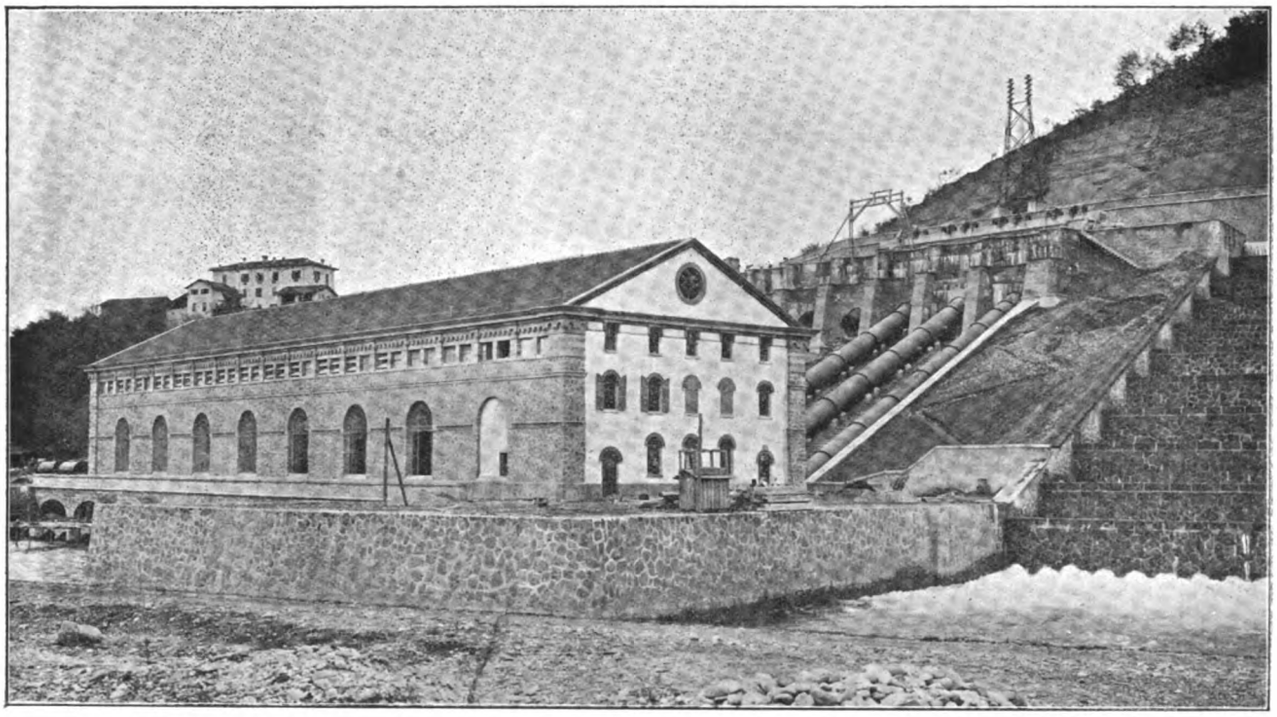
THE WATER-POWER INSTALLATION AT PADERNO.*

BY G. SEMENZA.

(TRANSLATED BY JOHN R. DICK, B.SC.)

The Paderno-Milan power transmission scheme was not the first of its kind, but it was a noteworthy event in the electrical world when the designs for it were got out, and the works actually commenced. There have been installations previously of greater power, but where the energy was transmitted over shorter distances, and there have been instances of the transmission of a few hundreds of horse-power, over considerably longer distances; but there has not been in existence up till now an installation in which 13,000 H.P. is transmitted to a distance of 20 miles. There has not existed, and perhaps there does not exist to-day, another installation so complex and so varied in its applications. Polyphase systems had not then received the sanction of practical experience, and extra high pressure were only in the experimental stage. Much uncertainty thus prevailed upon every point of the problem.



Paderno Generating Station.

For these reasons, the design of the plant at Paderno was a work of the greatest interest, and I hope to day to be able to give you a clear and complete idea of all the reasons which determined the choice of each of its components. Each point was thought out and chosen with that spirit of caution and striving after perfection, which we of the Old World—as opposed to American engineers—are accustomed to carry into new and daring enterprises. And here, I must mention, with gratitude and respect, the late Prof. Galileo Ferraris, who devoted so much care and thought to this enterprise. He was our adviser on the most difficult points, and in the day of success his name should not be forgotten.

As regards the hydraulic portion of the installation the technical journals have already published full partrculars. Still, I think it will be useful to give a short *rèsumé* of the general arrangement of the works, which are of such importance in determining the success of the undertaking.

Several hundred yards down stream from the famous bridge of Paderno, there has existed for about two centuries the canal-regulator of the Naviglio of Paderno, the object of which was to create a navigable channel parallel to the rapids of the river Adda. This regulator was formed of a weir and a pair of large gates which regulated the admission of water to the canal. Advantage was taken of this existing work to facilitate the new; but in order to convey 10,000 gallons of water, neither the height of the weir nor the section of the canal was sufficient. Accordingly the weir had its upper part rebuilt from that point, and the channel was enlarged from 30ft. to 43ft., so as to be able to convey 10,000 gallons with a velocity of 4·5ft. per second. The length of this enlargement is 750 yards, that is to say, for the first section of the Naviglio and up to the point called Conchetta. At this point is the regulator of the new canal, a building which permits the passage of the water by means of seven openings furnished with sluice-gates operated by hand.

A few yards below this, the canal, leaving on the left the Naviglio which runs along the picturesque valley of the Adda, enters a tunnel of 115 yards long, from which it emerges into a deep trench 26ft. wide and 273 yards long. Then follows a second tunnel of 302 yards, a second trench of 385 yards, and finally the last and longest of the tunnels, which measures 1,100 yards. This makes altogether a length of 2,448 yards. The volume of water has a cross-section of 180 sq. ft., and for the delivery of 10,000 gallons the velocity is 8·9ft. per second. The last tunnel terminates at a point in the valley, where the banks, receding from each other, open out into a wide space, and where the configuration of the land lends itself admirably to the development of works for utilising the energy. An ample penstock collects the water which emerges from the tunnel, and allows the motion to be gradually reduced in order to pass under the sluice-gates and to enter the pipes with a velocity of about 3·3ft. per second. On the left of the penstock is the head of the weir, which has to be large enough to dispose of 11,440 gallons of water. It is formed of a flight of steps, 95ft. high and 98ft. wide. The mass of water which runs down it is thus divided and broken up, until the enormous energy it possesses is entirely spent.

The pipes which convey the water to the turbines are seven in number, and are of 6·9ft. diameter. They are made of riveted steel plates, whose thickness is 0·315in. to 0·472in. These pipes are laid to suit the natural slope of the ground, and are 215ft. long. At the top a sluice-gate, electrically

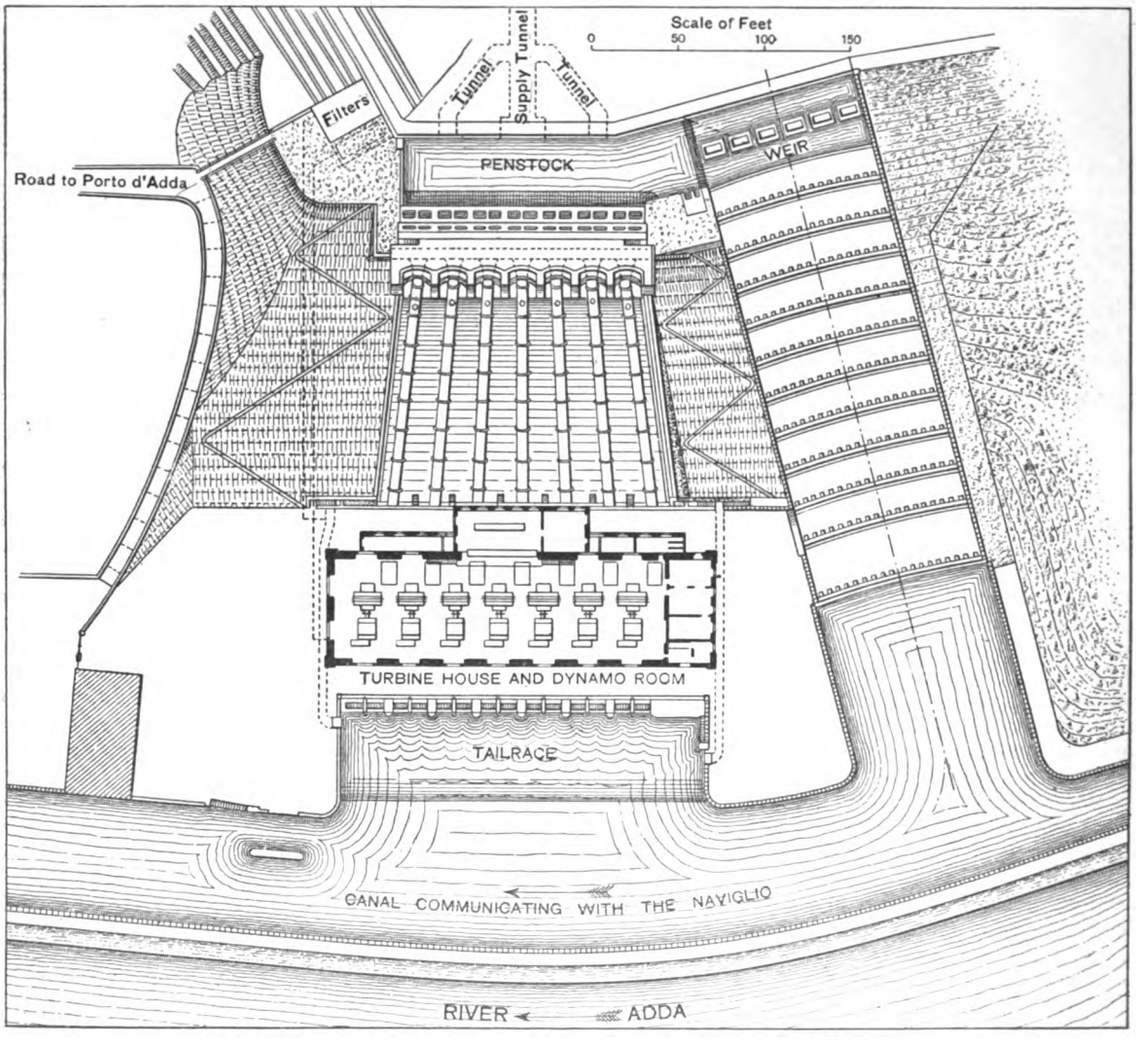
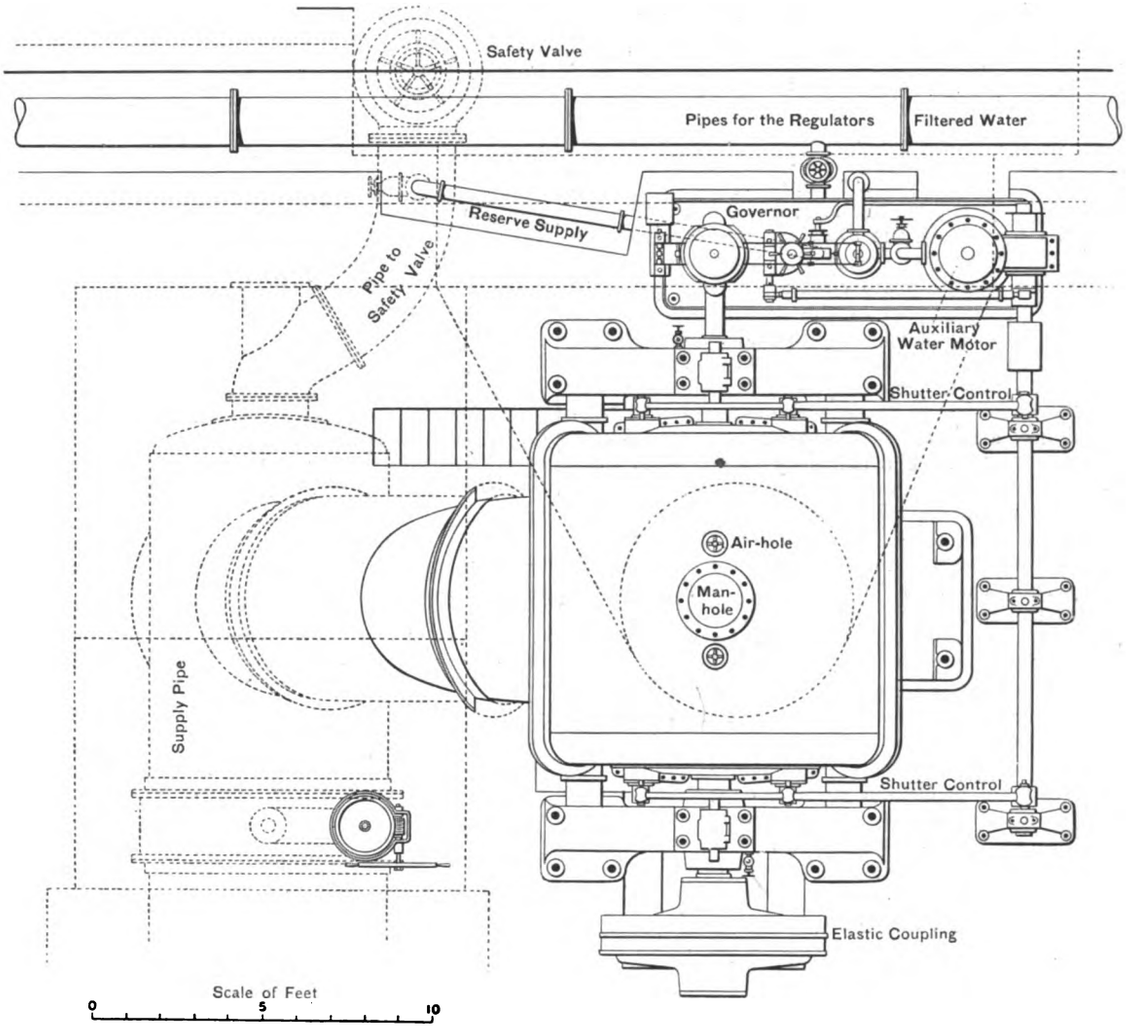
Transverse Section of Turbine House and Dynamo Room.



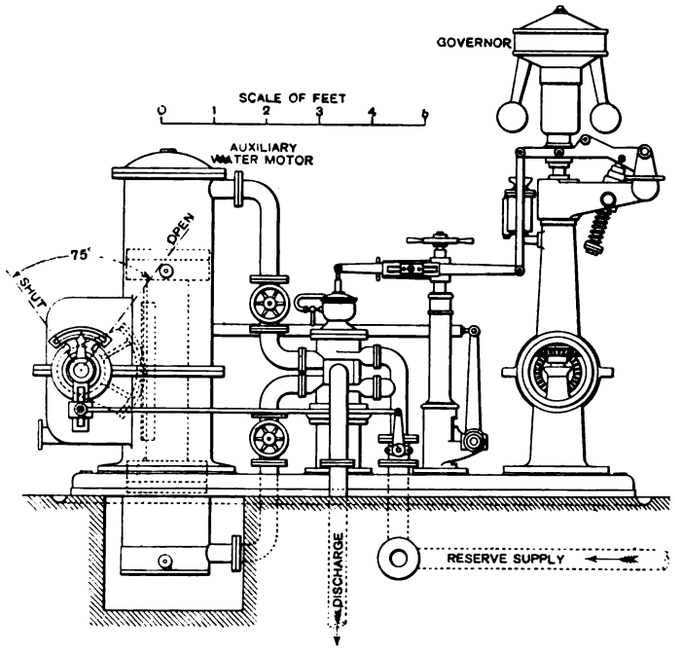
General Plan of the Buildings.

Digitized by Google

controlled, shuts off the admission, and at the bottom a butterfly valve prevents the flow of the water towards the turbine. From the turbine the discharge takes place into a wide tail-race, which does not communicate directly with the river, but with a canal which is a prolongation of the Naviglio. As the latter re-enters the river about 648 yards above the point where the discharge from the turbines reaches it, in times of drought this section of the river would be practically without water, and would not permit of navigation. The prolongation of the canal of the Naviglio enters the Adda about 438 yards below the point of discharge at a bend of the river very opportunely chosen, and thus returns to the Adda the water which, instead of uselessly consuming its energy in erosive action on the rocks and in heat, is transformed into another form available for commercial purposes.



Plan of one of the Turbines.



Auxiliary Regulating Motors, Ganz type.

The delivery in times of drought is 10,000 gallons. The net fall in the dry season is 94·5ft. In times of flood this is reduced to 81·6ft. It is therefore necessary in order to have the same average power, whatever the height of the water, to increase the delivery in proportion as the fall diminishes, and an easy calculation shows that in times of flood this will have to be 11,500 gallons. All the canals, accessory works, turbines and tail races are designed for this maximum delivery. The power, represented by 10,000 gallons of water per second with a fall of 94·5ft., is to 17,300 H.P., which, with a turbine efficiency of 75 per cent., gives nearly 13,000 H.P. actual output. In dividing this power into generating units, it must be remembered on the one hand that the efficiency of each machine increases with the increase of power, and, on the other hand, that the number of groups should be such that the breaking down of one should not, in practice, be a serious inconvenience. Accordingly it was divided into six units of 2,160 H.P. each, while a seventh was added as reserve.

Considering the great variability in the level of the tail-race, it was necessary to have recourse to suction turbines. The part of the fall which acts by pressure is 75ft., and that by suction is 19·5ft. in times of greatest drought, and 6·6ft. in times of flood. With such a division of the fall it is possible to keep the floor of the dynamo room above the level of the highest flood, which is a matter of great importance.

The manufacture of these turbines, which (with the exception of those of Niagara) are the most powerful made up till now, was entrusted to the firm of Riva, Monneret and Co., of Milan, after a competition in which the best European firms took part.

The turbine is of the inward-flow type with twin wheels. The blades have a curved surface of a somewhat complex shape. As has been said, it acts by suction, hence the wheels always work submerged. The water enters laterally into an annular casing, 10ft. diameter, made of steel plates, which encloses the arrangement of distributors and wheels, and it leaves by the suction pipe fixed in the concrete of the foundation. As can be seen from the drawing, the bearings are entirely outside the water chamber, so that they may be easily examined when the machines are running. The regulating shutter is a ring forming part of the distributor; when a rotatory motion is communicated to it, the guide blades open or close the admission ports. With this system, all the ports of both wheels are shut simultaneously, and the shock on the shaft is practically nullified. These turbines make 180 revolutions per minute, and each has a maximum capacity of 1,916 gallons per second. The efficiency guaranteed by the maker is 78 per cent. for a given fall and volume of water, hence, in this 22 per cent. loss, is comprised that due to friction in the pipes and bends. The whole of the turbine is easily taken apart, a most valuable feature in an installation whose working should never be interrupted. The governor, which regulates the rotation of the shutter, is of the Ganz type, the variation of speed allowed being 2 per cent. during normal running, and 4 per cent. for 25 per cent. variations of load. In order to facilitate running in parallel, the Siemens system for varying the speed of the governors will be employed. This simply consists of a small motor worked from the switchboard, which stretches or releases the spring opposed to the conical pendulum governor. By this means the switchboard attendant can adjust the speed of each turbine—or their load if running in parallel—by simply pressing a button. The turbine is connected to the alternator by means of an elastic coupling.

(*To be continued.*)

SUPERHEATED STEAM AND ITS APPLICATION ON STEAM ENGINES.*

BY PAUL SCHOU.

The subject I have the honour to lay before you to-night is scarcely new to you, England being the first country where experiments were made, as long as 40 years ago, to use superheated steam in steam engines. The economy obtained at that time was not very great, as only moderately superheated steam could be employed, owing to the difficulties in lubricating the working parts of the steam cylinders, which could not be overcome as the lubricants then used became useless when they came into contact with steam of a high temperature, consequently the steam engine did not work satisfactorily. It was, therefore, soon found that other means would have to be adopted to utilise the steam more economically—this was done by gradually increasing the steam pressure and expanding the steam in more than one cylinder. The economy far exceeded the results obtained by the first experiments with superheated steam. This latter process was, therefore, left alone for many years, and it is only lately that the question of using superheated steam has again come to the front, after it has been found impossible with a triple, or even quadruple engine, to gain any higher economy worth speaking of.

Before describing the application of superheated steam, allow me to explain the reason why we cannot, when using saturated steam, utilise the heat to greater advantage than we already do now. The reason cannot be found in the construction of the steam engine, which has been carried out to perfection, but it must be found in the nature of the saturated steam itself. The great drawback in using saturated steam as a driving power is, that its range of temperature is very limited. On the one side, to raise the temperature of steam we have a rapid increase of the steam pressure, and, on the other hand, we cannot lower the temperature of the steam below the temperature of the condenser. Quite apart, however, from these drawbacks, practice shows us that the heat cannot be transformed into work without great losses. These losses take place principally in the steam cylinder, a part of the steam being condensed when coming into contact with the cylinder walls. The lower the mean temperature of the cylinder walls and the temperature of the steam leaving the cylinder, on the one side, as against the temperature of the admission steam on the other side, the greater are the losses by initial condensation. The earlier the cut-off is, the more the losses increase, as the admission steam only heats a smaller part of the cylinder walls, that is, the mean temperature of the cylinder walls is lowered, consequently, a larger percentage of the steam is condensed during the expansion period.

Through this exchange of heat between the steam and the cylinder walls, twenty per cent. of the heat is lost without doing any work, even in the best existing engines, but this loss very often amounts to fifty per cent., and more in ordinary engines. To minimise these losses two methods have been employed, viz., the fixing of a steam jacket round the cylinder to raise the temperature of same, and expanding the steam in two or more cylinders, so as to reduce as much as possible the difference of temperature between the steam entering and leaving the cylinders.

A third method remains, viz., to superheat the steam by adding so many units of heat above those contained in saturated steam, so that (*a*) the ratio of sensible heat to total heat may be increased, and (*b*) considerable reduction of temperature may occur in the cylinder before reaching the point where condensation commences. The theoretical gain due to (*a*) is expressed by the formula

$$\frac{T_1 - T_2}{T_1}.$$

The gain due to (*b*) is no less important, though it cannot be so simply expressed.

Heat is transmitted from steam to water with such rapidity that the late Mr. P. W. Willans was disposed to attribute the phenomenon of initial condensation almost entirely to the presence of water; whether this theory be correct or not, the fact remains that the adoption of a high degree of superheat practically eliminates initial condensation. The exposed surfaces of iron remain and the steam is there as usual, but there is no water for the simple reason that the walls of the cylinder are maintained hotter than the saturation temperature of the steam in contact with them.

The practical effect of (*a*) and (*b*) taken together is as follows:—

A triple expansion engine, working with 180lbs. steam-preasure, may, under favourable conditions, produce one H.P. with 12½lbs. of steam. The same steam superheated 150 degrees Cent. will, in a compound engine, produce one H.P. with 8¾lbs. of steam; the actual saving in heat units is 22½ per cent. To go still one step further, it would be possible to get the same efficiency in a compound engine working with 11 atmospheres pressure, as in a quadruple expansion engine working with 25 atmospheres pressure. You will, therefore, see that if we could only do away with the initial condensation a double advantage would be gained. First, we could in most cases do away with triple expansion engines; and, second, could reduce the boiler pressure, which would lower the cost of same.

I will now proceed to explain the nature of superheated steam. Superheated steam is dry saturated steam, which has been heated to a higher temperature than that corresponding to its pressure. The higher the temperature of the steam, the more its condition can be compared with a permanent gas, and, therefore, it becomes a bad conductor of heat. If superheated steam is used in a steam cylinder it can be expanded to a certain point, according to the degree of superheat, before reaching the so-called saturation point. A certain part of the heat is naturally lost during the expansion period through the exchange of temperature between the steam and the cylinder walls, but this loss is small compared with the loss of the latent heat in the steam which takes place through initial condensation. Superheated steam has, however, another great advantage—viz., that its specific volume is greater than that of saturated steam of the same pressure. If you, therefore, have two cylinders of exactly the same size, both working with the same degree of expansion, the weight of steam will be less in the cylinder working with superheated steam. The volume increases in proportion to the superheat; in other words, the more you superheat the less steam is used per horse-power. If, therefore, a considerable economy has to be obtained, it can only be done by using highly superheated steam, but I am sorry to say that in this country, engineers do not seem yet to have grasped this fact. The general opinion seems to be that, if you only superheat the steam a few degrees you get all the economy worth having. One of the reasons may be that the superheaters which, up to now, have been in the market here, cannot work with highly superheated steam for any length of time.

Mr. Schmidt, of Cassel, was the first engineer to introduce a complete plant working with highly superheated steam. The task was a difficult one. Mr. Schmidt was working for fourteen years before he was able to construct a plant to withstand the most severe test. The result has been very striking indeed, and now over 200 complete plants are working satisfactorily in various parts of the

* Abstract of Paper read before the Northern Society of Electrical Engineers at Manchester, on Thursday, December 8th.

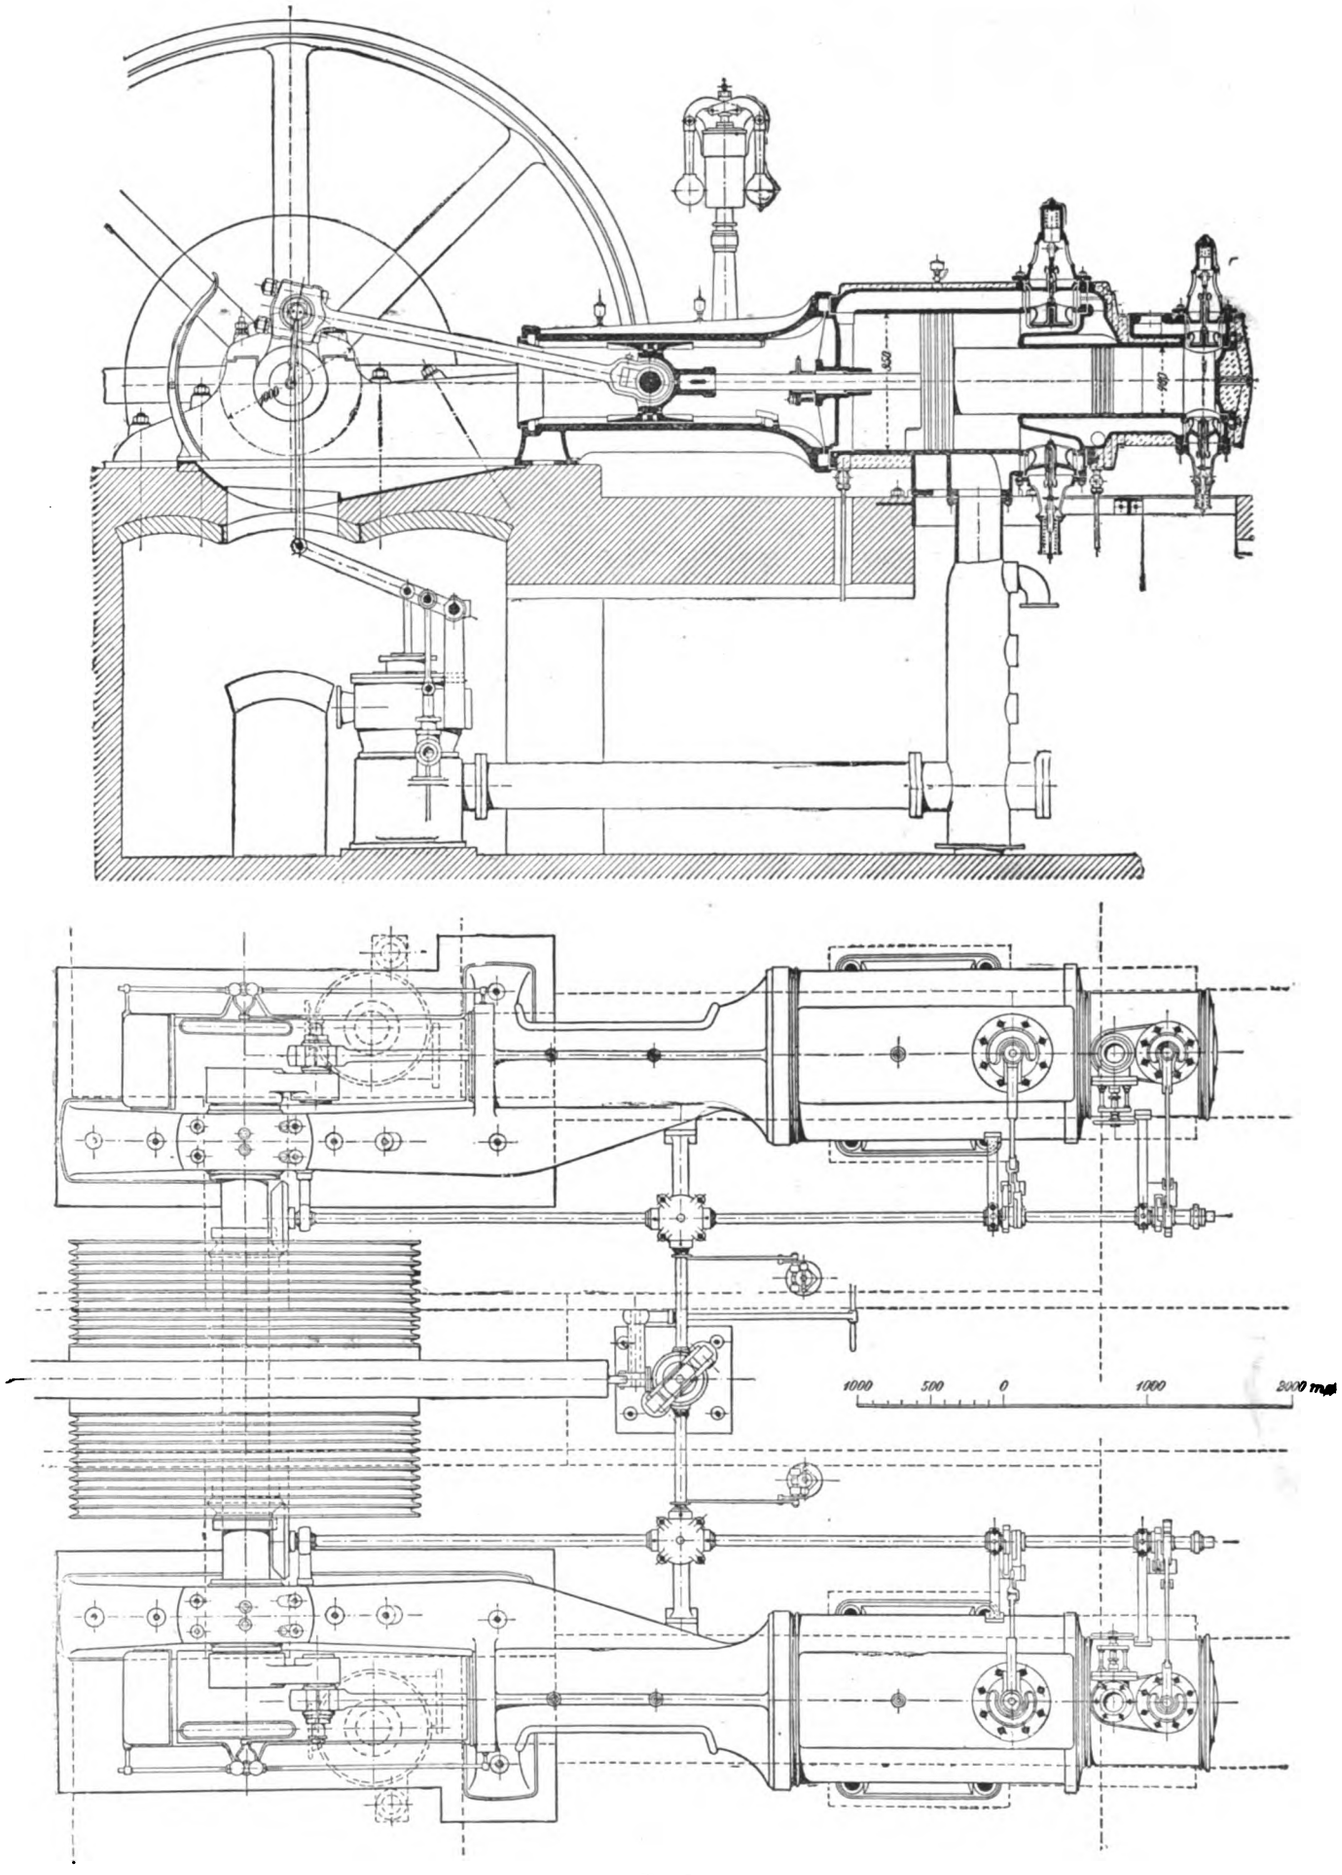

FIG. 1

Digitized by Google

world. That superheated steam can also be used for large plants may be gathered from the fact that a 750 H.P. compound engine plant has been running now for 3½ years, night and day continuously, without the slightest hitch. The engine is used for a mill, rolling fine steel sheets, and the power given off by the engine varies from 400 to 750 H.P. The economy has been remarkable, viz., only 8¾lbs. of steam being used per indicated horse-power per hour. The boilers are heated by producer gas, the consumption being equal to 1lb. of coal per indicated horse-power per hour. This result, without doubt, is the best ever obtained on any steam engine in the world. As a proof that this plant has been a success, the existing steam power will be replaced by a Schmidt plant of 4,000 H.P. The economy for smaller plants has also been very remarkable. The writer has made very careful tests on a 70 H.P. tandem compound engine, which is driving an ice factory in Ireland, and the steam consumption was 10·2lb. per indicated horse-power per hour, and the coal consumption 1·4lb. per indicated horse-power per hour.

The steam enters the high-pressure cylinder, forcing the piston forward; when the piston moves back the steam is led into the receiver. On the next forward stroke the steam passes from the receiver into the low-pressure cylinder. Although the high and low-pressure cylinders are single acting, the engine is, to a certain extent, double acting, through the novel arrangement of the receiver in which a certain part of the work is performed.

The construction of this engine adapts itself very well to working with steam at high temperatures, for the following reasons:—(1) the high-pressure cylinders require no steam jackets; (2) the heat taken up by the high-pressure cylinder walls, during the admission period is not lost, but serves to heat the receiver; (3) the low-pressure cylinder is heated by the receiver steam; (4) the high-pressure piston is cooled inside by the receiver steam; (5) there is but a single stuffing box, which is only in contact with the receiver steam. The lubrication, therefore, is as in an ordinary engine. At first sight, it may be said that this engine has one

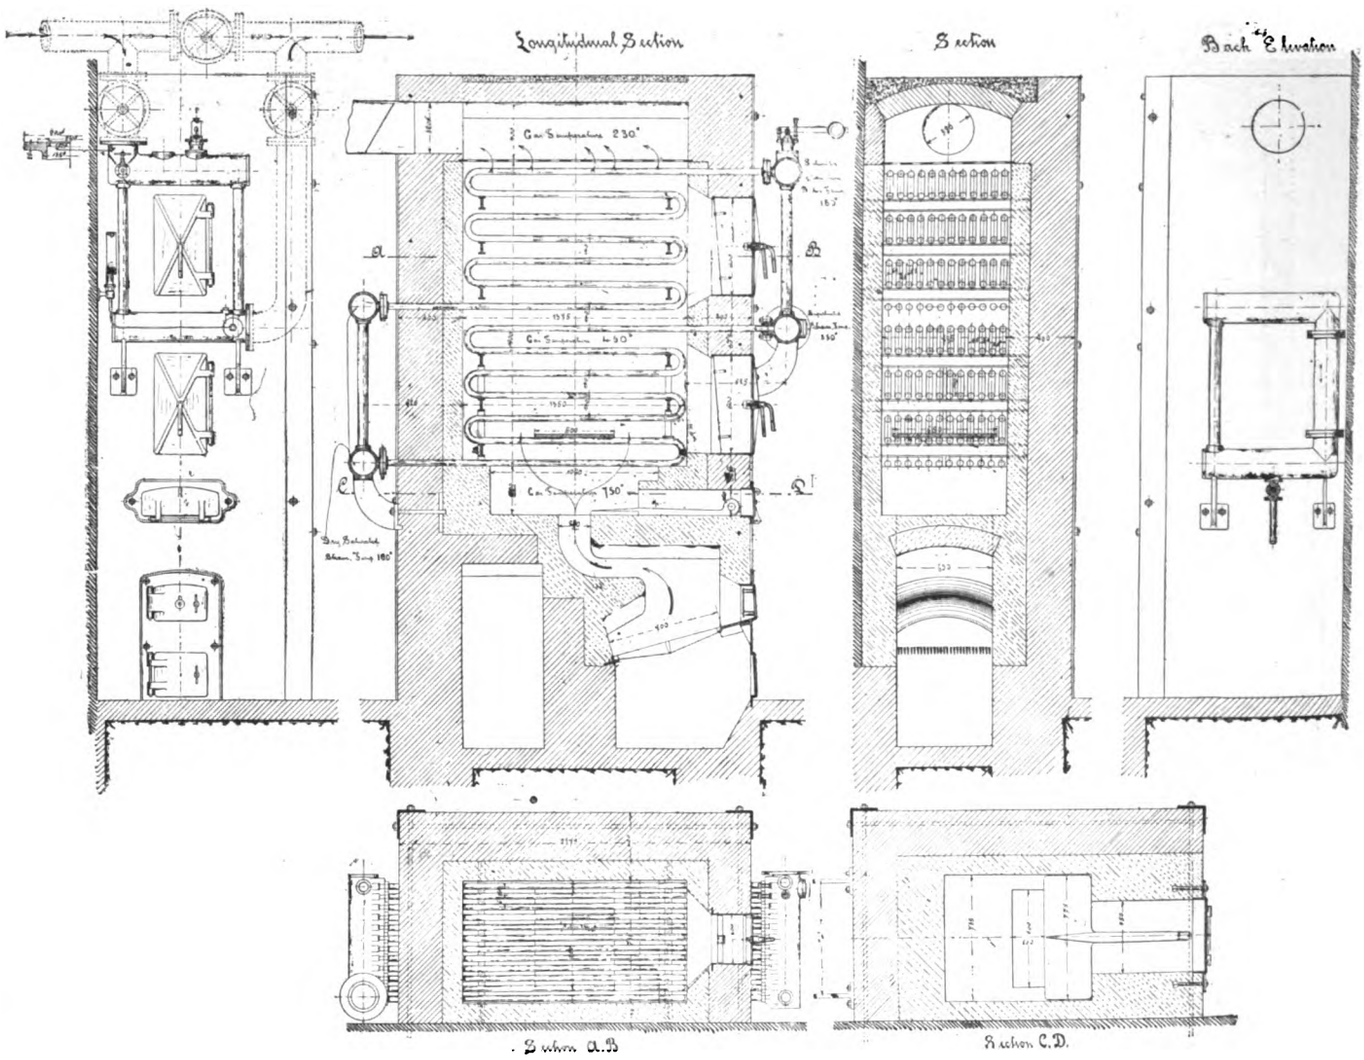

FIG. 2.

The difficulties which had to be overcome, before making it possible to construct plant to work with highly superheated steam, have been, first of all, to construct the superheater in such a way that the tubes in which the steam is superheated would withstand the high temperature of the gases; and secondly, the proper lubrication of the working parts of the steam engine. As, however, it is now possible to obtain a mineral oil with a flashing point of 380 to 400°C., the difficulties which were met with so many years ago have disappeared. Even, with this special oil, the best way of lubricating the gearing for admitting steam into the cylinders and the piston rings had to be devised.

Most of the steam engines, working with highly superheated steam, have been single acting, so as to prevent the piston rings coming into contact with the steam during the admission period. The most interesting type of this kind, and the one which has given the best result, is the Schmidt tandem compound engine, shown in Fig. 1. The pistons for the high and low-pressure cylinders are made in one piece: the front part of the cylinder forms the receiver, the ring-space A being the low-pressure cylinder. drawback, viz., that the high and low-pressure cylinders are only separated from each other so long as the piston rings in the high-pressure cylinder keep tight. The difference in pressure between the high and low-pressure cylinders is, however, not so great as to make it difficult to keep the piston rings tight, when one considers that when the steam is admitted to the high-pressure cylinder, the low-pressure cylinder is connected to the receiver and that there is only vacuum in the low-pressure cylinder when the high-pressure cylinder is connected to the receiver. Diagrams of this type are shown in Fig. 3.

There are various other arrangements in compound engines, viz., a single acting high-pressure cylinder, and a double-acting low pressure cylinder, but of course with all these types of engines, if adopted for very large powers, the cost is rather high on account of the superheated steam only working in a single-acting cylinder. Schmidt, therefore, has made experiments to use superheated steam in double acting engines, which, however, is only possible after introducing quite a new way of using the steam. This new idea consists in superheating the steam according to the

Digitized by Google

degree of expansion in the cylinder. This may be carried out in several ways, one being to connect two steam pipes to the cylinder, one coming from the superheater and the other direct from that part of the boiler where saturated steam is produced. The governor on such an engine has two duties to perform, viz., to regulate the degree of expansion and to regulate the temperature of the steam. To regulate the temperature a valve is fixed in the pipe containing the saturated steam, which is connected by levers to the governor. When working with an early cut off only superheated steam is admitted to the cylinder, and as the degree of expansion increases the governor opens the regulating valve, allowing a certain amount of saturated steam to mix with the superheated steam, lowering its temperature; by this arrangement any temperature required may be easily obtained.

The principal object of this idea is to make it possible to produce a low mean temperature of the cylinder walls, so that steam of high temperatures may be used with safety. In double-acting engines the idea to superheat according to the degree of expansion has been carried still further, by also superheating the steam in the receiver, between the high and low-pressure cylinders. A large plant is now working in Russia very satisfactorily, constructed on this principle, and, although no exact tests have been made, Mr. Schmidt expects the steam consumption to be only 8lbs. per indicated horse-power.

Having now described the steam engine, I will proceed to describe the superheater. The Schmidt superheater consists of a series of tubes, varying in diameter from 1in. up to 2in., according to the size of superheater, the coils being welded together in long lengths, so as to prevent any joint coming into contact with the flue gases. The coils are formed in either a spiral or zigzag shape, to suit existing circumstances. The superheaters may

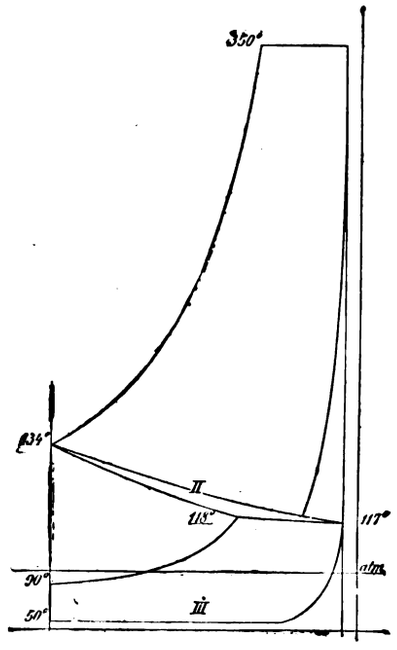

FIG. 3.

either be arranged in the flue behind the boiler, or altogether separate from the boiler plant, the latter type being fired direct by coal or gas; either kind of superheater may be attached to any existing boiler.

In the superheater arranged in the flue behind the boiler the steam travels through the superheater coils in the following way:—Suppose the gases from the boiler enter the superheater from the bottom, then the saturated steam from the boiler is led into the superheater through the top coil and travels through one-half of the coils in the opposite direction to the gases, and is then led to the bottom coil of the superheater, arriving there perfectly dry, but not superheated. The steam then travels in the same direction as the gases, being led off from the superheater at about the middle of the coils. By this arrangement, the coils, which are placed nearest to the gases having the highest temperatures, are cooled inside by the steam preventing the coils from becoming too highly heated. This, of course, is the only way to prevent deterioration for any length of time. Further, all the heat of the gases is utilised as economically as possible.

I should like, here, to say a few words about the economiser invented by Schmidt, which he arranges behind the superheater so as to still further reduce the temperature of the gases before entering the chimney. The principle of this economiser is to work with distilled water in the coils arranged in the flue and passing the distilled water through the feed-water heater. The advantage of this economiser is its great simplicity, it being possible to make the coils in long lengths, as no deposit takes place inside them and, therefore, no cleaning is required. Further, the feed-water being heated indirectly by the distilled water passing through the economiser, the temperature of the distilled water returned from the feed-water heater is sufficiently high that the vapour contained in the flue gases coming from the boiler does not condense when coming into contact with the economiser coils. The result is that the soot does not adhere to the coils and may be blown off with a small jet of steam in the course of a few minutes, say, every week or fortnight, according to the nature of the coal.

The direct fired superheater (Fig. 2) is constructed on the same principle; the gases entering the superheater from below, and travelling in an upward direction. This type of superheater is specially applicable to cases where a boiler plant already exists, the only alteration required being to lead the steam through the superheater, instead of direct from the boiler to the steam engine. Although extra coal is used for heating the steam, a total coal saving of 20 to 25 per cent., even on the best compound engine, can be obtained from adopting this kind of superheater.

Before concluding I may say, that especially for steam engines driving large electrical supply stations, there is a great future for the utilisation of superheated steam, as the heavy losses which now take place, on account of the steam engine, having during certain parts of the day to work with only half loads, can be prevented by adopting the Schmidt system, and I hope I have been able to show that the practical difficulties attached to this system have been overcome. In your own town, Manchester, there will shortly be laid down two boilers, both being connected with a Schmidt superheater—each plant being capable of producing 10,000lb. of steam per hour. The boilers will be heated by Mond's producer gas, and the steam will drive a 1,000 H.P. Raworth engine, to be used for electric power distribution.

DELAY IN THE DELIVERY OF PLANT.

The following communication appears to embody the manufacturers' point of view on the question of the non-delivery of electrical plant:—

It may be worth while to consider to what extent the present rapid development of electric lighting is due to the unceasing attention which manufacturers have for years past paid to the development of plant suitable to their customers' requirements. Most of the time, be it remembered, manufacturers have been struggling to keep their heads above water, with no inducement to extend their factories, they doing the work and the lighting companies making the money. Now, when success has crowned the efforts of manufacturers to perfect their designs, and electric lighting is, in consequence, progressing by leaps and bounds, they are further to be penalised for not having facilities to turn out the plant as rapidly as required.

It cannot be denied that in this country purchasers have little regard to the types of plant which can be most rapidly produced; each must have his own specification adhered to, and after months or years of dallying a specification is issued at the last moment. With little idea of what is reasonable in regard to time, the manufacturer is then expected to rush the plant through, regardless of obligations to other customers.

In tendering, manufacturers generally have the force of circumstances entirely against them; they cannot with any accuracy gauge the amount of work they will actually receive, and in fixing the time for delivery, they have to be guided more by the pressure put on them by the purchaser than by their own capacity for production, knowing that if they do not comply with the time prescribed by the specification, their tenders will not receive consideration. The result is that while each customer considers his interest paramount, the manufacturer has to distinguish between many customers, and, however much he is behind, he must deal with orders in rotation. He has, too, troubles with regard to the supply of material, especially at a time when all trades are so busy, and often he may have to wait for some time for a trifling item in order to complete an order, and although the delivery of the whole may depend upon a trifling part, he cannot bind the sub-contractor to any penalty on account of its small value. New types, also, often take longer to elaborate than

Digitized by Google

could be anticipated when the order was taken, and as almost every order involves some fresh departure it is not to be wondered at that delays occur. Let everyone consider the variety in output, speed, voltage, periodicity and design in all classes of dynamos or alternators, and the numerous types of transformers, boosters, balancing machines, &c., which now go to make up a central station, and he will gain a faint idea of the amount of labour and uncertainty which has, up to the present, beset the manufacturer on all sides, with so small a return.

ELECTRICITY WORKS ACCOUNTS.

Birmingham Electric Supply Co.

The first of our two analyses this week is that of the accounts of the fifth and sixth completed years of working of the Birmingham electricity supply undertaking.

The whole of the authorised share capital, which stands at £200,000, has been received on the issue of 40,000 £5 shares. A total of £219,077, representing £146 per kilowatt of plant capacity, has been expended on capital account, £35,250 having been expended during the year, included in which amount is the expenditure on works in connection with the new boilers and extensions at the Dale End station.

During 1897 an equivalent of 26,712 8 c.p. lamps was added to the mains, thus raising the total lamp connection at December 31 last to 78,464, showing an increase of nearly 52 per cent.

The corresponding increase in the output was over 56 per cent., being 1,183,539 units sold in 1897, as compared with 756,428 in 1896, and as a result the average revenue per unit has dropped from 5·67d. to 5·14d. Reductions in the management and property charges have had the effect of reducing the total costs per unit in spite of a slight rise in the works cost through the fuel and distribution items.

The net result of the year's working is an increased ratio of the costs to revenue and a working profit of £12,733, out of which £4,460 has been carried to the depreciation fund, and £120 paid as bank interest. A balance of £1,043 from 1896 has enabled a dividend to be paid of 5 per cent. on the Ordinary shares, leaving £989 to be carried forward.

At the close of 1895 the connection to the mains was an equivalent of 36,398 8 c.p. lamps, and the output for the year had been 490,000 units. The lamp additions to the mains since the end of 1897 brings the total equivalent lamp connection up to considerably over 81,000 8 c.p. lamps. In view of the continually increasing output and the large number of motors added to the circuit, extensive additions to the plant at the Water-street station are in progress.

The capital has been raised from £200,000 to £300,000 by the creation of 20,000 additional £5 shares.

Sheffield Electric Light and Power Company.

December 31, 1897, marked the end of the fourth complete financial year of working of the Sheffield undertaking. The steady and rapid progress which has characterised it has been well maintained during 1897, and very material economies also effected. The total capital received amounts to £112,975, £87,975 accruing from the issue of 14,000 £7 shares (on 10,000 of which only £6 per share has been called up), and £25,000 raised on 4½ per cent. Debentures. At December last the total capital expenditure stood at £123,023, representing £133 per kilowatt of plant capacity.

During the year 154 additional consumers, with an equivalent of 13,323 8 c.p. lamps, were connected to the mains, raising the total lamp connection to 55,988. The output for 1897 was 747,063 units sold, as compared with 483,427 units in 1896, an increase of nearly 55 per cent.

Consequent upon a reduction at the beginning of the year in the price charged per unit, the average price obtained has dropped from 6·2d. to 5·24d. Very material reductions in the costs have been made, generating costs having been reduced from 1·45d. to 0·98d. The actual fuel bill is, in spite of the increased output, less in 1897 than it was in the preceding year.

Management and property charges per unit have also been reduced—viz., from 0·6d. to 0·45d. The already low figure of 36 per cent., representing the ratio of costs to revenue, has been improved upon in 1897 by being reduced to 29·6 per cent. A working profit of £11,477, representing no less than 10·9 per cent. on the mean capital for the year, was made. Out of this, £1,209 was paid as interest on loans, and the balance, with £100 from 1896, permitted of a dividend of 12½ per cent. being paid on the Ordinary shares, leaving a balance to carry forward of £903. Nothing, however, appears to have been carried out of the nett revenue to any reserve fund, although the sinking and depreciation funds have both been augmented by addition voted from the premiums accruing from the issue of shares.

In 1893 the output was 131,752 units sold, and the revenue from supply was £3,556; in 1894 the output was 192,220 and the revenue £4,849, while in 1895 the revenue from supply was £6,935, with an output of 288,406 units sold. The total cost per unit was in 1893 5·14d., in 1894 3·8d., in 1895 3·6d., in 1896 2·23d., and in 1897 1·55d. On March 31 last the price charged for current for lighting was reduced from 5d. to 4d. per unit.

Further additions to the plant in the station are in progress.

The following is a list of electric supply works the accounts of which have been analysed, together with the dates on which statements and analyses of accounts have appeared:—

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal 1863—1878).

Published every Friday, Price Sixpence; Post Free, Sixpence Halfpenny

Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone: 949 Holborn. *Telegrams:* "Electrician Newspaper London."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "The Electrician," Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to "The Electrician" Printing and Publishing Company, Limited, and be crossed "Coutts and Co."

All Editorial letters to be addressed to The Editor.

All letters for insertion in "The Electrician," or containing questions, must be accompanied by the name and address of the writer as evidence of good faith. No notice whatever is taken of anonymous communications.

"The Electrician" is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices, as above.

New Volumes of "The Electrician" commence in April and October.

Subscription Rates.—The Rates for Subscriptions to "The Electrician" are as under:—

	Year	Half-Year	Quarter	
United Kingdom	26s. 6d.	13s. 6d.	7s. 6d.	Post free, payable in advance.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.	

"The Electrician" offers exceptional advantages to Advertisers. It has by far the largest circulation of any English Electrical paper, and circulates all over the World. *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

Trade Advertisements *intended for the current issue must reach the Office not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday. Wrapper Advertisements by Wednesday morning.*

Official Announcements, Auctions, *and* Small Advertisements *accepted up to 6 p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct o "The Electrician" Printing and Publishing Company, Limited. The well-known "Electrician" Series of Standard Electrical Works at present consists of—

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young, M.I.E.E. Price 10s. 6d., post free; abroad 11s.

THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By Messrs. H. K. C. Fisher and J. C. H. Darby. Price 6s. net; abroad, 6s. 3d.

BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH. Edited by C. E. S. Phillips. With an introduction on the history of Crookes Tube and Röntgen Ray work, and a chapter giving "Practical Hints," on the subject.

THE POTENTIOMETER AND ITS ADJUNCTS. By W. C. Fisher. Price 6s., post free.

LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS. By F. C. Raphael. Price 5s., post free.

MOTIVE POWER AND GEARING. By R. Tremlett Carter. Price 12s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson. Price 12s. 6d., post free.

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. Fleming, M.A. F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d., post free 13s. *Vol. II. is nearly ready.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. Fleming. VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. New Edition. Price 12s. 6d., post free. VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. 98 original Illustrations, price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. Snell. 10s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. George Gore. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. Weymouth. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By Gilbert S. Ram. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Gnipel and H. M. Kilgour. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d., post free. New edition in the press.

"THE ELECTRICIAN" PRIMERS. In Two Vols. Paper covers, 2s., post free, 2s. 3d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d.

WIRELESS TELEGRAPHY: Signalling across Space without Wires by Electric Waves. By Dr. O J. Lodge. Enlarged Edition. Price 2s. 6d. net.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c. By A. C. Curtis-Hayward, B.A. Price 3s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont. Price 3s. 6d., post free.

FULL CATALOGUE POST FREE ON APPLICATION.

"ELECTRICIAN" SERIES FORTHCOMING BOOKS.

ELECTROMAGNETIC THEORY, VOL. II.—By Oliver Heaviside. The second volume of this important work is in an advanced stage, and will be ready shortly.

PRACTICAL TELEPHONY.—By Dane Sinclair and F. C. Raphael.

PRIMARY BATTERIES.—A work on this subject will shortly be published, bringing the theory and practice of the Primary Battery up to date. The book will be fully illustrated.

SECONDARY BATTERIES.—By E. J. Wade. Fully Illustrated. The Author in this work will deal briefly with the theory and fully with the chemistry, design, construction and manufacture of secondary batteries or accumulators.

"THE ELECTRICIAN" WIREMAN'S POCKET-BOOK.—"The Electrician" Company will shortly publish a valuable pocket-book for the use of those engaged in wiring work, both external and internal.

CARBONS FOR ALL ELECTRICAL PURPOSES.—By Francis Jehl. A work will shortly be published dealing fully with the manufacture of carbons for all electrical purposes. The book will illustrate the machinery and apparatus used in carbon manufacture on the Continent and in America, and will give the latest practice in this important subject.

THE ELECTRIC ARC.—By Mrs. Ayrton. This work will shortly be published, and will contain an historical sketch of the early experiments on the electric arc, as well as the important results of recent research.

SPECIAL NOTICE.

NOW READY.—Vol. XLI. of "The Electrician," bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

A complete set of the Second Series of "The Electrician" can now be supplied. These sets are very scarce, and early application should be made.

CONCENTRIC WIRING.

Since the introduction of pressures of from 200 to 250 volts at consumers' terminals, it has become usual on three-wire systems to connect the middle or neutral wire to earth. This development of central station practice, forbidden at one time by the Board of Trade when lower terminal pressures were in vogue, and now strongly recommended, if not mildly insisted upon, by the same authority, leads one to the consideration of a system of house-wiring which has hitherto been almost ignored by engineers devoting themselves exclusively to the public supply of electrical energy. The form concentric wiring has usually taken is that of an insulated conductor on which all the fuses and switches are connected, entirely enclosed by another conductor serving simultaneously as an armouring for the wire or cable and as an uninsulated return circuit for the current. It is usual to make this return conductor of slightly larger sectional area than the internal one, and to preserve its continuity throughout, from the caps of the lamps themselves, through all branch and main fuse-holders and switches to the switchboard in the dynamo room. When this system is carried out thoroughly the switches and fuse-holders have not only metal covers, but also metal bases, the latter actually forming part of the circuit, and where the fittings do not afford in themselves a continuous conducting sheath of sufficient section from the lamp-holders to the metal ceiling rose, joint-box or socket, "concentric flexible" takes the place of "twin flexible" or "electrolier wire." A system involving the use of an uninsulated return circuit could naturally not be employed in connection with networks of mains each pole of which had to be maintained well insulated from earth, and in consequence this form of concentric wiring was not used until quite a recent date in any house connected to public supply mains. Obviously the outer conductor could be insulated as well at the inner one, but this destroys to a considerable extent the simplicity of the system, renders the jointing more difficult and increases the cost. The

Digitized by Google

only system of concentric wiring with both poles insulated which has been employed to any considerable extent is, we believe, one devised by the engineer of the Harrogate electricity works, in which town it is used on several consumers' premises.

Possibly the chief advantage of concentric wiring with an uninsulated return is that it permits of no half measures so far as faults are concerned; leakages to earth and wire-to-wire faults are one and the same thing. Any damage to the wire, unless it occasion an absolute discontinuity in the outer conductor, can do no more than cause a current to flow through the insulation from one conductor to the other until it has assumed sufficient magnitude to melt the fuse protecting the circuit in question. Another great advantage is that the number of fuses required, and consequently the number of extinctions through stale and loose fuses, is diminished by a half. The system also simplifies and improves the design of lamp sockets and lamp-holders. For instead of it being necessary to have two contacts in the lamp socket for use in bayonet holders, and two spring pins in the holders themselves, one only is required. Lastly, the replacement of the mechanically weak porcelain by metal, in the bases of fittings, appeals strongly to the engineer. The fact remains, however, that the present double wiring is safe enough and good enough, and a decrease, say, of 50 per cent., in the extremely small number of electrically-caused fires, and a similar decrease in the number of local interruptions of electric current would not justify any appreciable increase in the cost of electric light fitting. Patentees and manufacturers of concentric systems of wiring often urge that their systems are as cheap as, or cheaper than, the rival systems in wooden casing or in iron tubes, but at present we do not think that this is the case when a fair comparison is made. It is obviously unfair to take, as is sometimes done, on the one hand, the usual system of two wires encased in wood and buried in the plaster of walls, and, on the other, a concentric system of bare armoured wire placed on the surface; and if the estimate for a drawn-in system is adopted for comparison the concentric system estimated for should be a drawn-in one also. Are, then, the advantages gained by the use of an improved method of wiring worth an additional expense? The answer is no, not in the present condition of the electric lighting industry. But given an opportunity for this class of electric light fitting to be more widely used, so that both the manufacture of the various fittings and their erection may be done in a more economical manner than now, it will, we believe, be able to compete on an equal footing as regards cost with the methods more popular to-day. We may go a step further. With ordinary wiring, as it is at present carried out in buildings, a potential higher than 250 volts above that of the earth, would be associated with danger to person. However carefully the wiring be carried out, there is a possibility of accidental contact with a bare wire or piece of metal. The risk is, we admit, a small one; but we may mention that a case has recently been brought to our notice in which a person inserting a wall-plug received a serious shock and burn (presumably through a bare flexible wire) on an installation connected to a system where there are 400 volts between the outers. With concentric wiring, however, the chance of receiving a shock is very minute indeed, every part of the inner or charged conductor being surrounded by the outer conductor at a comparatively low potential. When higher potentials than 250 volts are allowed within buildings it will probably be after a general introduction of concentric wiring.

One question remains to be settled, however, before concentric wiring can be extensively connected to public supply mains. Where is the earth connection to be? The only town in which concentric wiring has been exclusively adopted is Guildford, where the public supply has been provided by the Safety Concentric Wiring Co. Here there is no direct earthing at all, either at the station or at the feeding points. The mains from the station 'bus bars are bare concentric, run in wooden troughs filled with bitumen, the service wires are jointed "solid" to the distributors, and are also insulated from earth until the house terminals are reached. Within the houses, however, the outer conductors are bare. The supply is on the three-wire system with a pressure of 200 volts on each side. Up to the present we believe no cases of electrolysis have occurred, nor any complaints of disturbance to telegraph circuits, but it must be borne in mind that the system is a very small one, there being only seventy-two consumers, and it has been in operation but two years. It appears to us that to make a good earth at the feeding points would afford more security. At Guildford a consumer might find it possible to utilise the difference in potential between a water or gas pipe and the sheathing of his wiring, say, to ring his electric bells or to light miniature lamps. Electrolysis under natural conditions need not be anticipated, however, if there is an earth somewhere on the system, for it is the neutral wire of the three-wire system that is earthed, and the currents through it are therefore mostly local. At all events, the 7 volts drop in pressure allowed to tramways on their return circuits would hardly be approached.

We will mention one more point, this time adverse to earthed concentric systems, although perhaps not of supreme importance. A cable-fault developing in a side by side or insulated concentric system can, with proper testing arrangements, often be detected in the form of a slight earth before it has any serious effect on the supply. But so soon as the system is earthed throughout, *i.e.*, at more than one point, no insulation tests during supply are of any avail (except perhaps in the case of feeders), and a defect in the network is not noticed until it has become a short-circuit. Thus, what is an advantage in house wiring becomes a drawback so far as the street mains are concerned.

In concluding this somewhat lengthy examination of the arguments for and against concentric wiring, we will express the hope that another central station will follow in the lead of Guildford, and adopt it experimentally.

CONTEMPORARY ELECTRICAL SCIENCE.

[Compiled by E. E. Fournier d'Albe.]

Magnetic Deflection of Open-Air Discharges.—The analogy between open-air and vacuum discharges has already been well established by Toepler's work on their stratification. It remains to show that open-air discharges are subject to magnetic deflection. J. Precht proves that they are. The amount and distribution of the deflection depends upon the shape of the electrodes, but deflection is equally observed in spark, brush, and glow discharges. If the anode is pointed and the cathode blunt, the length of gap 8mm., and the difference of potential 8,600 volts, a field of 7,000 units produces a very decided deflection of the path of the sparks, accompanied by a fall in the potential by about 1,000 volts. The deflection is limited to that portion of the path which lies between the centre and the cathode, and is accompanied by a brightening. When the gap is widened, brush discharge sets in, but the spark discharge is restored by a strong magnetic field. On still further widening, the brush discharge is re-established, but the magnetic field alters its oval shape, and

Digitized by Google

concentrates it into the equatorial plane. At the same time, a plane anode is strongly etched. A peculiar phenomenon is observed when the magnetic field is parallel with the spark gap. On mounting the electrodes over a sensitive plate, the end of the anode column detaches itself from the neighbourhood of the cathode and wanders slowly towards the anode, leaving a track on the plate which is curved according to the direction of the field.

[PRECHT, *Wied. Ann.*, No. 12, 1898.]

A New Influence Machine.—W. R. Pidgeon has improved his influence machine in the direction of cheapness and utility for X-ray work. The machine consists of one or more pairs of glass discs mounted on a spindle and running in opposite directions, with earthing brushes arranged similarly to a Wimshurst machine. But the sectors receive their charge at a moment when they stand between two charged inductors, and their capacity is at a maximum. The machine may be regarded as a condenser, the plates of which can be charged in one position, then shuffled to bring the positives and negatives together, and thus discharged. Each sector is embedded in an insulator, and only the brass contact knob projects. Hence it can receive a charge on each face as it stands between the disc and the inductor, like a plate in a condenser. It, therefore, carries forward a double charge as compared with that carried forward by a machine without inductors. Again, the drop of capacity and consequent rise in potential of the sector as it moves away from the inductor is so great that the induction of the machine is also practically doubled, and hence the total output is multiplied by four. To quote some figures: A Pidgeon machine with one pair of plates requires 18 sq. ft. of area to pass the collecting brushes for spark. A 15in. Wimshurst machine requires 70 sq. ft. The Pidgeon machine will work in any weather, since hardly any metal is exposed.

[PIDGEON, *Phil. Mag.*, December, 1898.]

Genesis of the Point Discharge.—Let a needle-point be mounted opposite a metallic surface earthed through a galvanometer. If the needle-point is then maintained at a potential which exceeds a certain value the galvanometer indicates a constant current traversing the air between the point and the metallic surface. Hence, under the influence of the electric force, the air has been converted into a conductor of definite conductivity, though this conversion may possibly be confined to the immediate neighbourhood of the needle-point. E. Warburg endeavours to solve the question as to what amount of time elapses between the establishment of the proper difference of potential between needle-point and surface and the passing of the discharge. He mounted a fine platinum point, obtained by tearing a glowing platinum wire in a nearly closed metallic sphere, and determined, by an automatic interruptor, the current passed immediately after the establishment of the potential, and the current passed after the potential had been established for some time. The results show that the discharge reaches the full value 0·007sec. after establishing the proper difference of potential, and that, therefore, the air does not require more than that short interval to acquire its full conductivity. The retardation which attends spark discharges between spheres is not observed in this case.

[WARBURG, *Wied. Ann.*, No. 12, 1898.]

A Dispersion Model.—Several types of models have been suggested for illustrating the behaviour of waves of various periods when encountering media capable of absorbing such of them as have a particular wave-length. J. H. Vincent has designed one which not only illustrates it roughly, but shows an agreement with Helmholtz's formula of dispersion, $\mu^2 = \frac{n^2 - a^2}{n^2 - b^2}$, where μ is the refractive index, and n the frequency of the incident vibration. Vincent's model consists of a long spiral spring suspended horizontally by a series of vertical threads. Such a spiral spring has often been used to illustrate the propagation of sound and light. In Vincent's model it is loaded with leaden bullets at intervals of about five turns, and to each bullet is attached a weight twice as heavy as the bullet, by a thread 56cm. long. Without these weights the loaded spring represents the open ether. With the weights added it represents a material medium. One end of the spring is set in vibration by means of a metronome. As the frequency increases from 0 to b, the wave-length and the velocity of propagation decrease. When $n = b$ the lower particles are thrown into violent agitation, but when n is a little greater than b the model altogether refuses to propagate the motion, and no waves are observed until n exceeds a. When the frequency is higher the hanging weights are unaffected, and the velocity becomes independent of the frequency. The same thing happens when short impulses are given, corresponding to the X-rays of modern theory.

[VINCENT, *Phil. Mag.*, December, 1898.]

Conductivity Method of Studying Solutions.—The conductivity method of determining whether or not double salts exist as such in solutions consists in a comparison of their observed conductivity with what it is supposed their conductivity would be if the constituent salts were entirely uncombined. The difficulty which has always presented itself has been to determine what the conductivity would be on this assumption. The difficulty vanishes in the case of extremely dilute solutions, because in their case it follows from the principle of the superposition of small effects alone, that, if no double salt exists, the specific conductivity will be equal to the arithmetical mean of the solutions of the constituents taken separately. J. G. MacGregor and E. H. Archibald show by practical demonstrations that, once the molecular conductivities at infinitive dilution are known, the conductivities of fairly complex salt solutions can be calculated with the aid of the dissociation theory of electrolytic conduction, even in its present imperfectly developed form. Thus the conductivities of all solutions containing two electrolytes with a common ion is calculable up to a concentration of about 1 gramme-equivalent per litre. The conductivities of mixtures of equi-molecular simple solutions of zinc and copper sulphates, or of potassium and sodium sulphates are calculable within the limits of observational error up to a concentration unity.

[MACGREGOR and ARCHIBALD *Phil. Mag.*, December, 1898.]

Genesis of Electric Sparks.—By an extension of the work of Feddersen and of Trowbridge, B. Walter has obtained some photographs of electric sparks which elucidate several hitherto doubtful points. He mounted a rapid plate upon a little car moving on rails and driven by a falling weight. The rotary interruptor of the induction coil was worked at such a rate that at least two sparks were recorded on the moving plate. This, while ensuring a record, also furnished a measure of the time. The records all agreed in showing several discharges succeeding each other at intervals of $2{\cdot}7 \times 10^{-4}$sec. The first discharge was by far the strongest, and the track of the spark showed several branches and brushes. The portion of the spark at the negative pole was always more strongly marked than that at the positive pole, evidently owing to the difference in the actinic powers of the anode and the cathode light. The successive partial discharges, though all in the same direction, show an alternate weakening and strengthening, due to the surgings of the primary current in the condenser. A further analysis of the sparks reveals a process of a more complicated but highly interesting nature. It is seen that every spark is preceded by several brush discharges. Each brush discharge is separate from the preceding one, which is usually of the opposite sign. Thus a small brush will start from the negative pole, and another shortly afterwards from the positive pole. Then a larger brush will start from the negative pole through the path marked out by the first one, and will then bend aside and proceed a step further, and so on until the whole gap is bridged and the first spark passes. When the analysis is not very minute the preliminary brushes appear as appendages to the first spark. Such appendages are also seen in lightning photographs. Lightning flashes are, therefore, probably also preceded by pilot brush discharges.

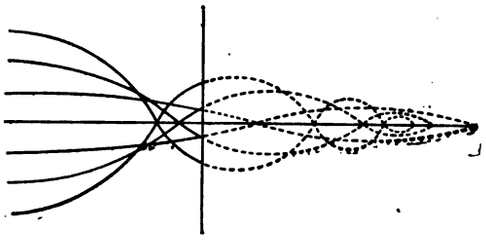
Magnetic Suction of Cathode Rays.—Early this year (see *The Electrician*, Vol. XL., p. 782), Wiedemann and Wehnelt described the appearances presented by cathode rays, propagated, not across a magnetic field, but along it, towards the pole of a magnet. They stated that the rays were twisted into a series of nodes and ventral segments. K. Birkeland amplifies these facts by further studies, showing that the arrangement of the nodes is not quite so simple as described by the former investigators, but is equally within the grasp of the emission theory. He mounted a Maltese cross in the path of the rays, and brought the magnet gradually nearer to the end of the tube impinged upon by the cathode rays. By moving the cross and the magnet into various positions, the course of the rays could be completely mapped out. As the magnet approached, the shadow of the cross, upright at first, turned about the magnetic axis, and both the shadow and the luminous spot diminished in size. The rotation was such that when the rays were directed upon a north magnetic pole, the cross, as seen from the pole, turned in the direction of the hands of a watch. The patch alternately increased and



decreased in size. The general course of the rays is seen in the figure, where the outer rays show more numerous segments than the inner ones.

[Birkeland, *Archives de Genève*, September, 1898.]

THE COMMERCIAL AND BUSINESS ASPECTS OF MUNICIPAL ELECTRICAL SUPPLY.

BY ALFRED H. GIBBINGS, M.I.E.E.

(*Continued from page 82.*)

Hiring-out of Motors, Arc Lamps, and other Apparatus.

The hiring-out of electric motors and other apparatus is an innovation of very recent growth in connection with municipal electricity supply. The scheme was first put into operation in November, 1896, by the Bradford Corporation, who were also the first municipality to own an electricity supply station. The movement is, of course, merely a corresponding enterprise to the letting out on hire of gas stoves, which not only every municipality owning a gas works, but also every gas company, knows to be a sound and valuable commercial arrangement. It is true that there must be but a very few, if any, instances in which gas engines are let on hire, and the reasons are palpable. They are cumbersome, heavy and complicated machines. They occupy considerable space, and cannot conveniently be stored. They consist of many parts which have to be separately conveyed to the place of erection, and the engine then built up. They cannot be sub-divided into a number of small engines for direct-coupling as in the case of electric motors, and their operation requires skilled attendance, and involves comparatively frequent overhauling. The chief reason, however, why gas engines are not more extensively let out on hire is undoubtedly the fact that the necessity for developing business in this direction has not been felt, nor is it likely to be. Even with regard to electric motors, the matter of selling so many more units is not in itself nearly so important as the time of the day during which those units are sold. It is the "day load," however comparatively small, which is such a beneficial factor in the economical production of electricity. In the case of gas, this factor is practically negligible, owing to the immense superiority of storage possibilities. In addition to this, the gas stove is an admirable subsidiary in the business of gas supply, for it is as much more efficient than an electric stove for cooking purposes, as the electric motor is superior to the gas engine for power purposes. Up to such a point, gas and electricity seem to stand pretty much on an equal footing, considered as business enterprises, but in one respect municipalities possess an important privilege in connection with gas undertakings. For the purpose of purchasing gas stoves to let on hire, a local authority has power to borrow money. Up to the present time, the Local Government Board have refused to sanction similar borrowing powers for purchasing electric motors for hire. The reasons have been already given in the first portion of this series of articles, to which, therefore, we refer the reader. As an expedient, however, the necessary capital can be raised by a rate, which could be redeemed when, at some future time, perhaps, borrowing powers may be granted. The advantages of the electric motor have already been fully dealt with in the preceding section, and hence we have now to deal only with the reasons for encouraging the wider and more rapid adoption of electricity generally and electric power in particular. Such reasons will apply equally to motors, arc lamps, and any other piece of apparatus considered useful to the supply. The claims herein set forward have been substantiated by two years of actual experience in connection with the Bradford Corporation Works. The extent to which it has grown will be seen in the tables and references given. Bradford has the advantage of a 3-wire continuous current system of electricity supply, with potentials of 230 volts on each side of the system respectively. Motors can, therefore, be wound for either 230 volts on 460 volts. Arc lamps are arranged to burn 2 or 4 in series or 230 volts, and heating and cooking apparatus is designed for 230 volts.

It is often asked what are the obstacles which stand in the way of the more general adoption of electric motors and electric lighting. These, upon investigation, will be found to be one or more of the following, viz.:—

1. The extreme aversion to innovations which characterises the industrial world, in this country especially.
2. The existence of other motors in good working condition, such as steam, gas, oil and hydraulic engines.
3. The unsuitability of high-periodicity single phase alternating currents of electricity for motive power purposes.
4. The want of capital to lay out in new machinery or apparatus.
5. The want of confidence in the electric motor by the non-technical manufacturer,

The first and last of these are very often overcome by the hire system. The incentive to give a new article or method a trial is generally created when the risk of failure is reduced to a minimum and the pecuniary condition is small. This has been exactly the experience in Bradford, where it was found that after both motors and arc lamps had been let on hire for six months in many cases offers were made to the Corporation by the users to purchase the apparatus outright. It will also be seen by reference to Tables XVI. and XVII. how rapid has been the increase in the demand for motors and arc lamps. The most probable explanation in this case is that the singularly appropriate form of supply has created the demand. The advantages of these particularly efficient classes of apparatus has soon been appreciated, with the result that ordinary business competition has rendered their adoption absolutely necessary.

With regard to the second of the obstacles given above, it is only a question of time, for, of course, existing motors, sooner or later, will have to be replaced. An instance which recently occurred in Bradford may be of interest. A small manufacturer had a breakdown with his gas engine. He applied immediately for an electric motor on hire from the Corporation. He was informed that he could not be supplied, as his workshop was a considerable distance from the Corporation supply mains. At first he threatened to have his gas engine repaired, but found this did not have the desired effect. Shortly afterwards another application was made by the same individual for an electric motor for premises adjacent to the existing mains. He had decided to remove from his original premises and to extend his works for the sake of driving by electricity.

Digitized by Google

Where the power to purchase exists the buyer will probably have little or no experience or knowledge of electrical matters to guide him in his purchase. If his means are at all limited he will be tempted to venture on a cheap line, and become the dupe of those who simply make to sell. The solution of these difficulties, which to my mind appears the most satisfactory, because it is the one fraught with the most advantages to all concerned, is that the owners of electricity supply undertakings—whether a public company, municipality, or other local authority—should themselves purchase good reliable motors, &c., and let them out on hire. Antecedently this scheme may appear a sort of parental regime, but it is suited to present circumstances at any rate, and experience proves it to work well.

The following Tables, No. XVI. and XVII., will show the development which has occurred in the adoption of motors and arc lamps respectively since the hire system has been introduced at Bradford :—

Table XVI.—(*Motors*).

Year.	Number of motors supplied from Corporation mains.		Total.	Board of Trade units sold per annum.
	Owned by consumer. (Not on hire.)	Owned by Corporation. (On hire.)		
1895	35	nil	35	35,919
1896	23	7	30	54,972
1897	14	39	53	117,176
*1898	6	46	52	63,820

* Six months only.

From this table it will be seen that the increase in electricity supplied for motive power in 1896, in which year the hire system had been in operation for *two months only*, was 19,053 units; in 1897 the increased sale over 1896 was 52,204 units; and in the present year the increase is likely to be 82,824 units, or a sale of 200,000 units or 41 per cent. over 1897.

Table XVII.—*Arc Lamps*.

Year.	Number of arc lamps supplied from Corporation mains.	
	Owned by consumer. (Not on hire.)	Owned by Corporation. (On hire.)
1889	50	Nil.
1890	44	,,
1891	57	,,
1892	68	,,
1893	61	,,
1894	52	,,
1895	52	,,
1896	74	14
1897	21	66
*1898	12	100
Total.....	491	180

* To Sept. 30, 1898.

The following are the conditions upon which electric motors are let on hire by the Bradford Corporation :—

1. The rent is due in advance on January 1st and July 1st in each year, the first payment to be made at the time of signing the agreement, and before the motor is connected to the Corporation mains. In the event of the accounts for hire or for current becoming overdue the supply will be cut off.

2. The rent will include the conveyance of the motor from the Corporation stores to the premises of the hirer, if such premises are upon the ground floor. If, however, the motor is required in a basement or upon a higher level than the ground floor, the hirer must pay the cost of raising or lowering the motor to such position, as follows :—

½ H.P. and 1 H.P. motors	10s.
2 ,, 3 ,, ...	20s.
4½ ,, 6 ,, ...	30s.
10 H.P. motors	50s.

3. The hirer must also provide suitable foundations (timber being usually sufficient) upon which the motor will be secured by the Corporation. Sizes of foundations for the different sizes of machines may be obtained at the offices.

4. The rent includes supplying and fixing the necessary starting switch, but all other accessories, such as oil, carbon tips, special pulleys, &c., must be paid for by the hirer and obtained from the Corporation stores, Bolton-road. The fortnightly inspection by an authorised inspector (who will be in uniform) will be free of charge.

5. The necessary wiring from the Corporation terminal box to the motor, including cut-outs, main switches, &c., must be provided by the hirer, and will be subject to the same conditions and tests as apply to wiring for the electric light. The meter must in all cases be fixed adjacent to the service terminal boxes.

6. The supply of the motor and the current will also be subject to the Board of Trade Regulations relating to electricity supply, to the Rules and Regulations of the Electricity Department of the Corporation and the Electric Lighting Acts, 1882-1889.

Rent and Particulars.—Motors.

Horse-power.	Speed.	Diameter of pulleys.	Volts.	Amperes.	Rent per annum.
½ B.H.P.	1,700	4in.	230	3	£1 10 0
1 B.H.P.	1,450	4in.	230	5	2 0 0
2 B.H.P.	1,200	5in.	230	9	2 10 0
3 B.H.P.	1,100	5in.	230	12	3 0 0
4½ B.H.P.	1,000	6in.	230	18	4 0 0
6 B.H.P.	800	7in.	230	22	5 0 0
10 B.H.P.	800	10in.	230	36	8 0 0

The following are the conditions under which arc lamps are let out on hire by the Bradford Corporation :—

1. The rent is due in advance on January 1st and July 1st in each year, the first payment to be made at the time of signing the agreement, and before the arc lamps are connected to the Corporation mains. In the event of the accounts for hire or for current becoming overdue, the supply will be cut off.

2. The rent will include fixing the lamps in the premises of the hirer. The hirer must provide and fix in position the necessary hooks or brackets on which the lamps are to be placed, and a sufficient length of electric cable must be left at the brackets to enable the lamps to be connected up.

3. The lamps will be supplied complete with globes and resistances, and will be left in satisfactory working order. In the event of any globe being broken, or any terminal or portion of the lamp becoming burnt, the hirer must pay the cost of replacing the defective part. These defects and breakages must be remedied with the least possible delay.

4. The rent includes periodical inspection by an inspector in uniform, whose duty it is to report upon the condition of the lamps and installation.

5. A separate meter must be placed in the arc light circuit, in the event of there being also incandescent lamps in the same installation.

6. The necessary wiring from the Corporation terminal box to the arc lamps, including cut-outs, main switches, &c., must be provided by the hirer, and will be subject to the same conditions and tests as apply to the other installation wiring.

The supply of the arc lamps and the current will also be subject to the Board of Trade Regulations relating to electricity supply; to the rules and regulations of the Electricity Department of the Corporation; and the Electric Lighting Acts of 1882-9.

Rent and Particulars.—Arc Lamps.

Type.	No. in series.	Amp.	Approx. c.p. of each lamp	Rent per annum.	Total cost per hour for current.
Enc. arc (single carbon)	2	5-6	500	£1 1 0 each	5d.
Open arc (double carbon)	2	5-6	500	1 1 0 ,,	5d.
,, ,,	2	10-12	1,000	1 1 0 ,,	10d.
Open arc (single carbon)	4	5-6	500	0 10 6 ,,	5d.
,, ,,	4	10-12	1,000	0 10 0 ,,	10d.

The enclosed type arc lamp requires re-carboning once every 100 hours.

Prices and Sizes of Carbons.

12 millimetres and	12 millimetres (for enclosed arcs)	3d. per pair.
18 do.	11 do.	1⅜d. ,,
12 do.	7 do.	1d. ,,

(These carbons are of the best quality only; inferior carbons are likely to give dissatisfaction and trouble.)

Basis of Charge.—The basis upon which the annual charge for hire should be made is arrived at by adding all the charges consequent upon the capital outlay. These are (1) Interest; (2) Sinking Fund; (3) Depreciation and Repairs. The interest may be taken as an average of 3 per cent. per annum. The Sinking Fund will be variable according to the period over which the capital is borrowed. Usually this is 25 years, and the amortisation is practically equivalent to another 3 per cent. per annum. The rate for depreciation and repairs will depend upon the nature of the apparatus on loan. For motors and arc lamps, the "life" may be reckoned as ten years, and the repairs at the rate of 4 per cent. per annum. This gives a total rate for depreciation, &c., of 14 per cent. per annum. Hence the total charge should be :—

Interest	3	per cent. per annum.
Sinking Fund.....	3	,, ,,
Depreciation, &c.	14	,, ,,
Total	20	,, ,,

Digitized by Google

Therefore, 20 per cent. of the capital outlay should be the annual rental charge. In Bradford, as will be seen in the "Rent and Particulars" already given, only 10 per cent. is charged. The 10 per cent. for actual depreciation has been taken out of the annual rental and allowed for in the price charged per unit. By this arrangement it was considered that greater inducement would be offered to adopt the apparatus on hire. This department may also with advantage undertake the sale of such articles as are required for the use and operation of the apparatus on hire. For motors, oil, carbon brushes, &c., should be sold, and for arc lamps carbons and globes.

The following rules, printed on stout card or strawboard, should be supplied with each motor and hung up in a convenient place adjacent to it:—

Directions to be Observed to Ensure the Safe and Satisfactory Working of Electric Motors.

1. The motor must never be started with the load on.
2. The motor must always be started and stopped by the starting switch. The main switches may be left *open* when the premises are not occupied, but they must always be *closed* before starting the motor.
3. If the starting switch is in order the speed of the motor will be slow on first closing the circuit, but full speed will be attained after 15 to 30 seconds. It must not be used until full speed has been attained.
4. If the motor appears to start up too rapidly notice should at once be sent to the electricity office, Town Hall, as the motor may be damaged if the defect is not remedied.
5. If the motor starts up too rapidly, or with the load on, the main fuse will probably be blown.
6. Before starting see that the oiling arrangements are satisfactory; oil should not be allowed to run on the bearings when the premises are closed.
7. Suitable oil may be obtained at the stores, Bolton-road Electricity Works. Price 2s. per gallon.
8. The brushes (*i.e.*, the carbon contacts on the commutator) must not be lifted under any circumstances. If the carbon has worn down too low, which may be ascertained by the loud, scratching noise which the holders make on the commutator, new carbons should be at once put in and the attention of the inspector called to the matter, or notice sent to the Town Hall. Neglect of the above will cause scoring of the commutator and will damage the machine.
9. The inspector will examine the motor once a fortnight. You are requested to allow him to start and stop the motor and to make what examination he thinks necessary.
10. The inspector will be in uniform, and will also carry a ticket of authority to inspect.
11. The motor should not be left running when not in use; observance of this will tend towards considerable economy.
12. Irresponsible persons, or those unacquainted with electric motors, should not be permitted to do anything whatever in the nature of a repair or adjustment under any circumstances. Attention will always be given to irregularities on notification at the office at the Town Hall or in writing.

(To be concluded).

IMPROVEMENTS IN MAGNETIC SPACE TELEGRAPHY.*

BY DR. OLIVER LODGE, F.R.S.

PART I.—*First Portion.*

The general principles of electric space telegraphy—or wireless telegraphy, as it seems to wish to be called—are fairly old; and without going into the history of the subject, with which I need not trouble you, since it has been admirably summarised by Prof. Silvanus Thompson in his lecture to the Society of Arts, I may recapitulate the three chief methods that have been tried. First and oldest the earth current or leakage method, wherein a powerful current conveyed to the earth or sea by two well-separated electrodes causes a slight difference of potential between two other well-separated tapping electrodes at a distance, and thereby produced a feeble current through a joining wire, which can be detected telephonically or galvanometrically, or in any other convenient and known way. I am under the impression that this utilisation of earth conduction for the purpose of conveying messages has played a greater part in the past, and is perhaps destined to play a greater part in the future, than most people suspect. When, for instance, as in Mr. Langdon Davies's experience, phonoporic currents have been heard in very distant telephone trunk lines, it is difficult to be sure how much of the effect is due to a true induction from wire to wire, and how much of it is due to conduction—not only conduction through the soil from earth-plate to earth-plate, but conduction also through metals, whether gas pipes or overhead wires or other conductors arranged for other purposes. Whenever an open circuit is employed, with earthed terminals, conduction is liable to assist induction; and this may very likely be regarded as an advantage. It may also be to some extent a disadvantage, owing to its resulting in the mixing of messages; it may, in fact, contribute to ordinary telephonic cross-talk.

The second method that has been tried for purposive space telegraphy is the method by magnetic induction between two insulated line wires stretched parallel to one another along opposite coasts. This method, as is well known, has been tried under the auspices of the British Post Office, and is known as Mr. Preece's method. It is, I think I am right in saying, the only system in actual regular work; for near Cardiff, between Lavernock Fort and the neighbouring fort on the island of Flat Holm, I have myself seen it at work, and have admired the ingenious system of "call" devised by Mr. Evershed and there employed. I desire to say that when I gave a short preliminary note to the British Association at Bristol this year, on a "call" that I had invented, I was unaware of Mr. Evershed's work in the same direction. He has undoubtedly achieved the result there aimed at, though with the expenditure of a good deal of power; and had I known, I should certainly have referred to it in my communication at Bristol. But after the Bristol meeting Mr. Preece gave me permission to visit Lavernock, and I went in company with Mr. Partridge, the telegraphic superintendent at Cardiff, to whom also I am obliged.

In the third system of space telegraphy—that by Hertz waves—the public owes its knowledge and interest also to Mr. Preece; for, had Mr. Preece not taken up the subject, very few persons would, in all probability, have heard of Hertz waves and Branly detectors and coherers to this day. As it is, owing to Mr. Preece's great influence and power of lecturing, this third and most recent method has become the best known of all; and, indeed, Italy is generally credited with the whole discovery. I do not intend to refer to this interesting method again to night, but before leaving it, it may conduce to clearness if I explain wherein the Hertz-wave method, at which I have also worked in conjunction with Dr. Alexander Muirhead, differs from the older magnetic inductive method of Mr. Preece, Willoughby Smith, and others.

Every alternation in a suitable medium produces waves in one sense, but the intensity of those waves is immensely dependent on the rapidity of the alternation. A rapid pulsation of air, in and out of a hollow vessel like a resonator, may cause an extremely loud sound; a slow pulsation, of the same or even of much greater amplitude, would cause no perceptible effect, beyond an alternate rise and fall of a sensitive barometer. Again, a reed vibrating slightly but quickly is audible at a distance, while a fan vibrating strongly but slowly is not audible at all. The waves emitted by the one are strong, by the other are exceedingly weak. A magnetic alternation of sufficient rapidity induces an alternating electrostatic field, and is, therefore, accompanied with emission of energy. A slow magnetic alternation is practically unaccompanied by any electrostatic effects, and so, practically, all the energy emitted at each pulsation returns again to the source. For a progressive wave must necessarily have half its energy static, and half of it kinetic energy; whereas in ordinary current induction all the energy is kinetic.

Interrupting the explanation for a moment to touch on a practical point: It might seem, from what we have so far said, as if all the advantages lay with the rapid vibration or wave method. But when really large distances are contemplated, or when obstacles intervene, its advantages diminish and ultimately disappear; for slow magnetic pulsations are independent of all obstacles, except actual iron, if they are slow enough, and are only slightly weakened by conductors, whereas rapid pulsations or true waves are stopped by conductors, and are greatly affected by obstacles. It is probable, as I have hinted above, that earth-conduction plays a considerable part in some of the coherer signalling which is supposed to occur by means of waves in space; and in all cases it is a possibility to be constantly borne in mind. The coherer is a detector of electric jerks transmitted by the earth or by uninsulated conductors such as gas pipes, and the response of a coherer is no conclusive demonstration of the receipt of actual Hertz waves.

To detect the radiation of energy, something capable of responding to waves, such as an ear, an eye, or a coherer is appropriate; to detect the fluctuations of pressure or of magnetic field, something akin to a barometer or magnetometer would seem to be appropriate; but, inasmuch as these instruments only indicate the state of things at their immediate locality, another device can be employed which shall integrate the effect over a considerable area and therefore be much more sensitive. Such a device is afforded in the case of magnetism by Faraday's current-induction. A circuit connected with any electric detector, such as a telephone, may surround a large area and give an induced current depending on the variation in the total lines of force passing through the entire area.

In the Lavernock signals, considering them as due to wire induction, the inducing and induced areas are both long narrow strips in a vertical plane, with their long sides horizontal and their faces parallel; each being constituted by the space between a long over

* Paper read at the Institution of Electrical Engineers, Dec. 8, 1898.

Digitized by Google

head line on posts and the return earth—or, rather, sea—circuit. But in some interesting experiments made by Mr. Stevenson near Edinburgh he employed a horizontal coil of wire approximately circular—in one case utilising some farm fencing, I believe—and by means of a battery and key at one station was able to hear Morse signals in a telephone in another like coil half a mile away. This certainly resulted from pure induction, and it may be considered to represent the closest approach hitherto made to the method I have to bring forward to-night.

Unfortunately, Mr. Stevenson made a slight error in the theory, and perhaps for that reason did not continue the attempt over larger distances. He says that with a given number of ampere-turns the hearing distance increases with the square root of the diameter of one of the coils, or with the simple diameter of both coils, thus making it necessary to double the size, quadruple the area, of each coil if the distance is to be doubled; and, since he used 1,600 yards of wire in each coil to signal half a mile, he may have considered the cost prohibitive for any really great distances, as, indeed, it is, with mere unaided coil induction. But, in truth, the law of distance is not the square root of the diameter, but the two-thirds power, *with a given primary current;* and so doubling the circumference of each coil will enable signalling over more than double the distance, if other things can be kept the same. It is true, however, that for such magnification the thickness of the wire must be magnified likewise, or else more power will be consumed in the enlarged coil; and this consideration, together with others shortly to be stated, does speedily make the cost prohibitive, unless some fresh revolutionary devices are employed.

The devices I have to lay before you to-night contain nothing new in principle—*i.e.*, they involve no discovery—but, inasmuch as they make practical over big distances what has been actually successful over small distances, I venture to attach some importance to them, and think them worthy of your attention. First I have to explain my system of magnetic induction telegraphy, and next the extra sensitive receiving instrument which may be employed with it.

The chief feature of my magnetic system is the outcome of an electric resonance experiment which I described eight years ago (see *Nature*, Vol. XLI., p. 368), viz., the experiment of the syntonic Leyden jars. The term "resonance" is generally and properly understood as having an acoustic significance, and where no reference to sound is intended I advocate the use of the more general term "syntony" to denote the sympathetic response between two vibrators attuned to the same "note," or more generally to the same frequency of vibration, whether that vibrator be mechanical or electric or magnetic. Two similar Leyden jars connected to similar circuits are, or may be, thus syntonised, and any electric oscillation in one causes a feebler electric oscillation in the other; the medium of communication in this case being the alternating magnetic field between the two circuits, the lines of force of the one circuit penetrate the other, and by their fluctuation cause an alternating electromotive force of feeble intensity. In a distant circuit *not* containing a Leyden jar, and therefore not susceptible of any tuning, because it has no natural frequency of vibration, nothing can be perceived; but when a Leyden jar exists in a circuit, that circuit has at once a natural frequency of vibration which may be syntonised with that of the emitting circuit, and in that case the intensity of the reverberating induced electromotive force may rise as high as several thousand volts, and cause a spark over a very perceptible air-gap.

Now, for telegraphic purposes, I replace the Leyden jar by a condenser of considerable capacity, and the circuit of the jar becomes a large horizontal coil of wire—it may be of one turn or it may be of more; and the frequency of vibration, instead of being the million or so per second appropriate to Leyden jars, becomes the thousand or even hundred per second appropriate to sound. Hence, instead of using a spark gap to detect the disturbance, I use either a coherer or else a telephone as a shunt to the receiving condenser. Further, although the momentary oscillation of a spark constitutes a possible sender, I generally employ some form of alternating or intermitting machine of considerable power as the sending appliance, and carve its fluctuating current into long and short spells, as everyone else working at the subject has done.*

I have at my house a cable a quarter of a mile long altogether, enclosing an elongated rectangle, say, 150 × 30 square yards, and with that I can hear all that goes on in the neighbouring telephone wires, and can even answer back with a suitable microphonic transmitter; but there being, I suppose, no phonopore in the neighbourhood, I hear no stray musical note; the only musical note I hear is the one belonging to the desired signals when they are being sent to me from an equal length of cable round an equal but squarer contour at the College about two miles away, or 2·5 kilometres in a direct line.

I may say that, although the Leyden jar or condenser constitutes a leading feature of my system, I have occasionally, as an experiment, dispensed with it, and tried what could be done with the area-enclosing circuits alone. But under those conditions, with the power I had at my disposal, I was not usually able to hear anything. I was using a small low-frequency dynamo of the Pyke and Harris pattern, and at the sending end had a current of 10 or 12 amperes going round the circuit, sometimes as much as 25 amperes. Under these circumstances, on the ordinary National Telephone Co.'s telephones, the sound could be heard many miles away—away over in Cheshire, towards the Dee, the signals could be clearly heard, while close to the college the subscribers, unfortunately, became rampant; but through empty space the signals only became audible at a distance of two miles, when a condenser was used and the circuit properly attuned. I am speaking now of the early trials, when no suitable receiving telephone was employed, but only the first to hand. The cable, bought for the purpose of the trial, was described as anti-inductive telephone cable (not exactly the variety required), and it was very badly insulated, having been bought as little more than old materials; but still it might, perhaps, have been expected to do better. Directly the circuits were syntonised, however, there was no difficulty in hearing the note and the signals. I should say that I did not work with the fundamental frequency of the dynamo—128 per second, or thereabouts—but with the third harmonic, which is fairly strong in these Pyke and Harris alternators, of frequency 384. Such a note is pleasanter to listen to than a deep bass, the ear is far more sensitive to it; and, moreover, to attune the circuit to the lower frequency would have entailed a prodigious capacity. As it was I used 28 microfarads, and had to insert the thick wire of a hedgehog transformer in the circuit too, in order to get the induced circuit frequency as low as 384 with the quarter-mile length of cable once round.

I generally used a couple of Ader telephones in series, each of about 70 ohms resistance, and connected them thus as a shunt to the receiving condenser. The resistance of the receiving cable itself was only 0·07 ohm (it consisted of 100 No. 18 wires all in parallel), so that if the telephone had been in series with it a very low resistance winding would have to be employed, and in the early trials I did not happen to have such a telephone handy. I did, however, use a Western Electric loud-speaking telephone of 2 ohms resistance occasionally. A transformer, of course, was sometimes used, but it wastes power. Besides, the low resistance of a transformer winding is apt to be rather illusory when its higher resistance secondary is closed.

At the sending end also condensers were employed, in series with dynamo and coil, in order to strengthen by resonance the third harmonic at the expense of the fundamental. The cable there was about 400 yards of well-insulated telephone cable, consisting virtually of 20 strands of separately insulated No. 16 wire, slung on poles round a squarish contour; but, unfortunately, it was again sheathed in lead so as to be nominally "anti-inductive." I found it best usually to join these 20 wires in five series of four strands each; and the current in each strand being then, say, 6 amperes, I call the whole current in the cable 24 amperes.

The receiving cable I could also at first employ in separate strands, for its 100 wires were supposed to be insulated with thin india-rubber. The first time I heard the note I had 19 of these strands in series without a condenser, constituting a coil of 19 turns, connected to an Ader telephone. Since then, however, the insulation has so much broken down that I am constrained to use all the wires in parallel, which for many purposes is not so convenient.

Advantage of Syntony.

Now proceed to consider more particularly the elementary theory of magnetic induction telegraphy between two large distant horizontal coils, first without, then with condensers; taking the case, however, of an alternating current, and not the simple make-and-break battery arrangement employed by Mr. Stevenson, which obeys somewhat different laws.

The first proposition I wish to maintain is that no unaided simple induction process can work satisfactorily over really big distances unless an altogether prohibitive amount of wire or an extravagant amount of power is employed. This proposition I prove by considering the strength of current induced in the distant circuit. Let a and b be the radii of the two coils, considered circular, n and m their turns of wire, and r their distance apart from centre to centre, this last being considerable: then the mutual induction coefficient—*i.e.*, the total lines of force passing through one coil due to unit current in the other—is

$$M = \frac{n\pi a^2 m\pi b^2}{r^3}.$$

The resistance is

$$\frac{2n\pi a}{\pi c^2}\rho \text{ for one, and } \frac{2mb}{a^2}\rho \text{ for the other.}$$

* Note.—In the original Paper a detailed quotation of Mr. Stevenson's experiment was here quoted, under the belief that signalling to a lighthouse at the Shetlands had been tried; but this was a mistake. The experiment was only a preliminary one near Edinburgh, and does not appear to have satisfied the P.O. officials who helped to conduct it.—O. J. L.

Digitized by Google

The self-induction is

$$4\pi\mu n^2 a\left(\log\frac{8a}{c}-2\right);$$

or, for present approximation—accurate if one coil is like the other magnified—i.e., if they are really "similar coils"—the self-inductions are

$$kn^2a \text{ and } km^2b.$$

Now, if E is the electromotive amplitude maintained in the primary, the current-amplitude induced in the secondary is

$$x=\frac{p\mathrm{ME}}{\mathrm{J_1J_2}},$$

when J_1 and J_2 are the impedances.

For rapid alternations and good stout wire the value of J is not much bigger than p L; hence the most favourable case for the mere pair of circuits without condensers gives

$$\frac{x}{\mathrm{E}}=\frac{\mathrm{M}}{p\mathrm{L_1L_2}}=\frac{nm\pi^2a^2b^3}{pn^2m^2k^2ab\rho^3},$$

which is, therefore, the "virtual conductance" of the whole system.

The first and most important thing we observe here is that p occurs in the denominator, so that high frequency is actually disadvantageous—other things being equal, which they usually are not, because high tones are best to listen to. The next thing to notice is that number of turns of wire occurs in the denominator, so that a single contour is much better than a coil of many turns; except in so far as many turns help to emphasise self-induction at the expense of resistance, and so to bring about the above "most favourable" conditions where resistance can be neglected. Lastly, we observe that the linear dimensions of each coil occurs only once in the numerator, and that their product is, therefore, incompetent to cancel the cube of the distance in the denominator, when both wire and distance are magnified in the same proportion, and when both are big. Observe, we are not here taking the case of a *given current* in the primary, but the more practical case of a given E M.F.

Moreover, we see that extra thickness of wire gives no advantage: if the wire is thin, the induced current will be less than the above; but no increase of thickness can make it greater than the value of x now calculated, viz.:

$$x=\frac{\pi^2ab\mathrm{E}}{k^2pmn\rho^3}.$$

Hence I say that no simple induction system can work over really big distances, unless an altogether prohibitive amount of wire or an extravagant amount of power is employed. If for a certain distance a total length of wire is just sufficient, it is best disposed in equal contours of one turn each; and the ratio between the induced secondary current and the applied primary E.M.F., without allowing anything for the impedance of the receiving telephone, is then

$$\frac{l^2}{16k^2p\rho^3}. \quad \ldots\ldots\ldots \quad (1)$$

To signal double the distance $2\sqrt{2}$ times the length of wire is necessary; and to signal 10 times the distance the necessary length of wire is 32-fold, its thickness being increased at the same time so as to keep resistance down.

Introduction of Condensers.—But now, directly condensers are introduced both into sending and receiving circuits, and are adjusted until each circuit is attuned to the applied frequency, the conditions are greatly altered. When the correct note is reached all self-induction is abolished, and the impedance becomes simple resistance. Hence in this case the induced current is

$$y=\frac{p\mathrm{ME}}{\mathrm{R_1R_2}},$$

or

$$\frac{y}{\mathrm{E}}=\frac{pab\pi^2c^2d^2}{4\rho^2r^3}.$$

The most important thing to notice here is that p occurs in the numerator, so that high frequency is specially advantageous. The number of turns is immaterial, instead of being objectionable, as in the former case, and this fact is often convenient for tuning. And a great gain results from increasing the thickness of the wire, whenever a big distance is to be attempted.

If the whole bulk of wire employed is V, and if it be distributed equally between the two stations, in a single turn at each, the ratio between the secondary induced current and the applied primary E.M.F., again without allowing for the resistance of the receiving telephone (its "reactance" has been already neutralised if it is connected in series), is in this case

$$\frac{p\mathrm{V}^2}{64\rho^2r^3}. \quad \ldots\ldots\ldots \quad (2)$$

Comparing this with (1), the chief difference consists in the position of p; but this is a tremendous difference—representing something like a million-fold factor.

To take a numerical example in illustration of the two cases. Let the applied E.M.F. be 100 volts, the frequency 400 per second, the total length of wire, say, 2 kilometres, and its thickness 2 centimetres (about 5 tons of copper altogether): then

$k=125$ about, $p=2{,}500$, and $\rho=1{,}600$ sq. c.m. per second.

So at a distance of 100 kilometres the maximum received current possible is, by simple conduction without condensers,

$$\frac{4\times10^{10}\times10^{10}}{16\times(125)^2\times2{,}500\times10^{21}} \text{ C.G.S. units,}$$

or 0·0064 *micro*ampere; which is quite insufficient to affect a telephone. Whereas with proper condensers the current might be

$$\frac{2{,}500\times(6\times10^5)^2\times10^{10}}{64\times(1{,}600)^2\times10^{21}} \text{ C.G.S.}$$

or 0·5 *milli*ampere, which is quite a strong telephonic current.

(To be continued.)

TELEGRAPHY BY MEANS OF ULTRA-VIOLET LIGHT.*

BY PROF. K. ZICKLER.

In my previous detailed discussion of this subject,† I concluded by promising to make further experiments over greater distances so soon as I had a metallic projector at my disposal. By the kindness of Messrs. Schuckert and Co. and their manager, Dr. F. Nerz, and with the assistance of their Mr. A. Siegert, I have been enabled to carry out my intention. A parabolic reflector, made of a German-silver alloy, was used as transmitter. Its diameter was 800mm., and its focal length 200mm. It was fitted with a regulating arc lamp requiring normally 60 amperes at 47 volts, and it was placed with its carbons horizontal and in the axis of the mirror, so that only the rays reflected from the mirror were used, and not those coming directly from the carbons. As in my former experiments, I used a receiver in which the electrodes were 5mm. apart, and the rarefaction of the air could be varied and measured. For convenience in the experiments, the glass shutter for screening off the ultra-violet rays was placed at the receiving end instead of at the transmitting end, the object of the experiment being merely to determine if the rays emanating from the projector were sufficient to start the sparks in the receiver.

The experiments were carried out on October 5th and 6th. In tests made on the first day across a distance of 60 metres the rays caused sparks to pass in the receiver without any rarefaction of the air, and without the employment of any means to concentrate the active rays upon the cathode. This pointed to the possibility of overcoming far greater distances now that the transmitter was of greater power. The distance was, therefore, increased to 450 metres. The same quartz lens was used as in former experiments, its diameter being 4cm. and its focal length 15cm. With an air-pressure corresponding to 340mm. of mercury sparks occurred on the removal of the glass plate. This experiment was made with the sun shining. The second day's experiments were made across a distance of 1·3km., when, with the same lens, but a pressure of 200mm., satisfactory results were obtained.

Thus the use of a reflector has increased the distance over which signals could be transmitted 6·5 times. It may or may not be that the use of a larger arc has also assisted, for in my former experiments better results were obtained with a long arc and smaller current than with a short arc and larger current.

I intend to make further experiments with projectors made of a material more suitable for the reflection of ultra-violet rays; the one used in these experiments was of a copper-nickel alloy, and not expressly prepared for the purpose. I will also experiment with larger quartz lenses, and with gases other than air in the receiver.

Wireless Telegraphy.—The *Standard's* Vienna correspondent announces that experiments were made a few days ago at Pola, and are shortly to be repeated, with an improvement of Marconi's system of wireless telegraphy. It is, he says, already possible to determine the presence and course of a vessel distant from six to eight English miles. The improvement is the invention of a young student at the Buda Pesth Polytechnic, named Bela Schefer. The next trials will be made in the presence of Admiral Baron Spaun and several naval engineers. No further details are yet to hand.

ELECTRIC POWER TRANSMISSION AT A SWEETMEAT FACTORY.

Messrs. Geipel and Lange have forwarded us the following particulars of an important installation of alternate-current electric motors for driving the machinery at Messrs. Fuller's new sweetmeat factory at Hammersmith :—

There are in all 14 motors, each of which, with one or two exceptions, drives its own machine. The motors vary in horse-power from 7 H.P. down to ¼ H.P. They are operated by current supplied by the Hammersmith Vestry at a pressure of 110 volts, alternating, with a frequency of 50, and are of the Brown-Boveri single-phase type. The smaller motors are started by means of a resistance, while for the larger sizes the usual condenser is employed. The ease with which the motors can be started by the various attendants is a special feature of the whole installation. It may be noted, for example, that for working the lift there is in use a 2 H.P. motor, which starts up readily with the whole of the belting and gearing thrown on, and yet the starting current does not exceed the full-load current. It has also been found that at times the load on this motor has been double of that for which it was designed, though there has been no breaking out of step, or any damage whatever to the motor. This adaptability of the alternate-current motor to overloading is a feature which is frequently lost sight of, and in this respect it affords a favourable comparison with the continuous-current motor, in which overloading means sparking and wear and tear of the brushes and commutator. It has been noticed in several cases that the motors have been bespattered with sticky sugar and chocolate ; this does not appear to affect their working in the slightest. On the other hand, had they been fitted with exposed commutators, as in the continuous-current system, serious trouble might have been the consequence. The curves in Fig. 1 give details as to the efficiency, drop in speed, power factor, &c., of one of the motors.

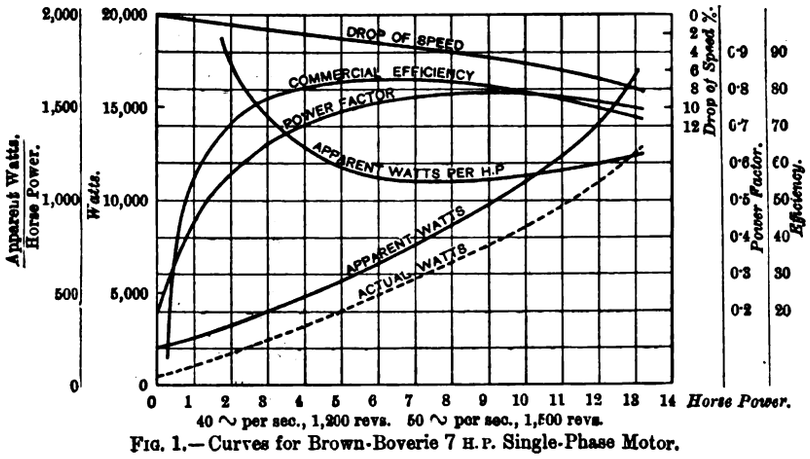

FIG. 1.—Curves for Brown-Boverie 7 H.P. Single-Phase Motor.

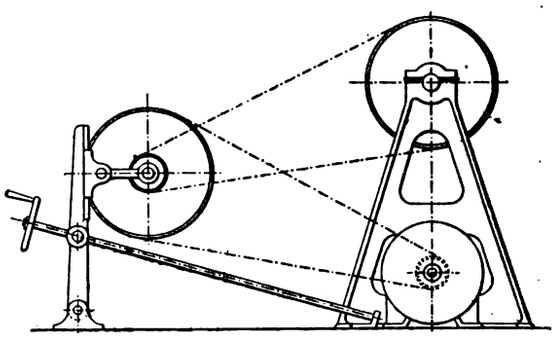

FIG. 2.—Geipel and Lange's Patent Gear for Electric Motors

The speed of the factory machinery being slow, it was found necessary to adopt some form of speed-reducing gear. The three following alternatives were considered :—Spur gearing, worm gearing, and belting. The first two were objected to, chiefly owing to the difficulty of designing special gearing for each machine, the speed of these differing. It was, therefore, decided to adopt belting. This involved the use of a countershaft, and as it was specially desired to obviate the unsightliness and trouble due to countershafts fixed on ceilings, resource was had to a special gear patented by Messrs. Geipel and Lange, which has for its object the transmission of power from the motor to the machine by exceedingly short belts. It will be seen from the sketch of the gear (Fig. 2) that it consists of a swivelling countershaft which can be adjusted to give the exact amount of tension required for the two belts by means of a hand-wheel. It will be seen that by turning the hand-wheel in one direction, the standard is inclined forward, thus loosening the belts and permitting the motor to start light. When the motor is started, the hand-wheel is turned in the reverse direction, thus moving the standard backwards and tightening the belts. This operation is necessary only when starting up on full load. The gearing is compact, and takes up but little floor space, and it obviates the necessity of sliding foundations. It may be interesting to note that no trouble whatever has been experienced by the employees either in operating this gear or in starting and stopping the motors.

It was decided to adopt a separate motor for each machine for several reasons :—

1st. Because it was important that the very best light should be thrown on to the work, and this is not possible with overhead gearing and belting.

2nd. Because the machines are scattered, and are in many cases a long distance apart, which, under another arrangement, would have necessitated running long lines of shafting, with the consequent serious and continual loss of power therein.

The suitability of the separate motor system in this particular case is proved, for it is found that most of the motors are standing for a very large fraction of the whole time, and consequently no power is being lost, as would be the case if a large motor were employed for driving the whole of the machines by long lines of shafting.

The factory is lighted throughout by electricity, there being about 260 lights. The whole of the wiring is on the Andrews' Safety Concentric system, the lamps being arranged in small groups, while each motor has its own circuit direct from the main switchboard, on which are grouped all of the fuses, so that there are no fuses whatever scattered throughout the building.

The whole of the work has been carried out by Messrs. Geipel and Lange, who are agents for Messrs. Thos. Richardson and Sons, while Messrs. Fuller have been advised throughout by their consulting engineer, Mr. A. H. Howard.

CORRESPONDENCE.

THE BRIGHTON BREAKDOWN.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : I have to thank both Dr. Fleming and Mr. Philip for the explanations which they have been good enough to give of the results following the short circuit of a shunt-wound dynamo, but I am sorry that I cannot fully agree with either of them as to the proposed remedies. Dr. Fleming seems to have overlooked the fact that the first case mentioned in my previous letter was one in which separate shunt-wound exciters were used, and that the result of a severe short circuit was that both dynamo field and exciter field were either demagnetised or reversed.

It would appear to be beyond doubt that the primary effect of a sudden heavy increase of current in the armature tends in the first place to demagnetise or overpower the field, and in the second place, by the withdrawal of lines of force from the field, to induce a current in that field, in the same direction as the normal, but, since the field is now a source of E.M.F., of opposite terminal polarity. Fig. 1 is a diagram, based upon Dr. Fleming's, but extended to show the circuits of a separate exciter, with the direction of the currents marked by arrows. Fig. 2 shows the circuits, as I read them, during an external short circuit, and which should, of course, be taken as superimposed by the oscillating currents which Dr. Fleming mentions. It will be seen that, while the momentary induced current tends to strengthen the dynamo field, it is reversing that of the exciter field, the exciter being in this case shunt-wound. Following the rupture of the short circuit, we have an induced current in the dynamo field, reversed in direction from the normal. This induced current, other things apart, tends to remagnetise

Digitized by Google

the exciter field in the original direction, but reversing the direction of current in its armature (*see* Fig. 3). With series-wound exciters this last induced current would reversely magnetise the field, and also reverse the direction of current in its armature (Fig. 4).

This is my difficulty—trying to find a remedy for the effect, of induced field current by elongating the inductive chain, by increasing the number of its links. To me it seems that, if there is any remedy, it is to be found by destroying these links, not adding to them. Obviously, if this be the cases the source of E.M.F. for the excitation of our dynamo fields must be of a non-magnetic character. To couple these fields to the 'bus bars is simply to link them together; to couple them to one set of storage cells is also to link them together. Therefore, I would suggest, with all deference, that it would be better if these fields were separately connected to independent non-magnetic sources of E.M.F. That this would not prevent the demagnetisation, or even reversal momentarily, of the fields I am quite prepared to admit, but the power of recovery given and the raising of the current value necessary for demagnetisation would, I think, practically effect a remedy. As to whethe: such a method will be adopted in central stations I have very little hope. For my own part I am prepared to leave things as they are and risk it!

Mr. Philip asks as to whether a case of the generation of a pulsating current by an armature earth is one of actual observation or not. About three years ago such a case did happen,

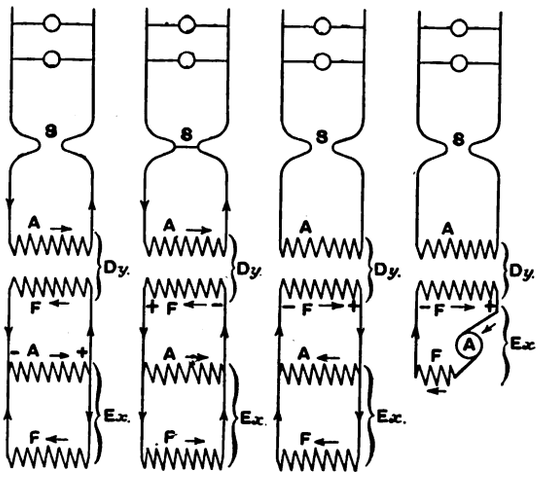

Fig. 1. Fig. 2. Fig. 3. Fig. 4.

and at the Brighton Works. My attention was called to a very visible pulsation in the lighting of the lamps connected to the supply, and also to the fact that the neutral earthing fuse had blown. Parenthetically, I may say that the earthing of the neutral was effected in the following manner:—A connection was made to the neutral main through a lamp to earth, the terminals of the lamp being short-circuited by a fuse of about 20 amperes capacity. It will be seen that an earth on either of the outer poles would blow this fuse and light the lamp. I immediately went to the engine room and saw that the pulsation, which was visible in the ordinary lamps, was much more marked in this earth signal lamp. A consideration of the conditions will show that the branch containing this lamp was being subjected to an alternating current of low periodicity. With eye to the lamp and ear to the engines, I traversed the engine room until I found the engine whose speed synchronised with the pulsation of light in the lamp. It was then withdrawn from the circuit and, on testing, an earth was found in the armature. I may say that the minimum cut-out did not act in this instance.

I am afraid that Mr. Philip's suggestion as to insulating the dynamo is not a very feasible one, certainly not with direct-driven sets such as are now almost invariably used.—Yours, &c.,

Robt. C. Quin.

Blackpool, Dec. 12, 1898.

LEGAL INTELLIGENCE.

Savory v. Edward Lloyd (Limited).

(*Continued from p. 240, Dec. 9*).

The further hearing of this action was continued before Mr. Justice Day and a special jury on Friday last.

Mr. J. B. BRAITHWAITE, Jun., re-examined by Sir E. Clarke, said: In handing over the contract with the Commissioners of Sewers the Brush Company obtained a contract to do such works for the new City of London Company as were within its scope. The Pioneer Company paid the Brush Company £21,750 for works completed. It was impossible to bring out a company with the capital of the City of London Electric Lighting Co. without large preliminary expenses. The difficulty of placing capital at that time was very great. His firm and another each found £50,000 towards the required capital to enable the company to go to allotment.

Alderman F. GREEN said that in Feb., 1890, he was elected chairman of the Commission of Sewers. The contract of May, 1890, was considered to be in the best interests of the ratepayers. Plaintiff had nothing to do with the matter. There was no influence brought to bear upon the Commissioners with regard to the transfer of the Brush Company's contract. He first heard that plaintiff had made a profit in connection with the formation of the Pioneer Company in court the previous day.

Mr. W. H. PANNELL said he had been a member of the Corporation of the City of London since 1874. His firm were employed to audit the accounts of a great many companies, including the Pioneer and City of London Companies. He had, apart from that, no interest in any of the companies of any kind. His only interest was that the City of London should be well lighted.

Mr. W. BROWN, a member of the Commission of Sewers, said that he sold 20 shares in the Pioneer Company as soon as he became a Commissioner at an actual profit of £32. Until he had disposed of them he took no active part in the proceedings of the Commission.

Mr. J. L. SAYER, member of the Corporation and chairman of the Streets committee in 1891, also said he considered the contracts entered into by the Commission of Sewers were advantageous to the ratepayers. As a member of the Streets committee he was a party to the making of the contracts. He had taken an immense amount of trouble in the matter of the electric lighting. The contract for the public electric lighting was extremely favourable to the authorities, although the private lighting might not be quite so cheap.

Mr. MacGEAGH said he was a member of the Commission of Sewers. The plaintiff in this action had nothing to do with electric lighting. He, personally, held some shares in the City of London Company, but did not vote with regard to electric lighting while he held a single Pioneer share.

Mr. C. E. SMITH, a member of the Commission of Sewers and of the Streets committee in 1891, said the plaintiff had never communicated with him in any way with regard to electric lighting. He applied for 25 shares in the City of London Company, and was alloted five only. He only held them a week. He could not say that he quite approved of the then Lord Mayor having made a profit on his electric lighting shares.

This closed the plaintiff's case.

Mr. ROBERT DONALD was then called. He said he was the editor of *London* and the writer of the article complained of. He saw the circular of Mr. Brooke-Hitching and the report of the E'ectric and General Investment Co. He then made independent inquiries and wrote the article. He had no personal knowledge of or ill-will towards the plaintiff. By "monopolistic rights" he meant the Pioneer Company, which extinguished competition in 1891. That monopoly was created by several members of the Corporation. The Streets committee managed the matter. In 1890 only one person named in the article was on that committee. In 1891 Messrs. Walter Brown, Smith and Pannell were on the committee. Witness did not impute dishonesty to these three gentlemen. He imputed wrong, not personal dishonesty. He maintained that their action was against a high standard of municipal honesty. He knew they did not vote or take part in the discussion, but they were present when the Commissioners of Sewers discussed the question. He did not know if they were present when the Streets committee discussed it. Witness charged Mr. Pannell with becoming auditor of both companies while he was a member of the committee which had to deal with the companies on behalf of the City. He held that a man elected as a commissioner did not fulfil his duty by abstaining from voting.

Mr. CARSON, Q.C., for the defence, said the point of the charge was that a Lord Mayor of London had become a promoter of these two companies, and had used his official position to make private gains for himself and his family and friends. Defendant had, in writing the article complained of, first set out the facts of the case absolutely truly. He had then proceeded to draw his conclusions. Whether those conclusions were wrong, the public, having all the facts before them, could judge. It could not be denied that the price charged by the City of London Company for current had been too high, for the £10 shares were now worth £22 to £24 each. That showed that the ratepayers' interests had been sacrified to the shareholders. Mr. Brooke-Hitching proposed a scheme by which the Corporation should buy out the monopoly. The difficulty of the matter arose from the way in which the Company's £1,200,000 of capital had been increased, by the prices charged for lighting, to £2,500,000. The defendants had acted in the public interest, and not out of spite towards the plaintiff, and after due investigation. The charges were that the Corporation created a monopoly and that the then Lord Mayor became a promoter of that monopoly and obtained private gain for himself and his family therefrom. That was a state of things upon which comment could hardly be too severe. Mr. Braithwaite, jun., had told the jury that when the Brush Company tendered for the contract there was no intention of

Digitized by Google

the company carrying it out. It was intended to part with it to the Pioneer Company, and to so make additional profits. In November, 1890, plaintiff became Lord Mayor, and *ex officio* member and chairman of the Commission of Sewers, and of every sub-committee appointed by the Commission. He was, therefore, actually chairman of the Streets committee. The Brush Company had among its directors Mr. J. B. Braithwaite, jun., and the Duke of Marlborough. The City of London Electric Lighting Company was brought into existence merely to carry out a contract which they had no power to investigate. The Electric and General Investment Co. was formed to finance the Pioneer Company. Mr. Braithwaite and the Duke of Marlborough were directors of that company also. In both capacities they refused to take the risk of advancing the sum needed in February, 1891, to carry on the lighting scheme. So they made themselves into a third company—the Pioneer Company—and the defendants alleged and would stand to it that the Pioneer Company was only formed to make money for the Savorys and the Braithwaites. The three companies meant three sets of fees for directors and brokers; and shareholders in the Pioneer Company who advanced their money for six months got it back with 50 per cent. interest. The Pioneer Company was a sham, and it was for the jury to say whether the Lord Mayor of London ought to have appeared on the prospectus of such a company, and also whether he and all his family ought to have made 50 per cent. out of such a company. Contracts were made between all these companies. Mr. Braithwaite and the Duke of Marlborough, as one company, made agreements with the Duke of Marlborough and Mr. Braithwaite as another, and in each case commissions were paid. £25,000 was paid to the Electric and General Investment Co. for negotiating a contract for the Brush Company and the Laing, Wharton and Down Co. The plaintiff never looked into these matters, and never made any inquiries before appearing on the prospectus of the Pioneer Company. Negotiations followed between the Sewers Commission, of which the Lord Mayor was chairman, and the Pioneer Company, of which the Lord Mayor was chairman. How was it possible for the plaintiff to do his duty to both sides? If the Press was to be gagged when it commented on an affair like this, they would soon see the profits growing larger. Then came the City of London Electric Lighting Co., with the Duke of Marlborough and Mr. Braithwaite on the board. It was said all this was rendered necessary by the Baring crisis. Why? The Barings were not electrical engineers. It was also said that at that time the future of electric lighting was very uncertain. That was not the story that appeared in the prospectus. In the prospectus there were stories of magnificent profits, and the profits had since been actually made. Those were the facts, and yet the plaintiff complained of the comments made upon those facts. The comment in the article complained of was fair and honest, and he disclaimed any desire to attack Sir Joseph Savory, and suggested that he might have been the dupe of Mr. Braithwaite. But if that was so he must take the consequences.

Sir EDWARD CLARKE, Q.C., replying for plaintiff, contended that definite accusations of shameful transactions had been made against plaintiff. The evidence that had been given ought to satisfy every one inside or outside the court that nothing had gone on of which Sir Joseph Savory need be ashamed. It had been shown that Sir Joseph had taken no part in the giving of the contracts for electric lighting in the City. The plaintiff was not a member of the Streets committee or of the Sewers Commission in any but a technical sense. No Lord Mayor ever attended the Sewers Commission more than once or the Streets committee at all. In 1890, after 20 years of consideration, a scheme was arranged by which, for electric lighting purposes, the City was divided into three parts. In each of these areas one company had a monopoly upon terms approved and adopted in May, 1890, and which had continued ever since. It was not until months after this approval had been given that the plaintiff became even a nominal member of the Sewers Commission. The accusation now made was that the plaintiff had caused the City to pay too highly for its light. But, as a fact, the City was very well and very cheaply lighted, at least, so far as the public lighting was concerned. In February, 1891, the contracts with the Brush and the L.W. and D. Companies were on the point of breaking down, and that would have meant the indefinite postponement of the scheme. It was to prevent this that the Pioneer Company was founded, and that the plaintiff, as Lord Mayor, came forward. A report of the Sewers Commission in 1889 had recommended the lighting of the City by one large company rather than several small ones, and it was with this object that the Pioneer Company was founded. At the time it was impossible to bring out a large company, owing to the Baring crisis, which upset the whole life of the City, and the Pioneer Company was necessary to pave the way for the flotation of a larger company. The plaintiff's action throughout was for the benefit of the City. His action was public, and might have been attacked at the time, but no one had said a word against it for seven years. As to what had been said about the series of companies, of course it might be wrong for one company to promote another where such an arrangement was a cover for fraud. But in this case there was no allegation that anyone had made an illegitimate profit. The sums paid by the Brush and L. W. and D. Companies to the Electric and General Investment Co. were only their shares of the expenses of promoting the single large company. Mr. Brathwaite had done nothing which could in any way be objected to. He was a connexion of the plaintiff's and acted for various members of the Savory family. There was nothing in the evidence to support the charges of corruption made against plaintiff.

His LORDSHIP said the question was whether the statements made were true, and whether the comments on those statements were fair and without malice. On the evidence it was clear that there could be no foundation for any charge of corruption against the plaintiff, although he might have been indiscreet. On the other hand, there seemed no ground for suggesting that the defendants had any personal ill-will against the plaintiff. It seemed that plaintiff had been indiscreet in joining the Pioneer Company. The matter was one with which plaintiff had nothing whatever to do. It was said that he only joined under pressure; but it appeared that the pressure was exerted by two persons who could hardly be of much consequence in the City—Mr. J. B. Braithwaite, jun., and the Duke of Marlborough. If the charges made by defendants were unfounded they had acted in a very reckless way. It was for the jury to say whether these charges were true.

The jury, after a short consultation, found for the defendants.

Electric Construction Co. v. Imperial Tramways Co.

This case came before Mr. Justice Stirling on the 9th inst., on a motion by plaintiffs for an interim injunction restraining the defendants from the alleged infringement of a patent.

Mr. BOUSFIELD, Q.C., said he supposed defendants had hardly had time to prepare answers to the affidavits which had been filed, and were not, therefore, in a position to proceed with the motion. It was, however, a matter of some urgency, as plaintiff's patent expired in August next.

Mr. WALTER (for defendants): His clients were running a line of tramways between Stockton and Middlesbro' and Thornaby, which was a public tramway, and it could not be suggested that they were going to run away, or that they had not plenty of funds. They were perfectly willing to keep an account. The matter in question related to an unfought patent, and his instructions were that other companies had been doing for years the same as the defendants were doing.

His LORDSHIP: Well, that is a question of laches.

Mr. WALTER: Defendants had not been working publicly for more than four months.

Mr. BOUSFIELD: It is a case of absolute infringement, about which there is no doubt whatever.

Mr. WALTER: My instructions are that there is no infringement.

His LORDSHIP: This is a case in which it would be right to expedite the trial, and I order the motion to stand over till 16th inst.

National Telephone Co. (Limited) v. Commissioners of Inland Revenue.

This case came before the Court of Appeal on the 9th inst., as an appeal by the National Company from the decision on a case stated by the Commissioners of Inland Revenue under Section 13 of the Stamp Act, 1891. In February, 1897, an instrument was presented on behalf of the Company to the Commissioners for the opinion of the Commissioners as to the stamp duty chargeable. The instrument was headed: "The South of England Telephone Co. (Limited)," and ran as follows:—"March 9, 1896: The undersigned hereby agrees with the South of England Telephone Co. (Limited) (subject to above conditions) to pay them the sum of £12 per annum yearly in advance, the first payment to be made on the first day of the month succeeding that in which the wire and apparatus are fixed on the premises of the undersigned, and each subsequent payment to be made on the corresponding day in each and every following year, for the use of a private wire between No. 155, North-street, and the South of England Telephone Co.'s local exchange system in Brighton. Either the company or the lessee may put an end to this agreement by giving to the other three calendar months' notice in writing expiring on the day previous to the rent being due in any year. No verbal notice can be recognised. N.B.—All rentals are payable yearly in advance, and the first year's rent becomes due on the first day of the month succeeding that in which the wire and apparatus are fixed on the premises of the renter." The conditions and covenants entered into between the Telephone Company and the renter were not material to the present issue. The South of England Telephone Co. had been united with the National Company. The Commissioners decided that the instrument was chargeable with the duty of 7s. 6d., and the Court in the previous action affirmed the decision of the Commissioners. Hence the present appeal by the Telephone Company.

Their Lordships now held that the document in question was a contract in writing, whereby an obligation was undertaken to pay a sum of money at stated periods for an indefinite period, and so liable to the duty of 7s. 6d. They, therefore, dismissed the appeal with costs.

CITY OF LONDON CORPORATION AND ELECTRIC LIGHTING.

At the Guildhall yesterday the members of the Court of Common Council were, under the presidency of the Lord Mayor, engaged for some time in discussing a petition presented by Mr. E. Lee, on behalf of the Charing Cross and Strand Electricity Supply Corporation, setting out that the Corporation were desirous of supplying electrical energy within the City areas. The petition bore 5,000 signatures. The views of the petitioners were expressed in the following terms?—

1. That monopoly of supply by any one company is adverse to the interests of the ratepayers and the public.

2. That the rate charged for supply of electric energy by the Corporation is very considerably less than that charged within the City by the present Supply Co.

3. That the service of the Corporation is a more economical, steady and efficient service.

4. That the low-tension distributing system is a safer system for many reasons, among others the avoidance of fireproof transformer rooms or apparatus on the premises supplied with energy.

5. That the low-tension direct current system appears *inter alia* to be the best adapted for arc lighting and motive power purposes.

Digitized by Google

Mr. E. WILMOT SEALE (Secretary of the Company) acted as spokesman of the deputation.

Mr. Deputy SAYER: Do the company undertake to give an electric supply for less than 2½d. per unit?—We do not propose to do so.

Mr. T. H. ELLIS: What is the object of your wishing to enter the City? Is it for the purpose of extending your business?—Yes, but this petition is that the memorial should be placed upon the records of this Court.

Mr. T. H. BROOKE-HITCHING: Is not the chief reason to make a profit for the shareholders out of the pockets of the citizens?—I want the reason clearly stated. Of course, such a reason does enter into our calculation, as we do not pose as philanthropists, but we are perfectly certain that if we came into the City the ratepayers will not regret it.

Are you aware that there are 7,000 consumers of the light in the City?—Yes, and I can imagine that there will be 30,000 when we come in.

How can you account for the fact that out of 7,000 consumers you have secured only 5,000 signatures?—We did not attempt to get the name of every consumer, but if time permitted we might have obtained a great many more signatures.

Mr. J. H. LILE: By placing this petition upon our records, shall we stand in a worse position afterwards?

The TOWN CLERK: A record of what takes place here to-day will, of course, be taken. The fact that the petition was received must be recorded.

Sir ALBERT ALTMAN: What is the difference between the price of the public and the private lighting in your district?—In St. Martin's in the Strand the price ranges from 6d. per unit to 4d. for lighting, and 3d. to 2d. for motive power. If we came into the City it would be proposed to charge a maximum of 5d. for private lighting, and a minimum of 4d. and 3d. to 2d. for motive power.

Mr. M. WALLACE: Assuming that the Corporation becomes in the future the lighting authority of the City, would you regard it as an act of bad faith?—Certainly not. There might be a sentimental reason, but we should not regard it as an act of bad faith.

Mr. H. T. GORDON: You are aware, I suppose, that there are other public electric lighting companies applying to this body? There are the Smithfield Markets and Metropolitan companies.—Yes, that is so.

Mr. A. C. MORTON: Do you present these signatures from persons who are dissatisfied with their present supply?—That is so, undoubtedly.

And you would agree to any conditions for the protection of the citizens?—Certainly, any reasonable conditions that might be proposed.

Mr. E. LEE said he never remembered having presented a more representative petition, and he moved that the petition be placed on the records of the Court.

Mr. MORTON asked Mr. Lee if he would amend his motion so that the petition should go to the Streets Committee.

Mr. LEE: Certainly.

Mr. MORTON then seconded the motion. He had never known a more important petition to be presented. Within the last four or five days circumstances had occurred which had entirely changed matters. He referred to the verdict of the jury in a recent case. That verdict, he said, had entirely altered the position, and it was one great reason why the memorial should be referred to the Streets committee. The Corporation was now practically free to give its consent to competing companies. Mr. Morton then read clause 42 of the City of London Sewers Act, 1848, and said it was clear under that clause that no member of the late Commission should have been interested directly or indirectly in the undertaking, or furnish materials or labour for carrying it out, while for each offence a member was liable to a fine of £100. He had heard a member of that Court swear in a witness box within the last few days that he was interested to the extent of £600, and according to the City Sewers Act the contracts which the late Commission had entered into were null and void. Mr. Morton said he thanked the jury to which he had referred and the Royal Courts of Justice for having released the Corporation from the captivity it entered into in 1891.

Mr. BROOKE-HITCHING said whether the Corporation was able to invalidate its agreement with the City of London Electric Lighting Co. he could not say, but he wished it could do so honestly. He hoped that one of these days the Corporation would itself become the lighting authority of the City. He objected, however, to the Corporation, after placing themselves in the hands of one public company (and escaping, perhaps) running into the arms of another. The memorial, he said, had nothing whatever to do with the Corporation, but was a matter for the Board of Trade; but the fact was that the company in question was trying to push itself in front of two other companies which had offered equally good terms.

Mr. WALLACE expressed a hope that the action of the Corporation would clearly indicate a change of policy, and that the members would hesitate before they handed over the interests of the ratepayers to a public company.

Mr. PANNELL, in supporting the motion, declared that the greater the inquiry was and the wider the publication of the past, present and future action of the Corporation the better it would be for all concerned. He reminded the members that in 14 years' time the Corporation would be able, under the existing agreement, to take over the private lighting of the City.

The motion was carried by a large majority.

The following is the text of c. 42, 11 and 12 Vic., referred to by Mr. Morton in the above discussion:—

"Provided also, and be it enacted, that no person, being a Commissioner, or a member of the Court of Aldermen, or of the Common Council of the City, shall be directly or indirectly interested or concerned in any contract which shall be made or entered into by or on behalf of the Commissioners for the execution of any works by this Act directed or authorised to be done or executed, or for furnishing materials or labour, or for any other matter or thing whatsoever, upon pain that every such contract shall be null and void, and that the person who, being a Commissioner, or a member of the said Court of Aldermen or of the Common Council, shall be so interested or concerned therein, shall for every such offence forfeit and pay the sum of one hundred pounds to any person who shall sue for the same, to be recovered in any of the Superior Courts by action of debt or on the case."

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

NEW BOOKS AND EDITIONS.

The following New Books and Editions can be obtained of the Booksellers or direct from the Publishing Offices, 1, 2 and 3, Salisbury-court, Fleet-street, London:—

NOW READY.

"ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS."—By J. Elton Young, M.I.E.E. The scope of the book aims at furnishing a fuller treatment of the subject, from the standpoint of the Telegraph Engineer, than it has hitherto received, whilst it endeavours to facilitate a thorough comprehension of the theory of testing as applied to electrical lines in general. The Author hopes that, besides Telegraph and Telephone Engineers, it may, perhaps, also prove of service to those in charge of cables for the transmission of light and power. The localisation of faults has been very fully investigated, including the different degrees in which the various methods are affected by the presence of a second fault or of general leakage.—*Extract from Preface.* Demy 8vo, fully illustrated. 10s. 6d., post free; abroad 11s.

"SUBMARINE CABLE-LAYING AND REPAIRING."—By H. D. Wilkinson, M.I.E.E., &c., fully illustrated; price 12s. 6d.

"THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING."—A new work by Messrs. H. K. C. Fisher and J. C. H. Darby, with the above title, is now ready, price 6s. net; abroad, 6s. 3d. This work is intended to serve as a guide to operators already in the telegraph service, and to those who desire to enter that service. The great cable companies now insist that their operators and probationers shall pass certain examinations in electrical subjects. The book is very fully illustrated. *Second Edition now ready.*

"PRACTICAL NOTES FOR ELECTRICAL STUDENTS."—By Messrs. A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free.

"ELECTRO-CHEMISTRY."—By Dr. G. Gore. Third Edition. Price 2s., post free.

"ELECTRIC MOTIVE POWER," by Albion T. Snell, contains the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d., post free; abroad, 11s.

"WIRELESS TELEGRAPHY: SIGNALLING ACROSS SPACE WITHOUT WIRES BY ELECTRIC WAVES."—By Dr. O. J. Lodge, with many original illustrations. *Enlarged Edition*, 2s. 6d. net, 2s. 9d. post free.

"LABORATORY NOTES AND FORMS."—With the above title we have ready the New Edition of a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators and Students. The object of this series is the saving of the time of the Teacher and his Assistants, and to serve as a record of the work done by the Student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen net; in sets of any three, 1s. net; or the set of Twenty (Elementary or Advanced) Exercises can be obtained, price 5s. 6d. net. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. net; or in handy portfolio, price 12s. net; or bound in strong cloth case, price 12s. 6d. net. Strong portfolios can be had, price 1s. each.

NOW READY.—The cheaper edition of Dr. J. A. Fleming's "Electrical Laboratory Notes and Forms." These cheaper Forms have been prepared for the use of students and teachers at the Polytechnic and other science classes throughout the country. The demand for the original set of these Notes and Forms has led to a request for a cheaper set for use at the day and evening classes at many of the technical institutes. These new Forms, which differ only from the higher-priced set in being printed on smaller and cheaper paper and with less space for tabulated records, are issued at half the price of the original set.

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready. Price 7s. 6d.; abroad, 8s.

"THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS."—Edited and enlarged by W. Worby Beaumont. Price 3s. 6d., post free.

"The Electrician" Electrical Trades' Directory and Handbook.—An important announcement in connection with the 1899 issue of the "Big Blue Book" will be found in an advertisement on another page of the present issue, to which our readers will please refer.

TENDERS INVITED.

As will be seen from an advertisement, the Corporation of *Sunderland* require tenders for the supply of three 125 kilowatt, direct current, high speed, steam dynamos. Specifications, &c., may be obtained from the borough electrical engineer (Mr. J. F. C. Snell), Dunning-street, Sunderland. Tenders, addressed to chairman of Lighting committee, Town Hall, Sunderland, to the office of the town clerk (Mr. Fras. M. Bowey), by noon of Friday, 30th inst.

Digitized by Google

As announced in our advertisement columns the *Glasgow* Corporation invite tenders for providing and erecting generating plant at one or other of their new electricity works, including two 200 I.H P., two 400 I.H.P., three 1,100 I.H.P. and two 2,200 I H.P. engines, with dynamos and condensing plant. Copies of specification, &c., may be obtained from the city electrical engineer (Mr. W. A. Chamen), 75, Waterloo-street, and tenders must be lodged with the town clerk (Sir J. D. Marwick), City Chambers, Glasgow, by Tuesday, Jan. 3.

The *Leeds* City Council require tenders for the supply of underground conductors, switchboards, &c., in connection with the extension of their electric tramways. Additional particulars are given in an advertisement elsewhere. Plans and specifications may be obtained from the city engineer, Municipal Buildings, Leeds, or from Messrs. Hopkinson and Talbot, 26, Victoria-street, Westminster, S.W. Tenders, addressed to the town clerk, must be in by 10 a.m. of the 29th inst.

The Corporation of *Dublin* invites tenders for the supply of a high-tension single pole switchboard. Copies of the specification, &c., can be obtained after to-day (Friday) of the city engineer, City Hall, Dublin, and the specification and drawings can be seen at, but not obtained from, the office of Prof. A. B. W. Kennedy, 17, Victoria-street, Westminster, London. Tenders have to be sent in to the town clerk, Mr. Henry Campbell, City Hall, Dublin, not later than 10 a.m. of Wednesday, 28th inst. An advertisement elsewhere contains some further particulars.

The Committee of Visitors of the *Cumberland* and *Westmoreland* Asylum invite tenders for the supply and erection of an electric tell-tale clock, with 30 stations. Further particulars can be had from the Medical Superintendent and tenders must be sent in to the Committee, Garlands Asylum, Carlisle, not later than 2nd Jan. next. Some further particulars are given in an advertisement.

The Corporation of *Burnley* invite tenders for the supply and delivery of underground cables. Specifications, &c., may be obtained from the borough electrical engineer (Mr. W. R. Wright). Tenders to the chairman of the Electricity Supply committee, Town Hall, Burnley, by Tuesday, Jan. 10. Further particulars are set out in an advertisement elsewhere.

The *Edinburgh* City Council require tenders for the supply of switchboards and boosters for their Macdonald-road electricity station. Copies of specifications, &c., can be obtained from the resident engineer (Mr. F. Newington), Dewar-place. Specifications and drawings may be seen at, but not obtained from, the office of Prof. A. B. Kennedy, 17, Victoria-street, London, S.W. Tenders to the town clerk (Mr. Thomas Hunter, W.S.), City Chambers, Edinburgh, by Jan. 2. Further particulars are given in an advertisement elsewhere.

The *Londonderry* Corporation require tenders for arc lamp globes and carbons for the year ending Dec. 31, 1899. Further particulars may be obtained from the city electrical engineer (Mr. R. V. Macroy), and tenders must be sent to the town clerk (Sir R. N. Chambers, Kt.), Guildhall, Londonderry, by 30th inst. See also advertisement.

The Commissioners of the Burgh of *Stirling* invite tenders for the following :—(1) Lancashire boilers, with mechanical stokers ; (2) engines, dynamos, pumps, steam pipes, &c., Green's economiser and tools ; (3) storage batteries ; (4) switchboard and boosters ; and (5) arc lamps. Tenders to town clerk (Mr. Thomas L. Galbraith) by Jan. 2.

Hull Corporation require tenders for pipes and fittings for power station and condensing main from dock ; builder's works for two car sheds, &c. ; steel roof trusses, columns, &c., for sheds. Tenders to chairman Works committee by 30th inst.

The Yorkshire Bacon Curing Co. (Limited), Selby, Yorks., require tenders for the supply of accumulators. Particulars from the manager (Mr. J. E. Prossor).

The Baths committee of the *Manchester* Corporation invite tenders for the electric lighting of the Osborne-street and Gorton Baths. Tenders to the chairman by Dec. 21.

The Electric Lighting committee of the *Dublin* Corporation also invite tenders for constructing transformer sub-stations. Tenders to chairman, City Hall, Dublin, by 21st inst.

The *Shanghai* Council invite tenders for a concession, for a period of thirty years, for the exclusive right of establishing and working a telephone system in Shanghai. Particulars may be obtained of Messrs. John Pook and Co., 8, Jeffrey's-square, London, E.C. Tenders to the secretary (Mr. J. O. P. Bland), Shanghai, by noon of Friday, March 31.

The *Shanghai* Council also invite tenders for a concession for constructing and working about 23 miles of electric tramways on the trolley system. Particulars from Messrs. John Pook and Co., 8, Jeffrey's-square, London, E.C. Tenders to Mr. J. O. P. Bland, secretary, by noon of Wednesday, March 15, 1899.

TENDERS RECEIVED AND ACCEPTED.

The tender of Messrs. Siemens Bros. and Co. for the supply of two steam dynamos at £4,150 has been accepted by the *Bradford* Corporation.

The tender of Messrs. Reunert and Lenz has been accepted by the *Kimberley* (South Africa) Town Council for lighting business establishments and private houses electrically.

The *Liverpool* Corporation have accepted the tender of Messrs. Willans and Robinson for the supply and delivery of four sets of plant similar to those on order for the Pumpfields station at £6,939 per set, less 2½ per cent.

The *Burton-on-Trent* Town Council have accepted the tender of Messrs. John Fowler and Co. (Leeds) for the supply and erection of a 250 k.w. alternator and engine at £2,965.

The Electric Lighting committee of the *South Shields* Corporation have accepted the tender of Messrs. J. and H. McLaren for the supply of a 1,000 I.H.P. steam engine at £3,900, and that of Messrs. Siemens Bros. and Co. for the supply of a 500 k.w. alternator at £2,735.

The tender of Messrs. Crompton and Co. has been accepted by the *Barrow-in-Furness* Town Council for the supply of 21 arc lamps, columns, &c., at £1,107.

Cheltenham Corporation have accepted the tender of Messrs Nalder Bros. and Thompson for the supply of an accumulator and exciter switchboard at £290.

APPOINTMENTS VACANT AND FILLED.

The Electricity Supply committee of Hull Corporation require a mains superintendent. Further particulars are given in our advertisement columns. Commencing salary £120 per annum, increasing by three annual increments to £150. Applications to the city electrical engineer (Mr. A. S. Barnard), Dagger-lane, Hull, by Wednesday, Dec. 21.

A qualified civil and mechanical engineer is required as works manager. Some particulars are given in an advertisement elsewhere, and applications have to be sent in to A. S. A., c/o Messrs. Street and Co., 30, Cornhill, London, E.C.

The Carlisle Corporation require an assistant engineer for their electricity department. Salary £130 per annum. Also a switchboard attendant and two engine drivers (accustomed to Willans' engines). Further particulars in advertisements elsewhere. Applications to the city electrical engineer (Mr. C. D. Burnett), James-street, Carlisle, by 21st inst.

A firm of electrical engineers require a shop manager, competent to manage 600 or 700 men. Address "Factor," care of J. W. Vickers, 5, Nicholas Lane, London, E C. See advertisement.

An armature winder is required for a permanent engagement. Answers to W. T., *Electrician* Office. See advertisement.

An assistant electrician is required for the outside department of an alternating current supply station. Wages 40s. per week. See advertisement.

An assistant lecturer and demonstrator in physics is required at the University College of South Wales and Monmouthshire. Salary £120 per annum. Applications to the secretary, Cardiff, by Jan. 5.

Mr. S. E. Andrew, second assistant at the Leyton electricity works, has been promoted to the position of chief assistant, vacant by the resignation of Mr. Cummins, and Mr. A. J. Abraham, of Northampton, has been appointed charge engineer.

BUSINESS NOTICES.

Messrs. James and George Battcock Fuller (trading as H. Fuller and Sons), electrical engineers, &c., Crown-street and Upper North-street, Brighton, have dissolved partnership. Mr. G. B. Fuller will continue the business at the Crown-street premises under the old title. Debts by Mr. F. G. Clark, C.A , 56, Ship-street, Brighton.

On Jan. 2 the offices of the Royal Meteorological Society will be removed to Princes Mansions, 70, Victoria-street, Westminster, London, S.W.

Mr. W. M. Mordey has removed from 66 to 82, Victoria-street, (Grosvenor Mansions), Westminster, S.W. Telegraphic address, "Biphase, London" ; telephone number, 292 Westminster.

We are asked to state that Mr. E. H. Johnson is no longer in the service of the British Blahnik Arc Light Co.

BANKRUPTCIES, LIQUIDATIONS, &c.

The summary of affairs in the failure of the Cox-Thermo Electric Co. (Limited) is published, and is a sorry statement. The gross liabilities as regards creditors amounts to £18,269. 4s. 8d., expected to rank £15,011. 15s. 8d., and this sum is an exact estimate of the deficiency, the net assets being put at *nil*. The winding-up order was made on Aug. 3, and the statement of affairs, although lodged on Sept. 29 last by the secretary, has not yet been concurred in by the directors. The company was registered on Feb. 3, 1896, capital £100,000, in £10 shares, to acquire from Mr. H. B. Cox

Digitized by Google

certain patents relating to the direct generation of electricity and heat by means of thermopiles and thermoelectric generators, for which Mr. Cox was to receive £100,000 in fully-paid shares and £4,000 in cash. The vendor was the promoter, and he was assisted in the promotion by Mr. R. W. Wallace, Q.C., who undertook to provide £10,000 for promotion expenses and for working the patents upon the security of Six Per Cent. Debentures charging the whole of the assets of the company. The first directors, appointed by the signatories to the memorandum and articles of association, were Messrs. R. W Wallace, Q.C., J. L. Möeller, J. Brown Martin, and H. B. Cox. Mr. Brown Martin states that he resigned, but there is no record of his resignation in the company's books. The directors have advanced sums amounting to £10,000, for which debentures have been issued as under :—

Isidore Gluckstein	500	Roger William Wallace	2,000
Joseph Brown Martin.....	1,000	Francis J. Webster	500
Julius Möeller	6,000	Total.....	10,000

In addition, the directors have advanced about £625, for which they hold no security. The cash consideration to the vendor was duly paid, and the shares to which he was entitled were issued as follows :—

Signatories	7	R. W. Wallace.....	3,393
H. B. Cox.....	5,000	J. Brown Martin	300
J. Möeller.....	1,200	F. J. Webster	100

In April, 1896, the company acquired freehold premises at St. Albans, but very little actual trading appears to have been done, the company's resources being mainly expended in developing the patents. The works were destroyed by fire in February, 1897. The whole of the property was insured for £1,000 only, and it is estimated that a loss was incurred of over £5,000. In order to reinstate the works, the company borrowed from its bankers £3,000 on the security of the property, and upon the directors personal guarantee for the repayment of the loan. On March 10 last, Mr. Thomas Cooper, St. Albans, was appointed receiver and manager. It is stated that the experiments so far carried out have demonstrated that the expense of production is too great to make the invention a commercial success. The unsecured indebtedness of £5,235. 18s. includes £2,287 stated to be claimed by Mr. H. B. Cox for salary, damages, &c. The secured creditors are the company's bankers. The Official Receiver is liquidator, with the following as a committee of inspection :—Charles S. Madan, 34, Crowther-street, Salford ; Edward C. Carter, "Romeland," St. Albans, Herts ; Robert Stanton, jun., 73, Shoe-lane, London, E.C

Mr. A. H. Crump, a member of the firm of Trehearne, Son and Crump, electrical engineers, 155, Fenchurch-street, E.C., has obtained his discharge in bankruptcy, subject to judgment for £5 being entered against him.

In the bankruptcy of Edward B. Pym, electrical engineer, late of Bar Chambers, Scarborough, the first meeting of creditors will take place on 19th inst. at Bankruptcy-buildings, London, W.C., and the public examination on Jan. 20.

A first and final dividend of 2½d. is payable on 21st inst. at 2, Clement's Inn, London, W.C., in the bankruptcy of E. W. Mayner and F. J. Handford (trading as Mayner, Handford and Co.), electrical and general engineers, James-street, London, and Redhill.

It has been resolved to wind up the Electric Coal-Cutting Contract Corporation (Limited) voluntarily, and Mr. W. T. Goolden, 2, St. Nicholas-buildings, Newcastle-upon-Tyne, has been appointed liquidator.

A meeting of the Esson Motor (Limited) will be held at 8, Old Jewry, London, E.C., on Jan. 17, to receive an account of the winding up.

At a meeting of Chamberlain and Hookham (Limited) on Nov. 23, it was resolved to wind up the company voluntarily for the purpose of reconstruction, and to appoint Mr. J. Brown, of New Bartholomew-street, Birmingham, as liquidator, with authority to consent to the immediate registration of a new company. These resolutions were confirmed at a subsequent meeting on 8th inst.

Plant for Sale.—Two 250 kilowatt direct-current dynamos, particulars of which are set out in an advertisement elsewhere, are offered for sale.

As elsewhere announced, the plant, machinery and stock of electroplating and electric lighting works, in Blackburn, are for sale.

Crompton Price List.—Messrs. Crompton and Co. (Limited) notify that, in consequence of recent improvements and economies effected in the manufacture of some of their standard types of machines, a revised list of prices has been prepared, and can be obtained on application.

"The Model Engineer."—We have received from Messrs. Dawbarn and Ward (Limited) the first volume of "The Model Engineer." This is nicely got up and is very fully illustrated. The journal deals with engineering and electrical subjects, and may be commended to amateurs in these branches of study. The price of the volume is 3s. 6d. nett, and it may be well to note that already the demand is in excess of the supply.

Catalogues, &c.—Two sections of the new catalogue of the Chloride Electrical Storage Syndicate (Limited), of Clifton Junction, Manchester, are to hand, and contain some useful information on the application of electricity for power and lighting to yachts and boats. The illustrations in Section C show several yachts fitted with chloride "R" type cells, and a list of yachts so equipped is given on a subsequent page, and shows that the application of electricity to this class of vessel is slowly but surely attaining popularity. Prices of the different types of cells accompany the list. This section also deals with the application of electricity to gigs or yacht tenders, and the illustrations here include several specimens of this class of boat. Section A deals exclusively with lighting cells for various purposes. The catalogue is well got up, and will when completed (seven sections in all) be a useful volume.

Calendars, &c.—Messrs. Street and Co., 30, Cornhill, E.C., 5, Serle-street, W.C., and 164, Piccadilly, W., London, the well-known advertising contractors, forward an 1899 mounted calendar which forms a useful and ornamental office adjunct.

Railway Diary and Officials' Directory, 1899.—Messrs. McCorquodale and Co. forward the 1899 edition of a very useful Diary and Directory of Railway Officials, and also the Railway Almanac for 1899. The directory contains a list of the railway companies of the country, with the officials and other particulars, together with salaries and interest tables, &c., &c. The price is 1s.

Exports of Electrical Apparatus and Material.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from Dec. 7 to Dec. 13, with the ports of destination :—

Argentina—Buenos Ayres, £736 (including £512 telegraph material) ; Rosario, £613. *Australasia*—Adelaide, £44 ; Auckland, £115 ; Brisbane, £12 ; Launceston, £700 ; Melbourne, £533 ; Otago, £62 ; Sydney, £291. *Belgium*—Brussels, £200 (telegraph material) ; Ostend, £51. *Canada*—Santos, £235. *Ceylon*—Colombo, £83 (including £33 telegraph material). *Denmark*—Copenhagen, £521 (telegraph cable). *France*—Boulogne, £88 ; Dunkirk, £16. *Germany*—Hamburg, £265. *Gibraltar*, £30. *Holland*—Rotterdam, £388 (telegraph material). *India*—Bombay, £140 ; Calcutta, £62 ; Madras, £64. *Japan*—Yokohama, £120. *North Atlantic*—£4,500 (telegraph cable). *Norway*—Christiania, £494 (telegraph material). *Portugal*—Lisbon, £17. *Russia*—Libau, £45 ; Reval, £426 (including £321 telegraph material). *South Africa*—Cape Town, £814 ; Durban, £1,422 (including £1,397 telegraph plant) ; Port Elizabeth, £316 ; Zanzibar, £31. *Straits Settlements*—Penang, £58. *Sweden*—Gothenburg, £308 (telegraph cable) ; Stockholm, £156 (telegraph material). Total, £13,957, against £15,063 in the corresponding week last year (Dec. 8 to Dec. 14).

MUNICIPAL, FOREIGN AND GENERAL NOTES.

American Electrical Consolidations.—Efforts are, it is said, being made to combine the three electric light companies of Baltimore into one corporation. The companies included in the deal are the Brush Electric Co., of Baltimore City ; the Northern Electric Co. and the Edison Electric Illuminating Co.——The negotiations as to the consolidation of the City Passenger Railway Co. and the Consolidated Street Railway Co. will, it is thought, culminate in the purchase of the former by the latter. About £2,400,000 would probably be involved in the deal, and £200,000 or more would be expended in immediate improvements, including the change of some cable lines to electricity.——The certificate of incorporation of the combination of manufacturers of electric elevators and hoisting apparatus has been filed under the name of the Otis Elevator Co. This latter combination is said to include the Otis Elevator Co., the Sprague Elevator Co. and various other elevator interests. The company is capitalised at £2,200,000 ; £900,000 Preferred and £1,300,000 Common stock.

Ayr.—The Town Council on Monday considered a communication from the Drake and Gorham Electric Power and Traction Co. stating that the company might consider the advisability of withdrawing their application to the Light Railway Commissioners for power to construct a light railway from Ayr to Monkton, if the Council were disposed to grant them a lease of the tramways. It was decided not to entertain the proposal.

Bangkok.—Bangkok Electric Light Co. have disposed of the whole of their electric lighting undertaking to Capt. Andersen and Admiral de Richelieu, who, it is understood, will buy out the interest of the Siamese Government in the plant. The new owners will introduce more capital and carry out extensions of the plant and mains.

Beckenham (Kent).—The Board of Trade have deferred the consideration of the revocation of the Council's provisional order for a further period of six months.

Basingstoke.—The Board of Trade have sent a communication to the Town Council stating that "considering the advance which has now been made in electrical science, the Board are of opinion that the time has come when local bodies should apply for pro-

Digitized by Google

visional orders rather than for licences." A provisional order is, therefore, to be applied for.

Birkenhead.—A Local Government Board inquiry was held on Thursday last into the Town Council's application for power to borrow £15,000 for electric light extension purposes. The town clerk (Mr. Alfred Gill) said that the amount would be expended in putting down additional plant at the electricity station, and also in extending the mains within the borough to meet the demand for current. Technical evidence was given by the electrical engineer (Mr. W. Bates). There was no opposition.

Bedworth.—Dissatisfaction is expressed by the Parish Council at the present gas lighting, and inquiries are being made as to cost of electric lighting.

Blackpool.—The General Purposes committee decided this week to adopt the overhead trolley system on the promenade. Mr. R. C. Quin (borough electrical engineer) presented a report in which he stated that the promenade, owing to the frequent incursions of sand and water, was exceedingly ill-adapted for the present system. On fine days the minimum leakage of the line was 45 per cent., and the maximum leakage allowed by the Board of Trade was 2½ per cent. only. The present system was of a ruinous character. The new copper conductors cost £800 a year, repairs to collectors cost £400 a year, while the cost price of leakage electricity was £700 annually. They had lost over £2,000 a year, which the overhead system would prevent.

Blairgowrie (N.B.).—Negotiations have been opened with the proprietors of the proposed source of power for the electricity works (the river Ericht), and as soon as an arrangement is arrived at a company will be formed with a capital of £8,000 or £10,000 to carry out the work. Mr. R. F. Yorke is the consulting engineer.

Canterbury.—The Town Conncil have decided to apply to the Local Government Board for sanction to borrow £12,000 for electric light extensions. The electricity works are not yet open for supply.

Carlisle.—The Town Council have expressed approval of the proposal to adopt the overhead trolley system on the local tramways.

Chelsea (London).—The Vestry have declined the Chelsea Electricity Supply Co.'s recent offer to supply electric current for public lighting.

Chiswick.—A definite agreement has now been arrived at between the Council and the Aberystwith and Chiswick Electricity Supply Co., as to the establishment of electricity supply works.

Christmas Postal Arrangements.—As Christmas Day falls on Sunday this year there will be no delivery of letters in London and its suburbs on that day. There will, however, be a parcels post delivery on Christmas Day in London and generally throughout the United Kingdom.

Death from Electric Shock.—An inquest was held at Southampton on Tuesday into the death of a man named Davies, in the employ of Messrs. W. T. Glover and Co. Deceased, who was at work on the mains being put down for the Corporation, accidentally placed his hand on a live wire and was instantaneously killed. The inquiry was adjourned.

Derby.—The Corporation decided on Wednesday to purchase the local tramways for £32,000. Opposition is to be entered against the bills by the General Power Distributing Co. and the Leicestershire and Warwickshire Electricity Supply Co.

Devonport.—The Town Council are negotiating for the purchase of the market buildings as a site for an electricity generating station.

Doncaster.—The Corporation have resolved to apply to the Light Railway Commissioners for authority to construct a system of electric tramways.

Eastbourne.—At a special meeting on Tuesday, the Town Council confirmed its decision to purchase the undertaking of the Eastbourne Electric Lighting Co., and to apply for a provisional order. The Electric Light Company are willing to sell their undertaking for £132,307. 10s., and the Corporation offer £77,564.

Falkirk.—The Falkirk Central Electric Light Association started the supply of electric current on Friday last. The association is composed of a number of shopkeepers whose premises will be lighted electrically in future. The work has been carried out by Messrs. T. Laurie and Co.

Government Purchase of the Telephones.—We have previously referred to the letters which have appeared in *The Times* from Mr. Edward Rae, who has acted as spokesman for the members of the provincial stock exchanges. Mr. Rae has suggested as the only means of improving the position of matters telephonic that the telephones should be nationalised. This suggestion has drawn from Mr. J. Staats Forbes, President of the National Co., the following letter:—

"Oxford-court, Cannon-street, E.C., Dec. 13.

"Sir: The letters from Mr. Edward Rae appearing in *The Times*, suggesting the advantages which would arise from the absorption of the business and machinery of the National Telephone Co. by the State, have naturally received the most careful consideration and attention of the Board. The Board are sensible of the deficiencies of the present system, but must remark that these are greatly attributable to the want of proper facilities for construction and maintenance of plant; to the insecurity of the present tenure of the company, and to the absence of those favourable conditions which apply to other companies conducting public services under the authority of Parliament. The Board are, and have been, only too anxious to co-operate with the Post Office (as that department can testify) in effecting improvements and development in the business, and if, as seems to be possible, the drift of public opinion should result in the desire to transfer the telephone business to the State they would feel it to be their duty, upon reasonable and fair terms, loyally to co-operate in bringing about the change, and, subject to the responsibility of consulting the shareholders, I am authorised to say, in answer to Mr. Rae's first question, that his proposal, if it should assume a practical shape—that is to say, if the Government should entertain the question of purchase—would form an acceptable basis of negotiation; and to his second, that on the assumption that the business be conducted on commercial principles the future earning capacity from year to year is not overestimated, but, on the contrary, if the restrictions and difficulties now attending the operations of the company be removed, they are largely underestimated."

Greenock.—In a report recently prepared by the burgh electrical engineer (Mr. S. E. Fedden), he estimates the cost of purchasing the tram lines from Rue End-street into Port-Glasgow at £45,000, and the conversion of lines from end of Port-Glasgow to Ashton at £150,800. Should the lines be leased to the existing company, an agreement for the supply of electric current so as to give reasonable profit to the board's electrical department is advised.

Mr. Fedden has also presented a preliminary report on the electric lighting question. The Hunter's-place site has been selected for the generating station. The low-tension continuous-current three-wire system of distribution is recommended, and the total cost of the scheme, which provides for the erection of 40 arcs for public lighting, is estimated at £30,000. If the Council decide to adopt electric traction, current could be supplied to the tramways department by incurring an extra capital expenditure of between £4,000 and £5,000.

Hanley.—The Town Council have accepted Mr. C. J. Sutherland's resignation of his appointment as joint electrical engineer of the Council's electricity department. Mr. Sutherland will commence his duties as city electrical engineer at Worcester on 1st prox.

Herne Bay—Messrs. W. C. Bersey and Co. will apply for a provisional order for this district.

Hyde.—Owing to the Town Council's decision to establish electricity supply works, the application of the Electrical Power Distribution Co. for a provisional order is to be opposed.

Ilkeston.—The Town Council are applying for provisional orders for electric lighting and traction purposes. Last week a report from Mr. Herbert Talbot, on the proposed electric lighting and traction scheme was discussed. The low pressure continuous-current three-wire system of distribution, with a pressure of 500 volts between the outers, was recommended. Mr. Talbot pointed out that by combining the plant for both supply and traction great economy would result, and less spare plant would be needed. He estimated the cost of electric lighting plant, capable of supplying current to the equivalent of 3,000 8 c.p. lamps at one time, and 50 arc lamps for street lighting, with ample reserve plant, at £15,765; and for tramways, including buildings, permanent way, power station, and plant, overhead construction, feeders, and 10 cars with necessary car shed and repairing shop, £64,749.

Infirmary Lighting.—The governors of the Dundee Royal Infirmary have decided to extend their electric lighting installation at a cost of £450. They consider "the advantage of the light was so obvious that it is unnecessary to speak of it, and, as to the annual cost, it is expected that, being large consumers, the bill would not much, if at all, exceed that for gas."

Lambeth (London).—The South London Electric Supply Corporation have submitted to the Vestry a comprehensive scheme for the lighting by arc lamp of the principal streets. The company are bound to supply current for and to maintain 25 arcs free of charge. In addition to this number the company offers to put up 225 arcs and to supply current from five circuits for £22. 10s. per lamp per annum—a total yearly expenditure of £5,062. The present cost of gas lighting is £1,800 for the same streets. The Lighting committee proposes that the company should erect 50 lamps, and charge for the 25 over those to be supplied under the agreement at £20 per lamp per annum. This proposal has been accepted by the company except that they decline to reduce the annual charge from £22. 10s. to £20. The Lighting committee have recommended the Vestry to accept the company's proposal with the lamps alight until 1 a.m., instead of only midnight, but at the last meeting an amendment was adopted adhering to the terms proposed by the Vestry, and instructing the committee to submit particulars of the cost of the arc lamp standards and a comparison of the cost of electric light supplied by meter, against the price which the Corporation or any other similar company would charge.

Digitized by Google

Leeds.—The formal transfer of the electricity undertaking of the Yorkshire House-to-House Electricity Co. to the Corporation took place yesterday (Thursday). The whole of the staff will be taken over by the Corporation.

Leyton.—Sixty arc lamps are to be erected in High-road, Leyton, and High-road, Leytonstone, and application is to be made to the Local Government Board for sanction to borrow £1,350 for carrying out the work. Extensions of the mains for private lighting are also to be carried out.

Light Railways.—At the Board of Trade on Wednesday, Sir Courtenay Boyle, K.C.B., considered the objections to the confirmation of the order made by the Light Railway Commissioners, authorising the London United Tramways (Limited) to construct a light (electric) railway from Hanwell to Uxbridge. Mr. Pope, Q.C., for the objectors (the Great Western Railway Co.), submitted that the Board of Trade should not confirm the order. The object of Parliament when passing the Light Railways Act (which gave the Board of Trade power to confirm such an order without the intervention of Parliament) was not that the machinery should be used to enable the Board of Trade to deal with questions which ought to receive the sanction of Parliament. Mr. Pope said his point was that the effect upon the railway already existing in the district would be of such magnitude that it ought not be dealt with except by a committee of Parliament, and, further that it was not a case in which the powers of the Light Railways Act should be invoked at all —that it was, in point of fact, a tramway extension, and that it ought not to be permitted that the powers and protection which were given to the various interests under the Tramways Act should be evaded by proceeding under this particular form of legislation, which was not really applicable to the present scheme. The Great Western Railway felt that this proposal was of so much moment to their interests, and having regard to the recent adjustment of railways which had been made for the accommodation of the district by Parliament itself, that it was a case which ought to be judged of by Parliament directly and not by the Board of Trade under the Light Railways Act. Mr. Balfour Browne, for the promoters, contended that the evidence had absolutely failed to show there was any such competition as would make the undertaking one which should not be dealt with by the Board of Trade, but one which should go to Parliament. The competition was trivial to a degree, and if such competition as arose in this case was to be a bar to a light railway they would put a stop practically to the Light Railways Act. Decision was reserved.

London County Council.—At Tuesday's meeting the question of the Council allowing the National Telephone Co. to retain certain overhead wires in Islington, the spans of which are of greater length than allowed by the Council's bye-laws, was again considered. The recommendation of the Highways committee was to allow the wires to remain for a certain period. After some discussion the matter was again referred back to the committee till after the Christmas recess. The same committee recommended that the application by the National Company to lay eight additional lines of pipes underground between Northumberland-avenue and the Victoria Embankment subways be granted on certain conditions, one being that a rent of £1. 1s. per annum be paid in respect of each length of pipe. The recommendation was approved.

Mr. Benn (chairman of the Highways committee) read a letter from Mr. Young, of Glasgow, who was recently appointed chief of the Tramway Department, announcing that the duties were very different to what he anticipated, and to what he had been accustomed, and he, therefore, declined the position. It was agreed that the office be left vacant for the time being, but that Mr. Alfred Baker, manager of the Nottingham Corporation tramways, be appointed manager at a salary of £1,000 a year.

London County Council's Tramways.—As will be seen from the above report of the proceedings at Tuesday's meeting of the County Council, Mr. John Young, who was selected for the post of general manager of tramways under the Council, has declined this position. A post has been created which has been offered and, we believe, accepted by Mr. Alfred Baker, tramway engineer to the Nottingham Corporation tramways, the salary being fixed at £1,000 per annum. It is generally conceded that the Highways committee of the County Council have lost just the official who, from his previous experience, was capable of organising the tramways department, but it is to Mr. Baker's credit that he is a young man, only 35 years of age. He began his career as a tram conductor at Nottingham nearly 20 years ago, and from that time to the present has made the development of the Nottingham tramways his life's work. On the acquisition of the tramways by the Nottingham Corporation in 1897, Mr. Baker was taken over, having previously filled the post of manager to the Tramways Company for the previous seven years. At the time of his appointment by the Tramways Company, the finances of the concern were in a low state, the shares were at a heavy discount and shareholders had but little faith in the ultimate success of the Company. All this was speedily changed after Mr. Baker's appointment, and Nottingham now possesses a first-rate municipal tramway service. The original shareholders received the full par value of their holdings on the Corporation taking over the company's undertaking. Mr. Baker's experience, so far, has been confined to horse traction, but he has already advised the Nottingham Corporation on the subject of converting the horse lines into electric lines, and the Nottingham authorities have this matter at the present time under consideration. It is to be hoped that no petty differences will be created necessitating the withdrawal of Mr. Baker in a similar manner to that of Mr. Young, as, if report speaks truly, very little tact on the part of the Highways committee of the London County Council would have obviated Mr. Young's action.

Mansfield.—The Town Council are applying for a provisional order. The initial capital expenditure of electricity works is put at £15,000, but if current were taken "in bulk" from the General Power Distributing Co. the cost is put at only £5,000.

Newcastle-on-Tyne.—The Council have appointed a special committee to consider the question of electricity supply.

New Company.—A notice appeared in our last issue of the registration of the British Schuckert Electric Co. (Limited), which has been formed with a capital of £200,000, the whole of which we learn has been privately subscribed. The company has the valuable technical knowledge and experience of the Electrizitäts Aktiengesellschaft vormals Schuckert and Co., of Nuremburg.

Newport (Isle of Wight).—The Ventnor Electric Light and Power Co. are applying for a provisional order for this town, and, if satisfactory terms can be arranged for the supply of current for public and private lighting, the Town Council will probably approve of the application.

Northallerton (Yorks).—Under the terms of an agreement with the District Council the Northallerton Electric Light and Power Co. agree to erect and maintain two arc lamps in the market-place free of cost. The Council have the right to purchase the company's business, plant, goodwill, &c., upon the following terms:—(*a*) At any time between Jan. 1, 1900, and Jan. 1, 1905, on twelve months' notice, on payment of the sums expended in the erection of the works, plant, &c., and the formation and carrying on of the company, together with such a sum for each year, during which the net profits fall under 5 per cent., as shall make up the 5 per cent. (*b*) On Jan. 1, 1900 (after notice) at a valuation as a going concern and a sum not exceeding 15 per cent, on the amount of such valuation for goodwill. (*c*) On Jan. 1, 1915 (after notice), at a valuation of a going concern and a sum not exceeding 20 per cent. on the amount of such valuation for goodwill. (*d*) At any time after Jan. 1, 1915 (after notice), at a price to be settled by arbitration. So long as the company's works shall be carried on to their reasonable satisfaction the Council shall not erect or give consent to any person or company during the currency of the agreement to erect posts and carry wires overhead, or under the streets for the purpose of supplying electric current for lighting or power. There is no provisional order in this case.

Ogmore and Garw.—The District Council have entered into an agreement with the Ogmore Electric Light Co. for the electric lighting of the district for the year 1899, at £3 per 16 c.p. lamp.

Oldham.—The Electric Lighting committee have decided to consult Prof. Kennedy as to the extension of the electricity works.

The National Telephone Co. have made another unsuccessful application for permission to lay wires underground. The town clerk has expressed the opinion that the object was to enhance the value of the company's plant, which would sooner or later be taken over by the Government, and in that case they would indirectly have to pay their proportion of the cost. Singularly enough, the Finance and General Purposes Committee, at a later meeting, resolved to request the company to establish further call offices.

Police and the Telephone.—The Court of Common Council have referred to the Police committee the question of connecting several of the City police stations with the telephone service.

Power Supply.—The County of London and Brush Provincial Co. are issuing a circular calling attention to the advantages of electricity for power purposes, which calls for the careful attention of all users of mechanical power. The Company offer intending consumers desiring special information as to choice of motors and controlling apparatus therefor, the assistance of their engineering staff. The circular gives particulars as to floor space, &c.; and, in fact, will be found of service to all contemplating the use of electric motors for driving.

Redditch.—The District Council have entered into an arrangement with the National Electric Free Wiring Co. for the "free" wiring of premises in the district.

Rhyl.—The District Council have received a report from Mr. J. L. Owens on the electric lighting question. The initial capital expenditure entailed by the scheme set out would be £16,679.

Richmond (Yorks.).—The Gas and Water committee has been authorised to spend a sum not exceeding £10 for expert advice as to the establishment of electricity works.

Digitized by Google

St. Helens.—The price of electric current has been reduced from 6d. to 4d. per unit.

St. Marylebone (London).—Last night at the Vestry meeting Mr. T. H. Brooke-Hitching moved a resolution that application should be made to Parliament for a special Act to empower the Vestry to erect and maintain electric lines and works, and to supply electricity for public and for private purposes throughout the parish. He said that in the event of the Bill being passed they would be enabled to purchase the interest of the Metropolitan Electric Supply Co. as regards their undertaking in that parish. It was hoped that they would be able to get the company to state the figure they would sell to the Vestry in an amicable manner. Sir E. Galsworthy asked how it was they had abandoned the idea of going for a provisional order. Mr. T. H. Brooke-Hitching said it was known that the Board of Trade would not grant to municipal authorities provisional orders to compete against companies who were doing their duty. Mr. E. White said there was nothing in the notice in regard to buying out the company, although they were told that such was included in the bill promoted. Mr. Brooke-Hitching had told them nothing of what this undertaking would cost. He estimated that the least the company would require for their undertaking was £600,000, which would mean their having to pay for interest, &c., £30,000. The company's profit was only £25,000, so that the Vestry, if they acquired the undertaking, would be losing £5,000. Mr. Sutherland said it was idle to think that if they had the electric lighting under their control they would lose £5,000 a year. Mr. J. Lewis hoped they would not rush this question till they had already seen what it was proposed to do by the Bill. He maintained that the Committee of the House of Commons was wrong in rejecting their application. They were told that the legal costs they had already incurred amounted to £3,000. Mr. G. B. Crook said the Vestry had entered into an agreement not to enter into competition with the Company. He contended that they were in a worse position than they were before they went to the House of Commons for the confirmation of the Board of Trade provisional order. Sir Edwin Galsworthy moved that the subject be adjourned, which was unanimously agreed to.

Sheffield.—The City Council have decided to appoint a special Electric Lighting committee.

Shirebrook (Notts.).—A committee of the District Council has been appointed to consider and report upon the proposal of the Shirebrook Colliery Co. to lay electric lighting mains in the district for the supply of current for public and private lighting.

Shrewsbury.—The Local Government Board have sanctioned the borrowing of £30,000 for the purchase of the undertaking of the Shropshire Electric Light and Power Co. and the extension of the electricity works.

Sleaford (Lincs.).—The District Council have decided to engage a consulting engineer to report upon the question of establishing electricity supply works.

Southport.—The Town Council have expressed approval of the scheme for the construction of an electric tramway between Lytham and Southport. The Council and the British Electric Traction Co. are seeking Parliamentary powers for the construction of electric tramways in the Southport district.

South Shields.—The Town Council have rejected a proposal to increase the salary of the borough electrical engineer (Mr. J. A. Jeckell) from £300 to £350 per annum.

Swansea.—The Town Council have decided to open negotiations with the Swansea and Mumbles Railway Co. with a view to acquiring the railway and introducing electric traction.

Telegraph Poles.—The poles used by the British telegraph department come chiefly from Norway and Sweden. It is stated that the terms of the specifications will be so changed as to admit of tenders from Canadian supply houses. Tenders are to be immediately invited for 25,000 poles.

Telephone Extension.—The National Company are just completing a new exchange at Newquay (Cornwall).

Walsall.—The number of customers of the electricity department on Nov. 30 was 127. The Council will oppose the Bill for the adoption of electric traction on the South Staffordshire lines.

Warwick.—The Town Council are conferring with the Leamington authorities on the proposals of the British Electric Traction Co. to introduce electric traction on the local tramways. The Council have resolved not to allow the use of the overhead trolley system.

Workhouse Lighting.—Tenders are to be invited for the electric lighting of the new Doncaster workhouse.

Wrexham.—A special meeting of the Town Council is to be called to consider the proposals of the Drake and Gorham Electric Power and Traction Co. for the construction of electric tramways in the district.

COMPANIES' MEETINGS AND REPORTS.

West India and Panama Telegraph Co. (Limited).

The forty-third ordinary general meeting of this Company was held on Wednesday. Mr. WILLIAM ANDREWS presided.

Mr. R. T. BROWN (Manager and Secretary) read the notice convening the meeting.

The CHAIRMAN: Gentlemen, I suppose you will, as usual, take the report as read. Agreed. We are rather later this year than usual in presenting our accounts, and we sent to the newspapers, for the information of the shareholders, on Oct. 20th a circular, stating that the delay in holding the meeting was on account of warlike operations, the irregularity of mails and the delay in the correspondence. Well, that is not altogether cured yet. We cannot say that there is an end of these exceptional circumstances. You will have noticed, for instance, in the report that we show an increase of £6,738, but in the accounts, as far as they have since been ascertained, they only show an increase on balance of some £1,400. Of course, the first figures of the receipts is an estimated one that is sent by wire, and the last shows the state of the accounts, as far as we have been enabled to get them completed, and as they actually work out, but I may tell you they are not final. You will remember that there were large tariff reductions made on January 1st, by which the accounts have been a good deal complicated. And then there were, of course, owing to the war, censorship restrictions, messages being frequently deviated by one route or another, and the effect of that has been, of course, that the product has varied more or less. Upon the whole, however, we thought that it was the best plan to take the old figures as being the best available, and to correct, as nearly as we could, when the returns enabled us to do so. For instance, in the beginning of the half-year, the first three months showed a loss of £3,478, consequent upon the considerable reductions of tariff which you will remember we had to make. Well, subsequently that decrease of revenue was turned into an increase, by the operations consequent upon the war, and the number of telegraphic messages which were sent by the belligerents. We found in the end that with the losses on exchange, rebates which we lost or failed to get, and allowances for certain claims which must be made, and which had to be provided against, that the total that we should take credit for would be diminished, and that it would not be the increase which you see in paragraph 3 of the report, but the amount shown in paragraph 1, which is actually adopted. Now you will understand with regard to the increase, as given in the report, that the result cannot be worse than that shown, and we may find ultimately there will be a considerable margin. With regard to expenses, there is not much to state in connection with them; they amount to £21,704, against £21,426, an increase of £278, and I may say that that outlay is largely attendant upon warlike operations which have cost the Company something like £1,000, and, therefore, I think that we may look for an early diminution in the expenses, although, as I have frequently had occasion to say, you cannot expect that there will be any large diminution, because we keep them down as closely as possible in every way. Well, now, gentlemen, I think it is rather a gratifying fact that you will notice that, despite the operations of the fleets, and of the armies, in the Spanish-American war, and the disturbances which took place, the Ponce, San Juan (Porto Rico) and Santiago de Cuba cables and land lines of the Company have all been maintained in good working order, although the damage to the harbour lengths—which is more like an inland sea—at Santiago has not yet been completely repaired. I think it is satisfactory that, in spite of all this, we have been able to carry on our operations. Well now, gentlemen, I come to the receipts estimated for the current half-year, and although they are subject to correction, the same as for the half-year ended June, I think it will be found that they will show a very considerable augmentation compared with 1897. After every allowance has been made in the accounts for exchange, rebates and claims, including our outlay upon repairs consequent upon the hurricane, which has not yet been dealt with in the accounts, the nett receipts, I have every reason to believe, will be eminently satisfactory to the shareholders. I am sorry to have to tell you that during the war troubles we lost our agent and two clerks at Santiago, where they had been working under the most unexampled difficulties, as you may imagine, and I think that in these circumstances the Company may take credit for having kept its lines going under the conditions we have had to contend with. I think it is very gratifying that the Company should have been enabled to go on working well, at such an important international juncture, and that such an amount of celerity should be afforded to those desiring to use the telegraph lines, which have always been kept open by one route or another. And, therefore, under these circumstances of the half-year, I hope that the shareholders will not be altogether dissatisfied with us. Now in regard to the operations of the current half-year (because I feel I have pretty much disposed of the past half-year) I may say that our new cables, in substitution of the old chord line which had failed, have been successfully laid and are in excellent condition, and they go from Grenada to St. Lucia and thence to Ste. Croix, in addition to which we have duplicated the Trinidad-Grenada section. These duplications have greatly strengthened the Company's duplicate system. Now, the Jamaica, St. Lucia Cable touches at present at Porto Rico and Ste. Croix, and I may say to you that without detrimentally affecting the working of the system, or in any way altering its efficiency, we could by the insertion of a short additional length of cable, and the provision of some few additional clerks, have it worked as a direct all-British cable from Jamaica to St. Lucia and all the other British islands. However, we have not thought that it was worth the Company's while to spend more money and to incur increased working expenses to ensure an object for which no demand has been made. Well, now, gentlemen, we have had to contend not only with war, by fleets and by armies, but with an elemental war of a tragic character, which has been no other than the disastrous hurricane visitation that the West Indies have suffered from, causing an appalling loss of life and destruction of property, and unprecedented distress, more especially so in two of the islands. Well, gentlemen, your Directors, feeling sure of the sympathy and support of the shareholders, met together and voted a sum of 250 guineas, as the Company's mite towards the relief of the sufferers from this terrible calamity. The Cuba Company and the International Ocean Co. joined with the West India and Panama Telegraph Co. in an extension of the boon of free messages through their system in connection with the Hurricane Relief Fund for the succour of the people, and thereupon we placed ourselves in communication with the American lines, who immediately agreed to an extension of the boon over their system, and thus free messages were sent the whole distance from London to the West Indies. Here they were of advantage in meeting the circumstances of the case, and I have reason to know that the sympathy of this Company, thus manifested at the earliest possible moment, contributed very much to increasing the facilities of relief afforded. Well, gentlemen, the damage from the hurricane sustained by this Company's lines, both on land and at sea, amounts to a sum which may ultimately be estimated to reach £5,000, which is not an agreeable item; but, as previously stated, the augmented receipts owing to the war will practically prevent the shareholders from feeling the enhanced expenditure—in fact, they will not feel it at all. The British Government has come forward to the aid of the West Indies, and I have no doubt that the assistance thus afforded will enable them to surmount—or very largely assist towards enabling them to surmount—their present distress, and we trust that the assistance thus afforded to the islands which have suffered will later on eventuate in a more substantial measure of success, and enable a permanent return to be made to their former prosperity. I have no doubt that the people will do their best to support the Colonial Secretary in these efforts in regard to the West Indies at this juncture, and if something were not done for the West Indies, I imagine that there would be some odious comparisons. The shareholders are probably aware that Cuba and Porto Rico are now passing into the hands of the United States Government and people, and here I must make a public and grateful acknowledgment of the perfect loyalty with which Spain has always fulfilled her concessional obligations up to the last moment, and the fair and considerate treatment that she has always vouchsafed to this Company. It is also most gratifying to me to be able to state that upon all questions that have arisen with the American Government that the administration has taken sedulous care that the Company should be fairly treated, and they have dealt with the Company's representations, I must say, in a most conciliatory spirit. Of course, gentlemen, we cannot forecast the future. The American Government, no doubt, have great difficulties to contend with in the restoration of order, in the maintaining of good government and the organising of commerce and prosperity in a new country, but our wonderful kindred people across the sea are not given to fail. They possess a fertility, energy and determination which generally find for them a satisfactory way out. Of course, the settled prosperity of Porto Rico would be of great benefit to us, because it is one of our most important places of communication. Well, gentlemen, we owe it to our staff to draw attention to the satisfactory manner in which their duties were discharged throughout the whole system, and especially during the hostilities—when, of course, the business was very largely augmented—and also during the hurricane in the islands especially visited by those misfortunes. We have had a troublous time, and we have done our little best for your interests. I do not know, gentlemen, that there is any more with which I need trouble you upon the present occasion, and, therefore, I will move the resolution, and after it has been seconded, I shall be glad to answer any questions that any shareholder may desire to ask to the best of my ability, and I now beg to move that the report and accounts be adopted, and that the dividends recommended in the report be declared.

Mr. HENRY HOLMES: I beg to second the resolution.

Mr. COPLAND said the report stated that the revenue for the current half-year was also considerably in excess of that for the corresponding period, but was tending gradually to resume its normal limits, and he would like to ask for a little information about the actual figures. He would like also to offer the suggestion of the establishment of a dividend reserve fund, because he was of the opinion that it would enhance the value of the Company's shares in the market very much.

The CHAIRMAN said that the calculation of Mr. Copland was a very accurate one, because, during the current half-year, they had gross receipts amounting to £48,165, against £18,032 during the corresponding half of last year, or an increase of a little better than £30,000 or 166 per cent. In the report they shewed an increase of £6,700, and, of course, there would be a considerably larger sum for the current half-year available for distribution than it had been their fortune to deal with on previous occasions. There should be a big balance. He thought the suggestion of Mr. Copland for the formation of a dividend equalisation fund was a very good one, and a very sensible one.

Mr. SAUNDERS asked the Chairman whether they had any connection with the Western and Brazilian Telegraph Co.'s system, which he understood had amalgamated with the Brazilian Submarine? He would like to know whether the Directors had given any consideration to the question of this Company amalgamating or doing something of that kind. Would it be profitable to do so?

The CHAIRMAN said, in respect to the Brazilian group, the Brazilian Submarine and the Western and Brazilian Companies, which had done him the honour of making him Chairman, the West India and Panama Telegraph Co. had practically no connection in that direction at all. Their own connections were with the Cuba Company and the International Ocean Telegraph Co.

The resolution was then unanimously carried.

Digitized by Google

Mr. JOHN NEWTON proposed a vote of thanks to the Chairman, Directors and staff.

Mr. PANNELL seconded the vote, which was unanimously carried.

Mr. HOLMES said that he would like to offer just a few remarks before the meeting separated, as he regarded that meeting as the jubilee meeting of the Company, because it was just 25 years ago that the new Board of Directors came into office, and when they did so the state of affairs of the Company was very different from that at present existing. It was reported at that time that their cables were in a very bad condition, and that the life of the Company was only worth some seven or eight years' purchase. Well, he was pleased to think that that serious prognostication had not proved to be true, and he might tell them that their original cables were good cables, both mechanically and electrically, as was proved by the fact that the first cable laid between Santiago and Jamaica—a cable which had been down now for 28 years—was still working and was in good order. There were no doubt mistakes made at first in the laying, which was over rocks and sunken reefs and banks, but that had all been rectified by the removal of the cables to a better bottom; but they had an enemy at the bottom of the Caribbean Sea, where there were copper veins, or some other substances which affected the cables, and corrosion set in and faults were developed, which entailed a great deal of trouble and heavy expense. Well, he had lived another 25 years and the Company was still alive, and he regarded its prospects as better than ever, for instead of only having a single line of cables in bad order they would see if they looked at the map that they now had a network of duplicated cables in good condition right away from Santiago to Barbadoes and Demerara. He trusted they would do much better in the future than they had done in the past.

Mr. JOHN NEWTON corroborated the remarks of Mr. Holmes, and paid a tribute to the valuable services rendered by the Board during the past 25 years.

The CHAIRMAN briefly acknowledged the vote of thanks, and the proceedings terminated.

NEW COMPANIES, STATUTORY RETURNS, &c.

CANADIAN, BRITISH COLUMBIAN AND DAWSON CITY TELEGRAPH CO. (LIMITED).—This company was registered on Dec. 9, with a capital of £300,000, in £5 shares, to acquire the whole or part of the shares, debentures, debenture stock or other securities of the Dawson City and Victoria Telegraph Co. (Limited), incorporated in Canada by Act of Parliament, to construct, build, equip and operate a telegraph line from Victoria, B.C., to Dawson City, and to carry on the business of electricians, mechanical and electrical engineers, suppliers of electricity and manufacturers and workers of electrical apparatus, instruments, cables, wires, &c.

DOWSING RADIANT HEAT COMPANY (LIMITED).—This company was registered on Dec. 8, with a capital of £12,000, in £1 shares, to acquire, develop, work and deal with any patents, inventions or licences relating to heating and lighting by electricity for hygienic, therapeutic and general purposes. The first subscribers, each with one share, are:—W. Conolly, A. C. Newstead, Herbert J. Dowsing (electrical engineer), Mrs. C. J. Newstead, Mrs. E. E. Conolly, F. W. G. Conolly and Mrs. L. Dowsing. The first Directors are:—W. Conolly, A. C. Newstead and Herbert J. Dowsing.

ELECTRIC TESTED LAMP CO. (LIMITED).—This company was registered on Dec. 10, with a capital of £2,000, in £1 shares, to acquire the business carried on under the style of the Electric Lamp Contract Renewal Co., by Mr. R. T. Godman, and to supply, sell, repair and deal in electric lamps, machinery, instruments, apparatus, &c. The first subscribers are:—C. H. Cumberland, W. J. Williams, R. T. Godman, A. W. Gattie, A. W. Seaman (electrical engineer), W. Smith and H. St. Yorke.

ENGLISH DE LAVAL STEAM TURBINE CO. (LIMITED).—This company has been registered, with a capital of £100,000, in £10 shares, to manufacture and develop De Laval's patent steam turbines, to enter into agreements with Messrs. Greenwood and Batley and the Aktie Bolaget De Lavals Angturbin, and to carry on the business of steam, air, gas and water turbine manufacturers. The subscribers are: Arthur Greenwood, Henry Greenwood and John H. Wurtzburg, engineers (with 50 shares each); Daniel Norrman, engineer (50 shares); and Major-Gen. Micklem, S. T. Batley (engineer) and George Hagger (one share each). The first Directors are: Arthur Greenwood, Henry Greenwood, John H. Wurtzburg and Daniel Norrman.

S. M. VAN HINDEN ELECTRICAL CO. (LIMITED).—This company was registered on Dec. 2, with a capital of £1,000, in £1 shares, to enter into an agreement with Mr. S. M. Van Hinden, and to carry on at Liverpool or elsewhere the business of electricians, electrical and mechanical engineers, suppliers of electricity, manufacturers of electrical apparatus, &c. The first subscribers, each with one share, are: A. J. Vickary, S. M. Van Hinden, J. Beynon, Miss G. Vickary, I. Gorfunkle, W. Gorfunkle and Mrs. E. Vickary. The first Directors are: A. J. Vickary and S. M. Van Hinden.

P. C. MIDDLETON AND CO. (LIMITED).—This company was registered in Edinburgh on Dec. 9, with a capital of £50,000, in £1 shares, to acquire and carry on the business of electric light and power engineers, now carried on under the style of P. C. Middleton and Co. The first subscribers, with one share each, are:—P. C. Middleton (electrical engineer), N. Beves (engineer), W. Smith (engineer), J. Webster, J. Packman, J. Henderson and J. Morrison. The first directors are:—W. Jackson, P. C. Middleton (managing), N. Beves, J. Webster, J. Linney and H. Skipworth.

ALDERLEY AND WILMSLOW ELECTRIC SUPPLY (LIMITED).—The 1897 return was filed on Sept. 28. The capital is £30,000, in £1 shares (of which 10,000 are Preference). Seven shares have been taken up, on each of which 2s. 6d. has been called.

CHILIAN ELECTRIC TRAMWAY AND LIGHT COMPANY (LIMITED).—The statutory return, to Sept. 8, has been filed. Seven shares have been taken up out of a capital of £1,050,000, in £1 shares, and £7 has been received.

MONTE VIDEO TELEPHONE CO. (LIMITED).—The annual return to Nov. 14 has been filed. The capital is £160,000, divided into 87,000 Preference and 73,000 Ordinary shares of £1 each; 84,000 of the former and 71,000 of the latter have been taken up and issued as fully paid.

VENEZUELA TELEPHONE AND ELECTRICAL APPLIANCES CO. (LTD.).—The annual return to Nov. 18 has been filed. The capital is £85,000, divided into 70,000 shares of £1 each and 1,500 shares of £10 each. All the former and 860 of the latter have been taken up, and 56,506 £1 shares have been issued as fully paid. The full amount has been called on the others.

WIRELESS TELEGRAPH AND SIGNAL CO. (LIMITED).—The annual return to Oct. 21 has just been filed. The capital is £100,000, in £1 shares, of which 60,000 have been issued as fully paid, and £40,000 has been paid on the others. The capital has since been increased to £200,000 by the creation of 100,000 new shares of £1 each.

CITY NOTES.

MEMORANDA.—Bank rate 4 per cent. (since Oct. 13, 1898). Price of silver 27½d. per oz. (Dec. 15). Consols (2¾ per cent.) 110¼—110⅜ for money, 110½—110⅝ for account; 2½ per cent. 104½—104⅝ (Dec. 15). Stock Exchange Settling Days: Stocks and Shares Continuation Days, Dec. 28 and Jan. 11; Ticket Days, Dec. 29 and Jan. 12; Pay Days, Dec. 30 and Jan. 13; Mining Share Carry-over Days, Dec. 27 and Jan. 10.

BRISBANE TRAMWAYS CO. (LIMITED).—This week subscriptions have been invited for £167,900 Five per Cent. First Mortgage Debentures in this company, which was formed in 1895 to acquire the tramways in Brisbane, and convert them from horse to electric traction, and to extend the lines. The company has a virtual monopoly of the tramway traffic in the city and suburbs, the municipality having the right of purchase in October, 1917, at a price to be agreed. Mr. H. S. M. Woodrow, 52, Moorgate-street, London, E.C., is secretary.

CANADIAN, BRITISH COLUMBIAN AND DAWSON CITY TELEGRAPH CO. (LIMITED).—The subscription lists closed yesterday of an issue, at £95, of £225,000 Five per Cent. First Mortgage Debenture stock of this company, which has been formed with a share capital of £300,000, for the purpose of constructing and working telegraph lines authorised to be built by the Dawson City and Victoria Telegraph Co. (Limited), a company incorporated by Act of Parliament of the Dominion of Canada. The route traversed by the company's lines includes the mining centres of the Cariboo, Omenica and Cassiar districts, where a number of large mining and trading companies are operating. Further extensions of the lines are also to be made. This line is expected to be in operation by April next. The right is reserved to redeem, subject to six months' notice after the expiry of six years, the whole or part of these debentures at 110. The secretary and offices of the company are Mr. W. Young, 64, Victoria-street, London, E.C.

CAPE ELECTRIC TRAMWAYS (LIMITED).—The transfer registers of debentures will be closed from 18th to 31st inst. inclusive.

CENTRAL LONDON RAILWAY CO.—A further call of £2 per share on the Ordinary and Preferred partly paid shares of this company has been made, and is payable on Jan. 13.

CHELSEA ELECTRICITY SUPPLY CO. (LIMITED).—The books of this company will be closed from 14th to 31st inst., preparatory to the payment of the half-year's interest on the Debenture stock.

CITY OF LONDON ELECTRIC LIGHTING CO. (LIMITED).—The transfer books of the Debenture stock will be closed from 17th to 31st inst. inclusive, preparatory to payment of the interest due on Jan. 1.

DIRECT WEST INDIA CABLE CO. (LIMITED).—The Directors' report to June 30 last was presented to a meeting of shareholders on Wednesday, and resolutions approving the proposals of the Directors therein contained were adopted unanimously. The report was as follows:—The company's cables were successfully completed and opened to the public on Jan. 31 last. The Jamaica Government have passed a law granting the company a subsidy of £2,000 a year for five years, and the Turk's Island Government have agreed to give £120 per annum for a similar period. The revenue account shows a credit balance of £15,045. 8s. 7d., of which £10,490. 12s. 10d. has been applied to the discharge of all expenses incurred prior to the opening of the cable for traffic, including the discount at which the debentures were issued (£6,000), leaving available £4,554. 15s. 9d. It is proposed to pay a dividend for the half-year to June 30 at the rate of 5 per cent. per annum, absorbing £750, leaving £3,804. 15s. 9d. to be carried forward. A Stock Exchange quotation has been obtained for the debentures. Mr. Geo. G. Ward and Mr. Fred. Ward have been elected to seats at the board. Mr. T. G. H. Glynn and Mr. Joseph Rippon retire and offer themselves for re-election as Directors, as do Messrs. Gribbon, Holroyd and West as auditors.

DOULTON AND CO. (LIMITED).—The applications for the Five per Cent. Preference shares of this company amounted to nearly four millions and a quarter, and those for the Debenture stock to upwards of £2,500,000.

EDMUNDSONS' ELECTRICITY CORPORATION (LIMITED).—Applications are invited for £75,000 4½ per cent. First Mortgage Debenture Stock of this Corporation at par, £25,600 of which amount has been applied for by the directors and shareholders and is to be allotted in full. The prospectus (which is given on another page) announces that this stock will be secured by a trust deed creating a first charge upon debentures to which this

Digitized by Google

Company is entitled in various electricity supply companies, and by a floating charge upon the undertaking of the Corporation. This debenture stock is redeemable at the option of the Corporation after the 1st of January, 1913, on six months' notice at 105. The prospectus sets out the companies in which the Corporation is already interested, and gives some particulars of further contracts to which the present debenture issue is to be devoted. Application forms and further particulars can be obtained at the offices of the Corporation or from the solicitors or brokers. The list opens to-morrow (Saturday) and closes on or before Tuesday next, December 20th, at 4 p.m.

ELECTRIC CONSTRUCTION CO. (LIMITED).—A meeting of the Second Mortgage Debenture-holders will be held at Winchester House, E.C., on 21st inst., to consider a recommendation by the trustees (the Electric and General Investment Co.) to accept an offer to pay off, on Jan. 1, 1899, the outstanding balance of Electric Construction Co's. Six per Cent. Mortgage Debentures at 103 per cent.

ELECTRO CHEMICAL CO. (LIMITED).—This company are making an issue of £40,000, in Six per Cent. First Mortgage Debentures.

GREAT NORTHERN TELEGRAPH CO. (LIMITED).—The coupons falling due on Jan. 1 should be presented for payment at the office of Messrs. C. J. Hambro and Son, 70, Old Broad-street, E.C.

HALIFAX AND BERMUDAS CABLE CO. (LIMITED).—The report of the Directors of this company for the year to June 30 last, submitted to the shareholders on Wednesday, states that the delay in presenting the statements of account is due to the pressure arising from the accession of business during the Spanish-American war. Since last report the company contracted with the British Treasury to lay a cable to connect Bermuda with Jamaica, *via* Turk's Islands, and the Direct West India Cable Co. (Limited) was formed to undertake the work. The contract was signed on Aug. 2, 1897, and the cable was opened for traffic on Jan. 31, 1898. This extension greatly improves the position of the Halifax and Bermudas Company by giving it through traffic. The receipts in the past year were £10,154. 7s. 4d., compared with £3,742. 8s. 4d. in 1896-7. This increase is due to the opening of the Jamaica cable and to the interruption of other routes during the Spanish-American war. The net result is a profit of £6,655. 0s. 8d., compared with £951. 15s. 11d., an increase of £5,703. 4s. 9d. It is proposed to declare a dividend of 5 per cent., amounting to £2,500, leaving £4,155. 0s. 8d. to be carried forward. Offers for the sale of debentures to the trustees were invited in December and June last, and £4,989. 7s. 6d. was paid for £5,100 of debentures, which amount has been written off capital expenditure. A Stock Exchange quotation has been obtained for the debentures. Mr. Geo. G. Ward and Mr. Fred. Ward have been elected to seats at the board of the company. Mr. Charles R. Hosmer and Mr. Joseph Rippon retire, and offer themselves for re-election. At the meeting resolutions adopting the report, the dividend, the re-election of retiring Directors and auditors were carried unanimously.

NATIONAL TELEPHONE CO. (LIMITED).—The transfer books of the Three and a-Half per Cent. Debenture stock of this company will be closed from the 19th to 31st inst. inclusive, preparatory to the payment of the half-year's interim dividend due Jan. 1.

ROLLER-BEARINGS CO. (LIMITED).—The Directors' report for the year to Sept. 30 states that during this period much further experience has been gained in the practical application of this company's bearings, and several important improvements have been made, having for their object greater efficiency without adding materially to the cost. There has been a considerable development in the adoption of line shafting and heavy bearings, whilst their introduction for tramway work has increased to an extent which justifies the Directors in claiming that they are now in use in most of the principal cities and towns of the United Kingdom. The company's bearings are also in successful operation upon furnace cars, dynamos, broughams, motor-cars, heavy ventilating fans for collieries, and a variety of other machines. The number of bearings supplied in the year shows a considerable increase, the gross value of the trade done showing an increase of over 100 per cent. The Directors have made strenuous efforts to bring roller bearings prominently to the front. This has necessitated considerable expenditure of capital, which they believe will be remunerative, and will prove by future results to have been fully justified. Considerable progress has been made in the introduction of the bearings into France and Germany, and in the former country negotiations are still proceeding for the acquisition of the patent rights on remunerative terms to the company.

SHEFFIELD ELECTRIC LIGHT AND POWER CO. (LIMITED).—A dividend of 10 per cent. is announced. A meeting is called to wind up the company, consequent upon the purchase of its undertaking by the Sheffield Corporation.

STOCK EXCHANGE NOTICES.—The Stock Exchange committee has appointed Wednesday, Dec. 21, a special settling day in £100,000 Five per Cent. Perpetual Debenture stock of the *British Electric Traction Co. (Limited)* and 13,400 fully paid Ordinary shares of £5 each (Nos. 6,601 to 20,000) and 13,400 fully paid Five per Cent. Cumulative Preference shares of £5 each (Nos. 6,601 to 20,000) of the *Telegraph Manufacturing Co. (Limited)*, both securities to be quoted in the Official List. The committee has been requested to appoint a special settling-day in and to grant a quotation to 10,000 £5 Ordinary shares of the *Folkestone Electricity Supply Co. (Limited)*, and also to allow 15,000 Seven per Cent. £10 fully paid Cumulative Preference shares of the *British Aluminium Co. (Limited)*, and £100,000 Four per Cent. First Mortgage Debenture stock of the *London Electric Supply Corporation (Limited)*, to be quoted in the Official List.

WESTERN AND BRAZILIAN TELEGRAPH CO. (LIMITED).—This company's traffic receipts for the week ended Dec. 7 (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Co., Limited) were £2,973.

WESTERN UNION TELEPHONE CO.—This company has declared a quarterly dividend of 1¼ per cent.

NOTES.

THE letter addressed to the Colonial Secretary by Sir SANDFORD FLEMING in advocacy of his all-British, and State-owned submarine cables scheme is receiving a quite unusual amount of attention in the daily press, more by reason of its fitting in with the Imperial sentiment just now than because of its intrinsic merits. The novelty of the present suggestion is that the State—or more precisely the British, Canadian, Australian and New Zealand Governments—shall jointly lay down cables at their own expense from Western Canada *viâ* the Pacific to Australasia and round by way of India, Ceylon, the Cape, and thence to Bermuda and Halifax. The cost is estimated at from £5,000,000 to £6,000,000; and the one pertinent criticism by *The Times* in the course of a friendly leader is summed up in the question "Is the game worth the candle?" All the rest is a mere string of platitudes about coaling stations, concentration of fleets, duplication of lines of communication, and immunity from interruption, most of which is more or less erroneous, and the rest of no practical account.

SIR SANDFORD FLEMING'S arguments, if they are worth anything, go to show that the whole British cable system of the world should be owned by the State; but instead of suggesting their transfer from the Companies he advises the State to lay down cables of its own in competition—for that is what the scheme really amounts to. We cannot believe that it will ever be adopted in that shape, or on the scale recommended by its advocates. If there are strategical reasons for additional cables, these cables will be laid, no doubt, when and where necessity for them is proved; but it would surprise us very much did Mr. CHAMBERLAIN give his consent to the expenditure of so large a sum chiefly, if the truth be told, to reduce the by no means inordinate profits earned by the existing great cable companies, who have done all the hard work and accepted all its risks.

ACCORDING to the *Times* Ottawa correspondent, the Dominion has offered to contribute an equal share with the Imperial Government of the cost of a Pacific cable, the joint obligation not to exceed five-ninths of the whole cost, the Australasian colonies having undertaken to contribute the balance. This scheme, it should be observed, is not that recommended by Sir SANDFORD FLEMING, and stands probably as little chance of acceptance by the British Government.

PUBLIC interest in the telephone question is this month represented by the *Fortnightly Review* with an article from the pen of Mr. A. H. HASTIE, entitled "The Telephone Tangle and the Way to Untie it." With the tangle he is on sure ground, and appears to be in agreement with most writers on the subject, except perhaps in his personal leaning towards ceding the trunk wires to the National Company, and giving it all the powers needed for an effective monopoly. Failing this, his mode of untying the tangle is extremely simple. He values the shares and stock of the Company at about six and a-half millions; add 10 per cent. for compulsory purchase, and the whole thing will be in the hands of the State for, say, seven and a quarter millions—a capital sum to be borrowed at 2½ per cent. and the earnings from which will be doubled and trebled in no time.

MR. HASTIE is not in love with the Post Office, and he wants the telephone service to be placed under a separate and independent department whose duty it will be, among other things, to enable any gentleman shooting in the north of Scotland to have his London letters read out to him every morning *viâ* the trunk telephone wires. This is Mr. HASTIE'S ideal system; unfortunately it is not the ideal of sporting gentlemen, nor of a vast number of other persons who desire to be let alone in their privacy and their recreation. Telephone enthusiasts like the *Fortnightly Review's* contributor need to be reminded that the telephone was made for man, not man for the telephone.

WE publish in another column a full report of a case decided in the City of London Court on Monday. From the evidence it appears that a workman—who has at any rate since

Digitized by Google

the accident made up his mind that he is unskilled—while replacing a broken portion of a fuse-holder caused a short-circuit with a screw-driver and burnt his hand. The short-circuit was no doubt an accident directly attributable to the negligence of the workman, but probably the fact that the man was left in ignorance as to whether the fuse on which he was working carried current or not was one of the factors which influenced the judge in giving his verdict. It is evident that there was a distinct possibility of causing a short circuit unless care was taken in doing the job, and, whether the man was skilled or unskilled in the manipulation of screw-drivers, this should have been made quite clear to him.

An amusing example of the lay newspaper reporter's appreciation of technicalities is the *Standard's* account of the case, from which we quote below:—

> From the evidence for the plaintiff it seemed that . . . he was told . . . to do certain electrical work in connection with high-tension mains. While there an explosion of electricity occurred, and the plaintiff was very severely hurt on the left arm and hand. Had he been a little taller, the electricity would have struck his head, and he must have been killed instantaneously. As it was, he went to St. Bartholomew's Hospital, and was away from work for ten weeks. . . . The defence was that the plaintiff brought the accident about by not wearing india-rubber gloves, as provided by the rules. He himself caused the explosion by applying a screw-driver to an arc. . . .

Dr. Kallmann, the city electrician of Berlin, has always paid considerable attention to the problem of testing supply networks under working conditions, and a Paper by him, describing the systems of fault-signalling networks employed in the German capital, aroused considerable interest a few years ago. In another column we publish the substance of a further contribution of his to the subject of testing for earth leakages. The particular way he applies the double bridge is, we believe, new, although Mr. Quin has used a differential ammeter in a somewhat similar way for the purpose of detecting faults, and Dr. V. Krempelhuber has also recently proposed the employment of this instrument for observing the leakage from a three-wire network.

Of the various applications of Dr. Kallmann's system, the measurement of leakage from single feeders appears to be the most valuable. As we mentioned in a leading article a few weeks ago, the periodical testing of feeders is most important, and if Dr. Kallmann's method of continuous testing at the expense of a trifling C^2R loss proves as practical as it appears on paper it ought to be extensively employed. On the other hand, the system described for measuring stray currents from rail returns will, we think, hardly be found serviceable in practice, for if there are cars between the two pairs of test points (which the author says must be placed some kilometres apart) the current passing through the rails at the two ends of this section will not be the same even if there is no appreciable leakage from the rails to earth. The method for taking a continuous reading of the condition of house wiring is ingenious, but it must be borne in mind that the reading can only be considered an indication, and not a measurement, for it is not dependent merely on the insulation resistance of the installation under test. This fact is, however, alluded to by the author. The whole article merits careful perusal by the electricity supply engineer.

We give an account in another column of the inquest on the unfortunate workman who lost his life in Southampton. Work on "live" high-pressure mains and machinery is always attended with danger, whether the workman insulates himself or puts on rubber gloves, and such work should be avoided as much as possible. So many accidents, fatal and otherwise, have occurred in transformer pits and junction boxes that, except in cases of emergency, no work should be done in those places while the connections therein are charged. In Southampton no very serious inconvenience could have been caused by leaving the work over until the mains had been disconnected.

Cable Interruptions.—	Date of Interruption.
Para—Maranham	Nov. 15. 1898

David Salomons Scholarship.—The David Salomons scholarship for 1899 has been awarded by the Institution of Electrical Engineers to T. R. Renfree, student in the Siemens engineering laboratory of King's College.

Trunk Telephone Line.—A telephone line between Paris and Brest was opened on Saturday last, and it will probably be extended to Cherbourg in the near future. A line to Luxembourg, *vid* Longwy and Nancy, is projected.

The British Association and the Academie des Sciences.—It is now definitely announced that the next annual Congress of the Academie des Sciences will take place at Boulogne from Sept. 14 to Sept. 22, 1899, which is simultaneous with the meeting of the British Association at Dover.

Telegraphy in Egypt.—Instructions have been issued for a detachment of Royal Engineers to be made ready at once for service in Egypt and the Soudan. On arrival in Egypt the detachment will be told off for duty in connection with a scheme for developing the telegraph system in the Soudan.

Personal.—The order of knighthood has been conferred upon Mr. W. S. McDonald, the generous donor of many gifts to the McGill University of Montreal. Mr. Joseph Chamberlain has cabled to Mr. McDonald his thanks for the magnificent gifts to the university.——We hear that Prof. Röntgen has declined the offer of the appointment to the University of Leipsic.

New Electricity Supply Station.—The Salisbury Electric Light and Supply Co.'s works were formally opened by the Earl of Pembroke on Monday last. Messrs. Edmundson were the contractors for the complete works, which have been erected on an old mill site and are driven partly by a turbine and partly by steam. We reserve for a future issue a full description of the station.

Electric Traction in New York.—The Third Avenue Railway Co. of New York, having decided to abandon its cable equipment for electric power, has awarded the contract for the steam and electrical equipment of its power house, which will contain machinery capable of developing 64,000 H.P., and for its street railway lines, to the Westinghouse Electric and Manufacturing Co. of Pittsburgh. The undertaking involves the expenditure of rather more than a million sterling.

Royal Institution.—Among the lectures announced before Easter is a course of seven, by Lord Rayleigh, on the mechanical properties of bodies. The Friday evening meetings will begin on January 20th, when a Discourse will be delivered by Prof. Dewar on "Liquid Hydrogen"; succeeding Discourses will probably be given by, among others, Prof. H. S. Hele-Shaw, Prof. H. L. Callendar, and Lord Rayleigh. The year 1899 is the Centenary Year of the Royal Institution, and arrangements are being made with a view to its celebration in a fitting matter. Details will be announced at a later period.

Wireless Telegraphy.—During the present week the Wireless Telegraph Co. have been occupied in equipping a lighthouse and a lightship on the south coast with instruments to enable wireless telegraphic communication to be established

Digitized by Google

between the ship and the shore. The Trinity House authorities have placed at the Company's disposal a room in the South Foreland Lighthouse, and have allowed a choice of one of the three lightships of this part of the English coast, between which two points the experiments are to be made. It is expected that these stations will shortly be in full working order on the Marconi system.

Cost of Electric Cooking.—In a Paper on "The Practical Applications of Electrical Power," read by Mr. H. R. J. Burstall before the Royal Institution of British Architects on Monday night, the following table, compiled by Mr. C. O. Grimshaw, of the Westminster Company, was given:—

Cost of Running Cooking Apparatus at 4d. per Unit.

Description.	Capacity.	Cost per hour.	Cost for one operation from all cold.
Kettle	1½ pints	... 1·28d. ...	0·45d.
Griller...	2 chops	... 2·24d. ...	0·53d.
Saucepan.....	2 quarts.	... 1·6d. ...	0·8d.
Fish kettle	16 quarts	... 4·56d. ...	—
Domestic iron...	Scorching paper	... 0·8d. ...	Cost to heat up, 0·13d.

Scientific Nomenclature.—During the course of an address to the members of the Yorkshire Naturalist Union at Scarborough, on Saturday, Prof. Michael Foster, the retiring president of the union, said that a great drawback to the spread of science was the fact that every day the English language was being enlarged by the introduction of new words to which science, in its different branches, contributed the largest proportion. The meaning of those new words became known only to those who had to make frequent use of them, and new terms were often forced on those utterly ignorant of their meaning. To carry on the work of science it was necessary, as far as possible, to use words which were in touch with the modern development of science.

"La Poste Electrique Internationale."—A company bearing this name is being promoted in Brussels, having a capital of £320,000, with the object of erecting charging stations for motor-cars at distances of 10 or 12 miles apart on the main roads in France and Belgium. The stations are to be equipped with machinery for charging accumulators and also to be provided with the necessaries for charging oil-motors and repairing all classes of motor-cars and cycles. It is also intended to have a restaurant or bar, and, in addition, to provide for medical attendance, so that the travellers can be recharged and repaired as well. The roads on which the company propose to start operations are on the main route from Brussels to Paris by way of the Meuse valley.

Obituary.—With much regret we record the death, after a short illness, of Mr. James Brown, superintendent of the Direct United States Cable Co.'s station at New York, at the age of 47. Mr. Brown was originally in the postal telegraph. service in Aberdeen, and joined the Direct Company in 1874, being sent to the Rye Beach, New Hampshire, Station. When Mr. G. G. Ward was appointed representative of the company in New York, Mr. Brown was transferred to that station as clerk-in-charge, and occupied that position until 1884, when he succeeded to the superintendency on the resignation of Mr. Ward. Mr. Brown filled his post to the satisfaction of the company as well as with credit to himself, and the company loses in him a hard-working, conscientious and painstaking official. His interment took place on the 20th inst. at Kensico Cemetery, near New York, several prominent officials of the Western Union and other telegraph companies acting as pall-bearers. Mr. Brown leaves a wife and family and a large circle of friends to deplore his early death.

An Addition to the French Telephone System.—An article has been going the round of the New York papers, to the effect that important improvements are to be introduced in the French telephone service, which will extend it considerably. We believe that the only alteration contemplated is the establishment of a system by means of which any subscriber or non-subscriber will be enabled to make an appointment with any other individual (who need not either be a telephone subscriber), to be in attendance at the latter's instrument or at a call office at a stated time. These appointment messages will be transmitted for 2½d. within a distance of 15 miles, and for greater distances a higher charge will be made, but not exceeding 5d. The message making the appointment will be delivered at the recipient's house just as a telegram, and will be in the form: Mr....., of ....., requests you to be at call office no....., at ..... o'clock. Such a system would be of great value for trunk conversations in this country—in fact, this was suggested by Mr. Campbell Swinton in the discussion on Mr. Gavey's telephone Paper at the Institution in 1896.

A Severe Snowstorm visited a wide area of the eastern part of the United States on November 26 and 27. The fall of snow was very heavy, and the accompanying wind caused the snow to drift badly in the streets of the cities and towns, and prostrated telephone and telegraph wires in the suburban districts. The street-railway service of New York was badly impaired in consequence of the storm. This was the first real test of the ability of the open-slot system to meet the severe conditions of wintry weather. This system, together with all others, excepting the elevated railroads, was paralysed for 24 hours or more, being entirely shut down from Saturday evening until Sunday evening. The stalled cars were bunched in groups around the city, impeding all efforts to clear the tracks by sweepers or ploughs. The fault is not entirely that of the electrical conduit, however, as the Metropolitan Street Railway Co., owing to the recent expansion of its system, has not provided itself with sufficient electrical ploughs and sweepers. The cleaning of the tracks had to be done mainly by horse power, and the heavy double-truck electric cars stalled along the line greatly impeded the work. The cable roads fared better than any other of the surface lines, especially as the cable sweepers do not lose their tractive effort, no matter how heavy the ice or snow, but pull right through with a force that no drift can resist. Such storms, however, very rarely visit New York, and it is not likely that this last experience will be repeated. With a sufficient battery of sweepers to keep the track free of snow as it falls, such a general tie-up will probably never occur again. Throughout the eastern section of the country overhead trolley lines were blocked to such an extent that traffic was greatly impeded for the time being.

Accidents and Interruptions.—*Bristol.*—A curious accident occurred at Kingswood, near Bristol, on Monday. The accident was caused by a runaway trolley—not an electric trolley-car, but a horse-driven railway trolley. This came into collision with a wooden lamp-post, which it broke. The lighting here is on the Parfitt overhead series system, from the Western Counties Electric Light and Power Syndicate's station, and the overhead lighting wires, falling across the wires of the electric tramway, caused a startling display of fireworks and a few slight shocks. The tram system was, however, not damaged in any way, and the service was resumed as soon as the wire could be disentangled.

Norwich.—Another serious interruption occurred in the supply at Norwich on Friday last week. A short-circuit occurred between the negative and neutral mains on one of the principal feeders, and in attempting to burn it out other short circuits were set up elsewhere and affected all three mains. In disconnecting to set matters right, the neutral main was unfortunately cut in one part, with the result that one side of the three-wire system in part of the town acquired too high a pressure, and some lamps and fittings burst, as at Wickham a short time ago. The Norwich company has now issued the following circular letter to its consumers:—

Dear Sir: I am instructed to state that in consequence of the extraordinary demand for electric light, the Company has experienced great difficulty in sustaining a full supply, the regrettable failure of last Friday being due to this cause and to the anxiety of the directors to meet the requirements of all their consumers.

As the demand during Christmas week (commencing Dec. 19) will be greater than ever, the Board appeals to its customers asking them not to turn on more lights than are actually required during the maximum load viz., between the hours of 4 and 6 o'clock.

The directors need hardly assure the public that they are doing everything possible to provide against the recurrence of such an accident in the future, whilst they greatly regret the inconvenience caused by last night's failure.

Manchester.—Owing to the failure of a rubber cable last Sunday, the electric light in some of the churches went out. The gravity of the mishap has been greatly exaggerated in the local press.

CONTEMPORARY ELECTRICAL SCIENCE.

[Compiled by E. E. Fournier d'Albe.]

Loud Transmission of Sound.—M. Dussaud has studied the best means of intensifying the sound transmitted by a microphone to a telephone receiver. He produced a steady sound by means of an electrically-driven tuning fork placed in front of an extremely sensitive microphone. At the receiver end the circuit divided into four branches, each actuating a separate telephone membrane. M. Dussaud tried various combinations of the four receivers, and found that the more numerous they were the louder was the sound. It was also found advantageous to collect the vibrations from both sides of the membranes. He employed a set of collecting tubes all leading into a resonator of the shape and size of a human mouth. He thus was enabled to reproduce the sound of wind instruments and the human voice in a large hall accommodating 1,000 persons and with such loudness that they could be heard in every part of the hall. On the State Telephone system of Geneva communication was established between two subscribers in such a manner that ordinary speech could be heard in every part of the room. As only two Leclanchés were used, the increased efficiency was solely due to the new arrangement for transmission.

[Dussaud, *Comptes Rendus*, Dec. 5, 1898.]

Resistance between Steel Spheres.—If the effect of the pressure between two conductors in contact upon their electric resistance could be accurately determined, some light would probably be cast upon the nature of metallic conduction. F. Auerbach reports upon some valuable experiments made with this object by A. Meyer, of Stockholm, who pressed two geometrically true and perfectly polished steel spheres together and determined their resistance when the pressure was varied. The effect of the pressure is, of course, to flatten both spheres to an extent depending upon their elasticity. The flattened contact surfaces offer a freer passage to the current than is offered by a mere point of contact. Now it is conceivable that the conductivity of the contact surface is simply proportional to its area. On the other hand, it might also depend upon the pressure. Meyer's spheres showed that both these elements enter into action. They varied from 4cm. to 10cm. in diameter, and were pressed together with forces of 85gr. to 1,000gr. To ensure comparable results they had to be exposed to the vibration of a tuning fork before every measurement. The results show that the conductivity varies directly as the area of contact, and as the integral of the pressure. This means that the relation is not a geometrical one, but also an electrical one. Any theory of metallic conduction must therefore be able to account for the proportionality between conductivity and pressure before it is accepted.

[Auerbach, *Wied. Ann.*, No. 12, 1898.]

Electric Dispersion.—E. Marx has extended Drude's work with Blondlot exciter and short-wire waves by loosening the coupling between the primary and the secondary system. This has the effect of allowing the proper oscillations of the primary to develop themselves independently of the influence of the secondary, and the author thus shortened Drude's smallest waves of 12cm. to 4cm. The smallness of the waves allows of measurements of electric refractive indices of solutions by Drude's method even when the conductivity is as high as 4×10^{-6}. Such measurements were carried out for wide ranges of the electric spectrum with regard to water, benzol, and ethyl alcohol. The study of benzol yielded the interesting result that substance has, in the whole region from the ultra-violet to waves of infinite length, only one absorption band of any size. This fact makes it possible to estimate the inductance of the benzol molecule. But, on the other hand, benzol does not obey the Ketteler-Helmholtz dispersion formula, whereas ethyl alcohol does. In water the maxima and minima of the refractive index follow each other in double octaves, with decreasing intensity. Hence there are many absorption bands in the infra-red. This, according to the electromagnetic theory of light, implies an increasing divergence between the dielectric constant and the optical refractive index, and thus accounts for the unusually high value of the refractive index of water for infinitely long waves.

[Marx, *Wied. Ann.*, Nos. 11 and 12, 1898.]

Magnetic Susceptibilities.—J. Koenigsberger has accumulated a large mass of material from which to draw a number of more or less well-founded conclusions. The field of magnetic susceptibilities is almost virgin ground for the ambitious pioneer, as the quantities involved are, as a rule, extremely small, and an error of 200 per cent. is nothing out of the way. There are, however, a few solid facts brought out by the author which embody a good deal of careful work. The susceptibility of water, determined by several methods, was found consistently to be $-0{\cdot}8 \times 10^{-6}$ at 20deg. as against air. H. du Bois's theorem, according to which the susceptibility of ferric chloride solutions and other solutions is constant in various fields, so long as they contain no free iron, was confirmed. The susceptibility of aqueous solutions of paramagnetic and diamagnetic salts may be determined from that of the solvent, from the concentration, and from the susceptibility of the solid substance itself. The susceptibility of diamagnetic solids is independent of the strength of field. The author has traced some probable connection between atomic volume and atomic magnetism. He finds that bodies which have the smallest atomic volume are also most strongly paramagnetic. This analogy is worth following up, as it may help us to a clearer insight into the nature of magnetisation.

[Koenigsberger, *Wied. Ann.*, No. 12, 1898.]

Becquerel Rays.—What is the origin of uranium rays? This question is one of the most puzzling problems of modern physics. Uranium and thorium and some of their compounds have the property of sending out rays, called Becquerel rays after their discoverer, which exert photographic effects through opaque substances and impart a temporary conductivity to gases which they traverse. These properties are the same as those possessed by Röntgen rays, but whereas the origin of the energy of the latter is well known, and their nature is in a fair way of being explained, the energy displayed by uranium appears to be an open defiance of the law of the conservation of energy. Three more or less daring hypotheses have been put forward to account for it. Madame Curie supposes that all space is pervaded by rays somewhat of the nature of Röntgen Rays, but more subtle, which are only absorbed by bodies of specially high atomic weights, like uranium and thorium. Crookes surmises that these substances have what Maxwell would have called the demoniac power of absorbing some of the kinetic energy of gaseous molecules impinging upon them and emitting it in the form of Becquerel rays. A third hypothesis supposes that uranium and similar substances combine with some unknown constituent of the atmosphere by an exothermic reaction. J. Elster and H. Geitel have endeavoured to discriminate between those hypotheses, using the highly efficient uranium pitch ore of Joachimsthal for the purpose. They first tried it in a vacuum, but without noting any difference. This is a serious blow to the chemical hypothesis and to Crookes's assumption. Then they tried to shield uranium from Madame Curie's rays by taking it to the bottom of a mine, 850m. below the surface. But that expedient failed to affect the uranium. So unless those hypothetical rays are capable of penetrating 3,000ft. of rock with ease, the Becquerel rays are still completely unaccounted for.

[Elster and Geitel, *Wied. Ann.*, No. 12, 1898.]

An Electrical Exhibition Next Year.—It is evident that the Electrical Exhibition which was held at Madison Square Garden this year was successful, as a commercial enterprise, inasmuch as the managers have decided to hold another affair of this character next year. The Exhibition will be held in this city, but just where and at what time it has not yet been decided.

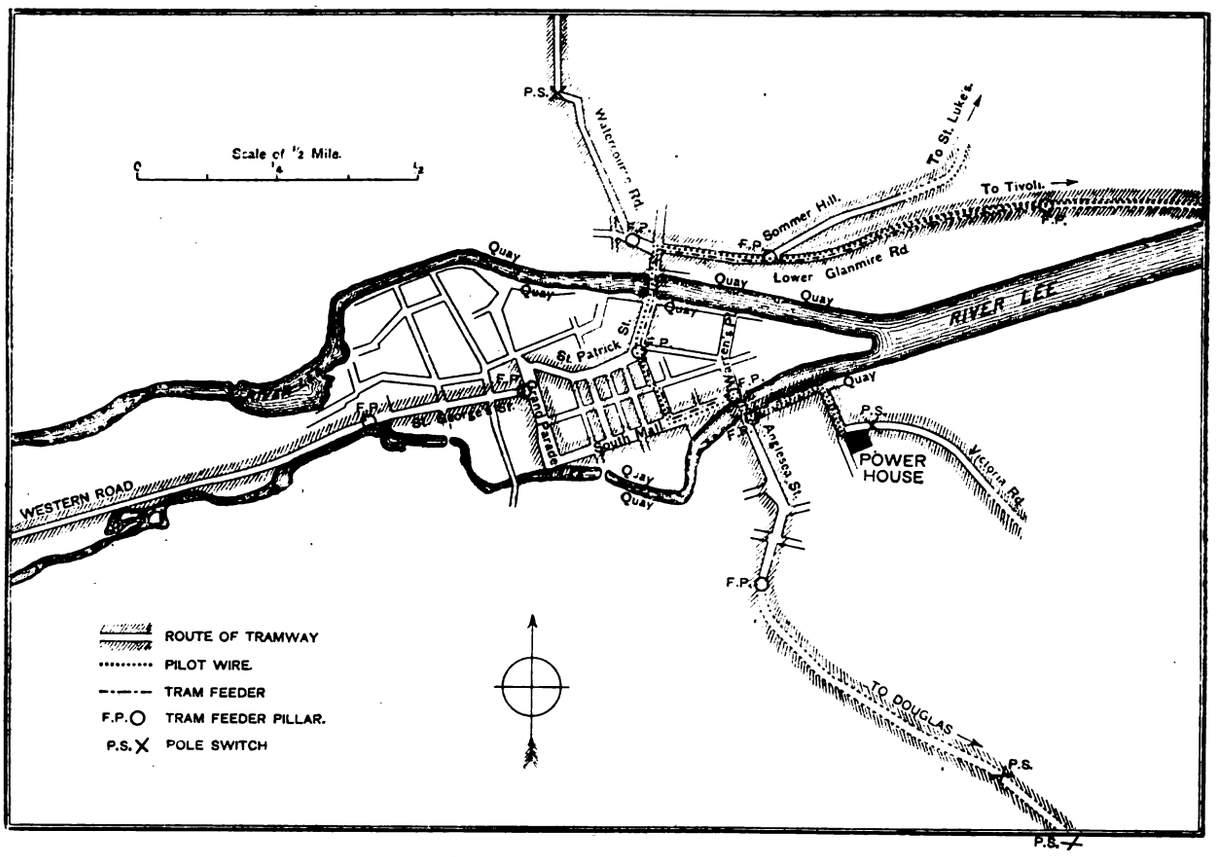
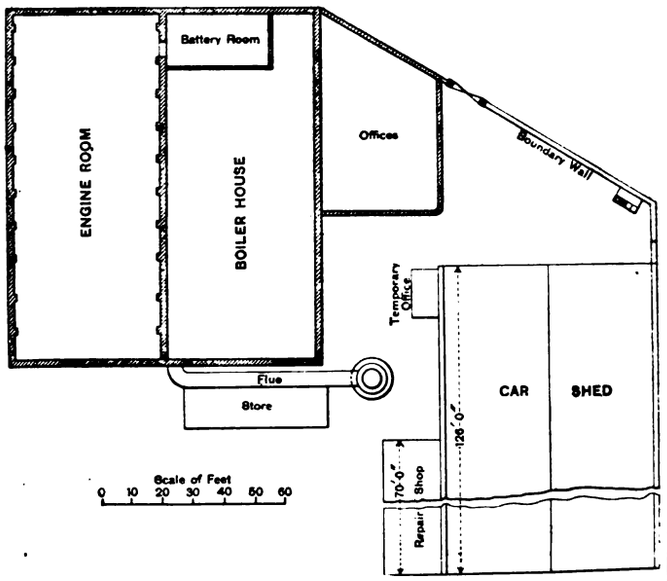
CORK COMBINED ELECTRIC LIGHTING AND TRACTION SYSTEM.

The current for the electric lighting of Cork and for the propulsion of the tramways in that town is generated from one station. The extent of the lighting district and the route of the tramways are shown in the two maps below. It will be seen that the power-house is situated at a corner of both the lighting and tramway networks, but that it is situated at no very great distance (220ft.) from the River Lee. It is built on piles, and is a brick-built building faced with Ruabon bricks.



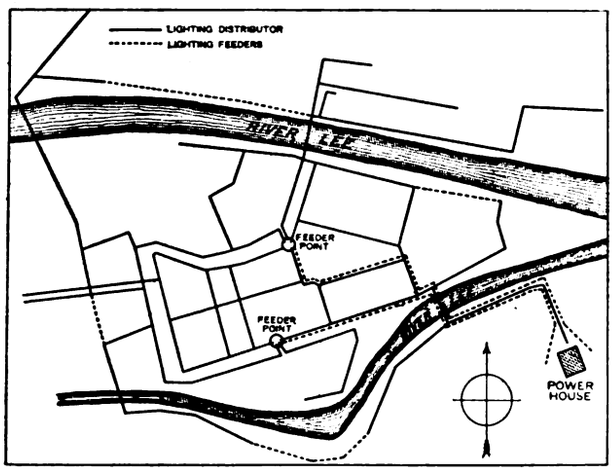
Map Showing Route of Tramway, Feeders, &c.

We give a view of the boiler-room. The three boilers are of the Babcock-Wilcox type, each with 2,531 sq. ft. heating surface and capable of evaporating 8,000lb. of water per hour. Their normal working pressure is 150lb. per square inch. The chimney stack is of steel, erected on concrete foundations, and self-supporting. It is 180ft. high, 7ft. internal diameter, and lined with firebrick. The thickness of the plates at the base is $\frac{7}{16}$in., and the size of each plate is 4ft. by 6ft., there being three plates to the ring.



Plan of Generating Station.

A feed heater of simple construction is used, made by the Wheeler Condensing and Engineering Co., the feed water being heated by the exhaust from the feed pumps and condenser pumps. The feed pumps are of the Blake and Knowles type, arranged compound. The diameter of the high-pressure cylinder is 6in., low pressure 9in., water cylinder 4in., and the stroke is 8in. The steam cylinders of these pumps are

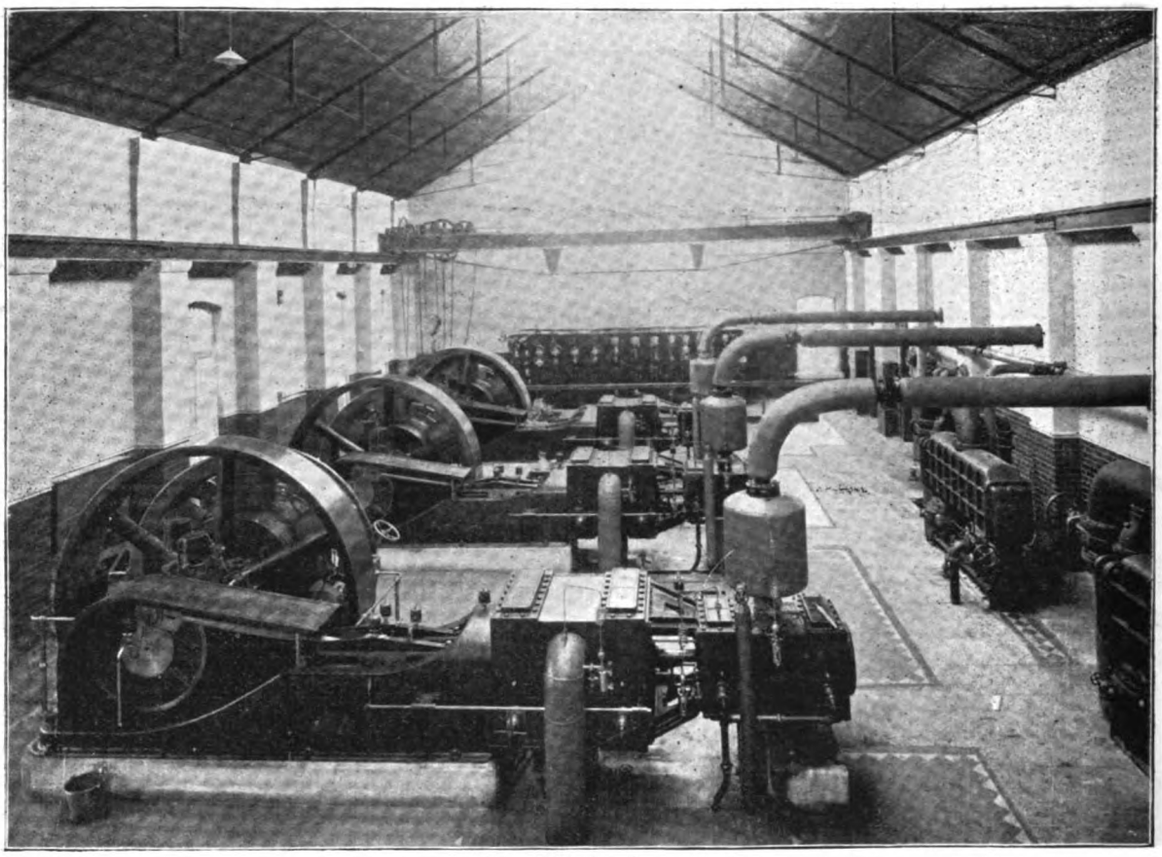


Plan of Lighting Network at Cork.

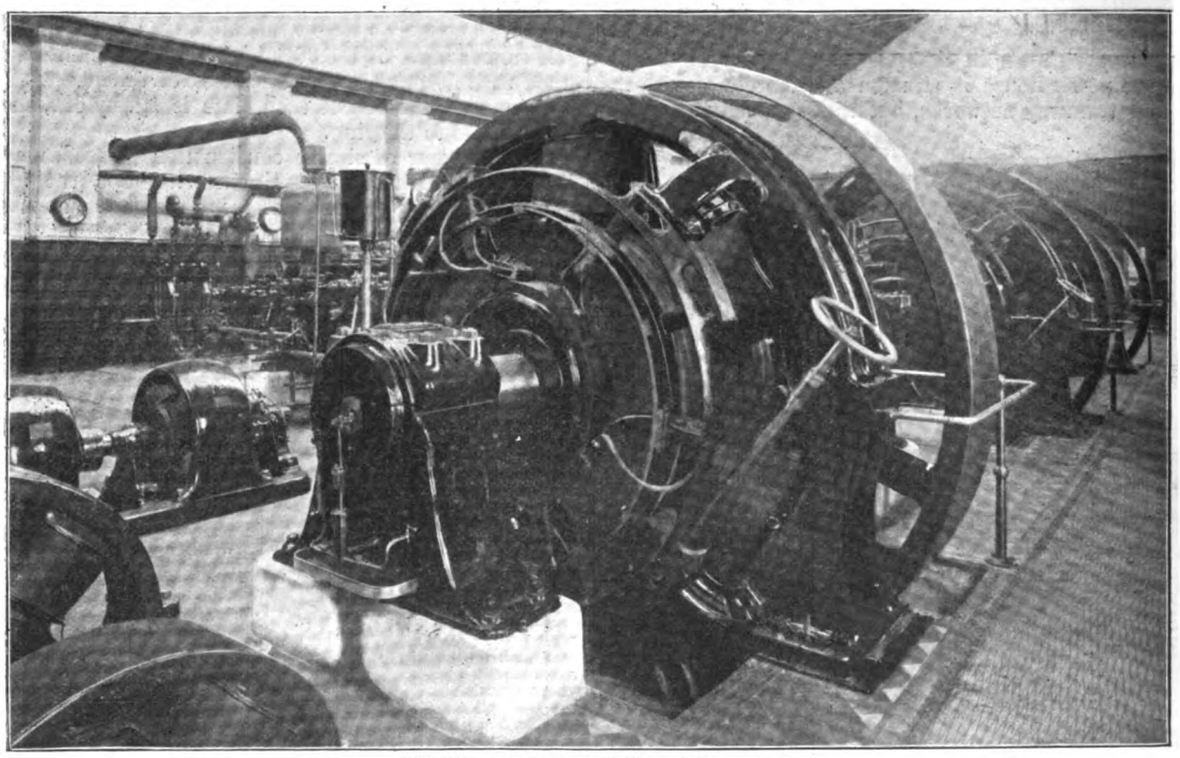
Digitized by Google

fitted with an outside valve gear, so arranged that it can be adjusted to all conditions of speed. The arrangement of the steam connections is such that, in case of any repair being required, either pump can work independently of the other.

tank, the oil, which will be floating on the surface, can be run off. Edmiston filters are used to filter the feed water before it enters the boiler. The two filters are capable of filtering 16,000lb. of water per hour. They are arranged on the twin



View of Engine Room.



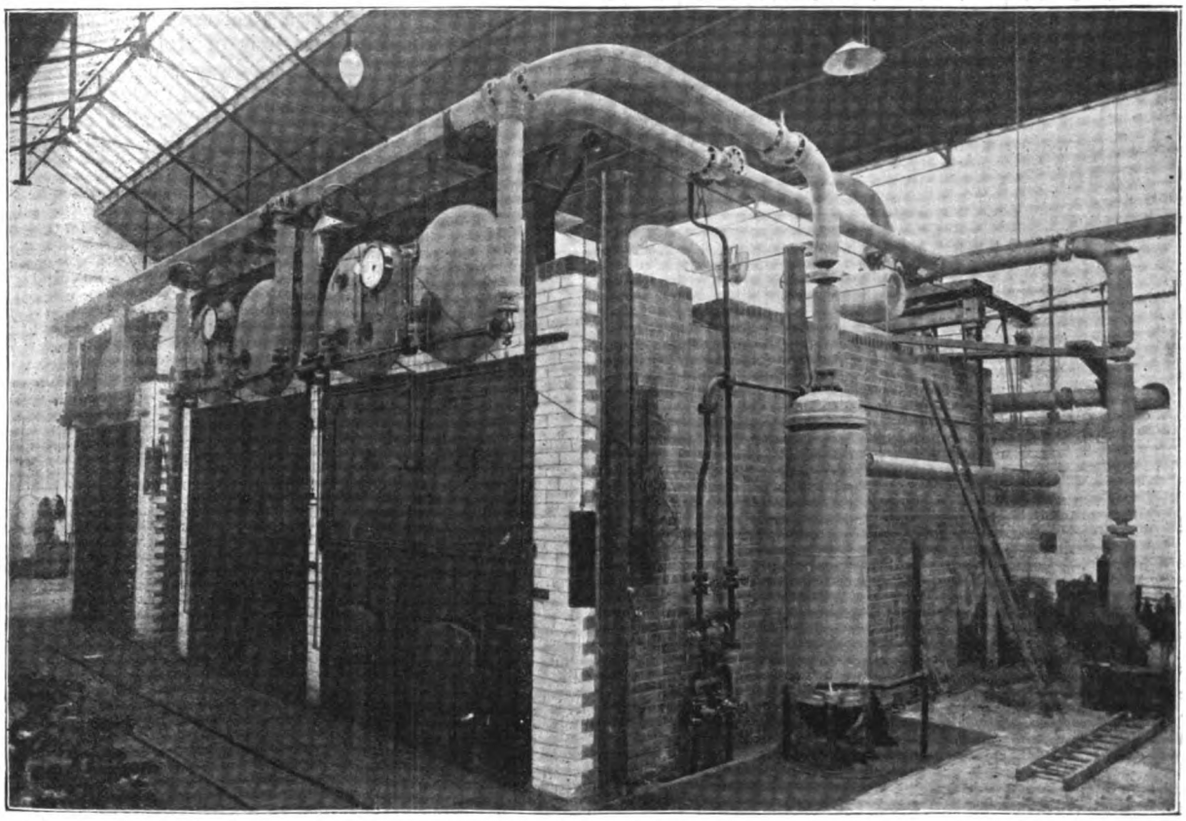
200-Kilowatt Compound-Wound Generator.

The hot well is situated in the boiler house; it is fitted with baffle plates, and the divisions of it can be filled with coke and straw if desired, for the purpose of intercepting any oil that may be discharged into it. By opening the valve and filling the system, fitted with valves to enable the filters to be used on either range of feed pipes.

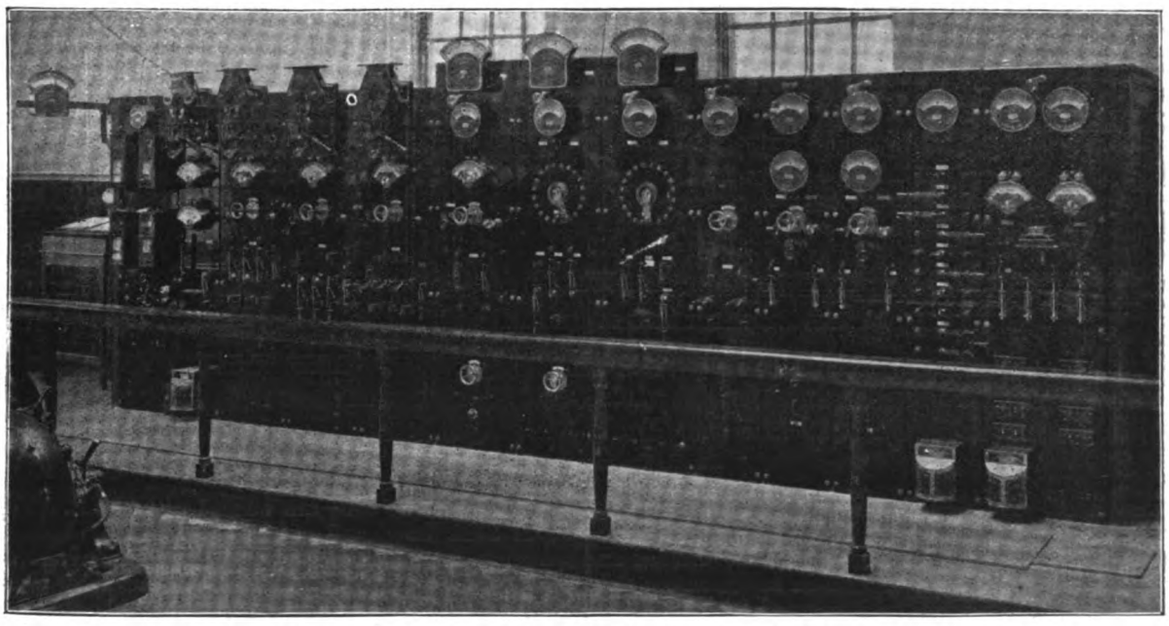
The steam pipes are of steel, fitted with heavy steel screwed flanges, and any engine can be fitted directly from the boiler

Digitized by Google

immediately behind it (*see* plan of station). Valves are, of course, inserted to enable any faulty section in the piping to be cut out. An automatic atmospheric valve is also fitted, which will slow the engines to exhaust directly into the atmosphere in the event of there being any pressure due to the failure of the condensing plant. The pipe on the atmosphere side of this valve is of thin steel, rivetted in spirals.



View of Boiler Room.



Combined Traction and Lighting Switchboard.

The engine room, a view of which is given on another page, contains three Macintosh and Seymour side-crank, tandem, compound, condensing engines. These run at 135 revolutions per minute, and are fitted with expansion governors and separate exhaust valves on both high and low-pressure cylinders. The high-pressure cylinder is steam-jacketed and exhausts into a reservoir in the interior of which are three copper coils which can be heated with live steam. Condensers of the Wheeler Admiralty type are used, the engines being arranged in the centre, the air pump at one end and the circulating water pump at the other end. Each of these condensers is capable of dealing with 12,000lb. of steam per hour. The condensing water is taken directly from the river through 12in. cast-iron pipes, there being an auxiliary supply from the waterworks, which can be laid on to start the pumps if the suction pipe is empty owing to the retaining valve not being perfectly watertight.

Each of the engines is coupled directly to a 6-polar 200 kilowatt compound-wound generator, giving 500 volts at 135 revolutions per minute. These dynamos are of the usual British Thomson-Houston railway generator type (*see* illustration) and do not merit any special description. A battery is provided which can be charged either from the traction or

Digitized by Google

lighting 'bus-bars, a booster being employed to supply the necessary extra voltage. The booster can also be driven from either pair of 'bus bars.

The 256 Tudor cells in the battery room are mounted in three tiers. Each cell contains six positive and seven negative plates. The capacity of the battery is 770 ampere hours for a normal seven hour discharge, and its maximum rate is 210 amperes. Pitch pine, painted with acid-proof paint, is used for the battery stands, which are insulated on large oil insulators.

The switchboard, of which we give both a photographic and diagrammatic view, is situated at the end of the engine room. It contains three generator panels, fitted with automatic circuit breakers with magnetic blow-outs and change-over switches, so that the generators can be connected either directly to the lighting or traction 'bus-bars. Besides the generator panels, there are two feeder panels, two balancer panels and one panel fitted with the testing instruments required by the Board of Trade. The former pair of panels is fitted with the necessary regulating switches and magnetic blow-outs, arranged so that the battery can either be charged or discharged from either the lighting or traction 'bus-bars, as already mentioned. By a suitable arrangement on the balancer panels, this machine can be driven from the traction bars, if so desired, in the day-time; or it can be used as an ordinary balancer with the two motors in series across the outers of the lighting 'bus-bars, the junction being connected to the neutral. In the latter case, the set is run up to give its correct voltage by means of a motor placed in the centre, which is then disconnected as soon as the balancer sets are reconnected to the network. There is a large repair shop, containing the machine-tools and forge likely to be required for the maintenance of the machinery and cars.

Sixteen double-deck cars built by the Brush Electrical Engineering Co., and capable of seating 44 persons, have been provided. They are mounted on single Peckham trucks, and equipped with two "G.E. 60" motors and series-parallel controllers. Except in respect of the motors, which have had to be specially designed, on account of the very narrow gauge (2ft. 11½in.), the car equipment follows the usual standard practice of the British Thomson-Houston Co. The line is double track through all the principal streets, with some branches, as shown in the map. The longest part is to Douglas, a village about two miles south of Cork. As seen in the map, the line crosses the river twice—first, over the Parnell Bridge, which is a steel swing bridge, and, secondly, over Patrick's Bridge, which is of stone. The rails are laid on a bed of concrete, the roadway being paved between the rails and for 18in. outside the rails. Our illustration shows a part of the track where double bracket centre poles are used. In some places double bracket side poles are used instead, in which case the distance between the two tracks is reduced by 2ft. Outside the city boundaries the rails are laid on creosoted sleepers, 6ft. by 4½in. by 9in. Ordinary girder rails are used, weighing 83lb. per yard, with steel fish-plates 26in. long, weighing 56lb. per pair. The tie-bars are of wrought iron, 2in. by ⅜in. They are double screwed at the ends, and weigh 10½lb. each. The rails are fixed to the sleepers by 80 dog-spikes and 14 fang bolts, and chips to each rail length. The rails are bonded with 000 B. & S. Chicago bonds 35in. long, and at the points long bonds are used spanning the steel castings. At each crossing there are four 000 B. & S. 35in. bonds, and the rails are also cross-bonded every 240ft. Where the tracks are double they are cross-bonded at intervals of 240ft., these bonds being placed halfway between the rail cross-bonds. To prevent any interruption in the return circuit when the Parnell Bridge is swung open, four ½in. cables connect the rails on either side of the water, these being fastened to the rails by bonds.

Span wires are only used in a few places; in the principal streets centre poles with double bracket arms are employed, and on the remainder of the line side poles, as illustrated. The trolley wire is of hard-drawn copper, and is double throughout. Where it crosses the swing part of the Parnell

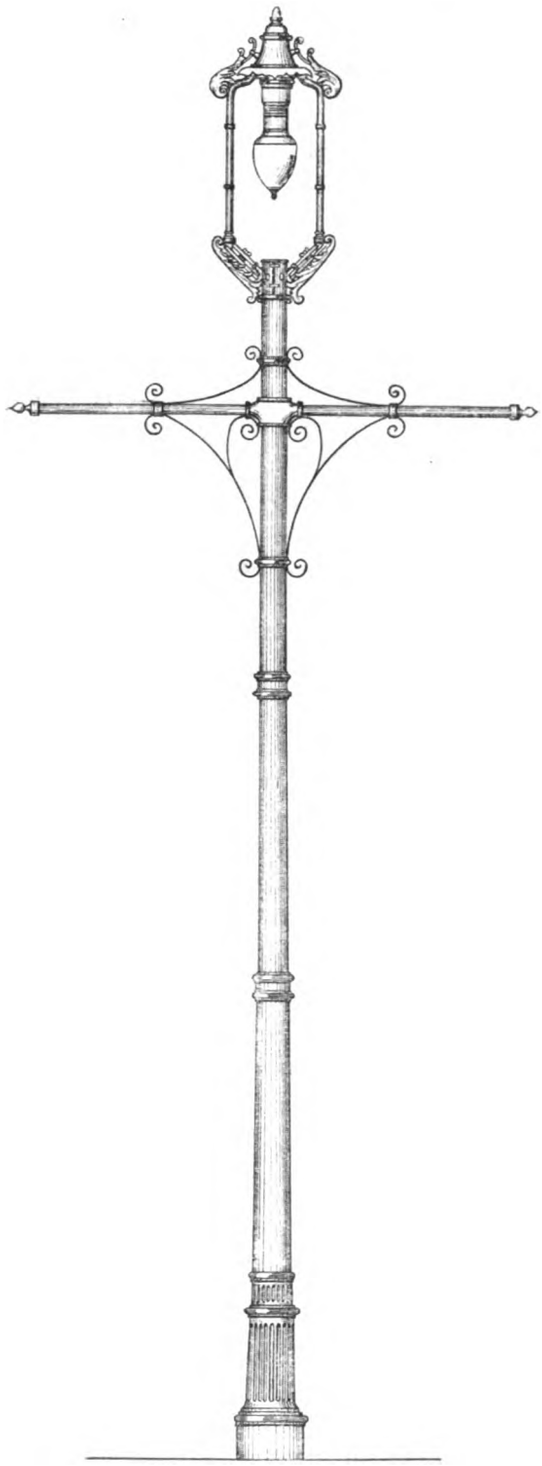
Bridge, it is supported on special poles and brackets fastened to the movable part of the bridge, with heavy spring clips, which allow the bridge to be moved in either direction.

The lighting network is on the three-wire system, with 460 volts between the outers. Over 20 miles of cable have been laid for lighting and traction, the cable in the majority of cases consisting of Callender's lead-covered steel-tapered armoured cable laid directly in the ground. There are at present



Double Bracket Trolley and Arc Lamp Post at Cork.

only two feeding points on the lighting system distant from the station by about half a mile. The feeders cross the River Lee, and here they are laid in a trench excavated in the bed of the river. Four additional feeder cables have been laid as spare, to allow for future extensions. The feeders are of 0·7 sq. in. section, and the distributors of various sizes, the largest having a sectional area of 0·15 sq. in. In the centre of the city three-core distributors are used, and in the outlying districts three single distributing cables which are protected by a covering of bricks in addition to their armouring. Nineteen Callender's disconnecting boxes are fitted at various junctions of the network.

Street lighting has not been permanently started yet, but will be shortly. In the principal streets an arc lamp is fixed on every alternate centre pole, as shown in the illustration. Enclosed arcs are used, connected five in series, and so arranged that alternate lamps are on different circuits. The switches and resistances are contained in the bases of the poles, and, as usual, a compensating resistance can be switched in circuit with any lamp.

The supply of current on the lighting network was started about the beginning of September, and since then about 130 consumers have been connected to the mains. In all, 217 intending consumers have now applied for connections, these representing an equivalent of 14,447 8 c.p. lamps, including 113 H.P. in motors. The price charged for the light is 5d. per unit for the first two hours on the maximum demand system, and 1d. afterwards. For power the present tariff is 4½d. for the first two hours, and also 1d. afterwards.

Side-Pole and Car.

The British Thomson-Houston Company were the contractors to the Cork Electric Tramways and Lighting Co. for the work as a whole and themselves supplied the complete electrical equipment. The following were the chief sub-contractors to the British Thomson-Houston Company :—

Permanent way, power house buildings, &c.	Mr. W. M. Murphy, Dublin.
Engines	Messrs. R. W. Blackwell and Co., London.
Boilers	Messrs. Babcock & Wilcox (Ltd.), London.
Auxiliary apparatus, pumps, condensers, &c.	The Wheeler Condenser and Engineering Co. and the Blake and Knowles Steam Pump Works (Limited), London.
Battery	The Tudor Accumulator Co. (Ltd.), London.
Traveller	Messrs. Jessop and Appleby, Leicester.
Cars	The Brush Electrical Engineering Co. (Limited), Loughborough.
Peckham trucks	Messrs. R. W. Blackwell and Co., London.
Overhead line construction	Messrs. R. W. Blackwell and Co., London.
Lighting, network and cables.	Callender's Cable and Construction Co. (Limited), London.
Arc lamps and hoods	The General Electric Co. (Ltd.), London.

Alderman Fitzgerald, of Cork, was sub-contractor to Mr. W. M. Murphy for the buildings in connection with the power house.

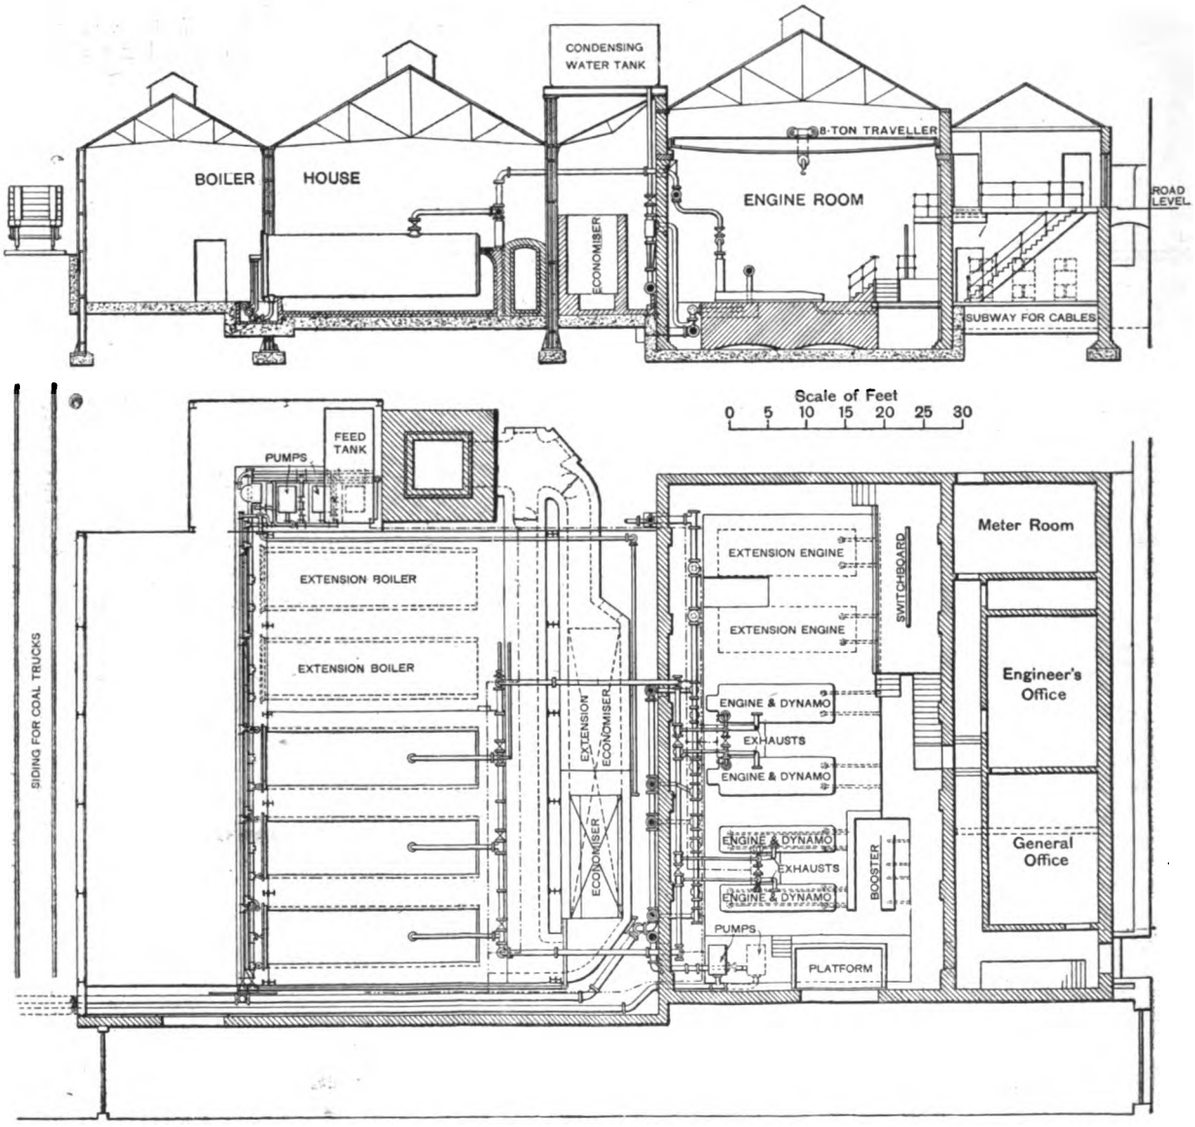
CARLISLE ELECTRICITY SUPPLY STATION.

The Carlisle central station, which will shortly be put into operation, is of Prof. A. B. W. Kennedy's design. At present it will only serve for the lighting of the town, but it is proposed to erect an electric tramway system which will be fed from the same station. The system adopted is the three-wire system, with an earthed middle wire and 460 volts between the outers. Steam-driven balancing dynamos are used, and a battery. The boosters are arranged so that they can be used in series with the cells, and add to the voltage of the dynamo during charge and to the voltage of the cells during discharge.



Plan and Sectional Elevation of Carlisle Central Station.

During light loads the voltage is regulated by cutting cells in or out, and the cell-regulating switch is interlocked with the booster reversing-switch by a special arrangement designed by Prof. Kennedy, which facilitates the switchboard attendant's duties and ensures against error. This is one new feature of the Carlisle station; another exceptional feature is the provision to be made for utilising the dynamos either for the 460 volts lighting network or the contemplated 500 volts tramway system. For the former purpose they are used as shunt machines; for the latter a series-winding is added, and they run compound. The arcs used for public lighting are connected 10 in series across the 460 volt mains.

The station is situated at the corner of James-street and the Victoria Viaduct, and has the advantage of a siding from the Caledonian Railway. The plan and sectional elevation show the general arrangement of the station and the disposition of the machinery and plant.

The boilers are of the Lancashire type, 28ft. by 8ft., manufactured by the Oldham Boiler Works Co., each with two internal furnaces, 3ft. 8in. external diameter. A working pressure of 160lb. per square inch will be employed. The steam-pipe connections are shown in the illustration; it may be mentioned that in their erection this arrangement was departed from, but to a very slight extent only. The main lines of pipe are 8in., and are of steel, while all the bends and all the pipes of 4in or less in diameter are of copper. A Green's economiser is employed.

The condensing water pumps are electrically driven, the water being obtained from the river. Four Ledward ejector condensers are used, two capable of dealing each with 4,000lb. of steam per hour, and two dealing with half that quantity. In these condensers Messrs. Ledward have not departed from their standard pattern.

The two main steam dynamos are of the Willans-Siemens type, running as shunt machines at 330 revolutions per minute, and generating 255 amperes at 490 volts (maximum), or as compound machines at 350 revolutions when they are capable of giving 227 amperes at 550 volts. These are supplemented by two pairs of balancing dynamos, each pair being coupled to a Willans engine. Each dynamo of these

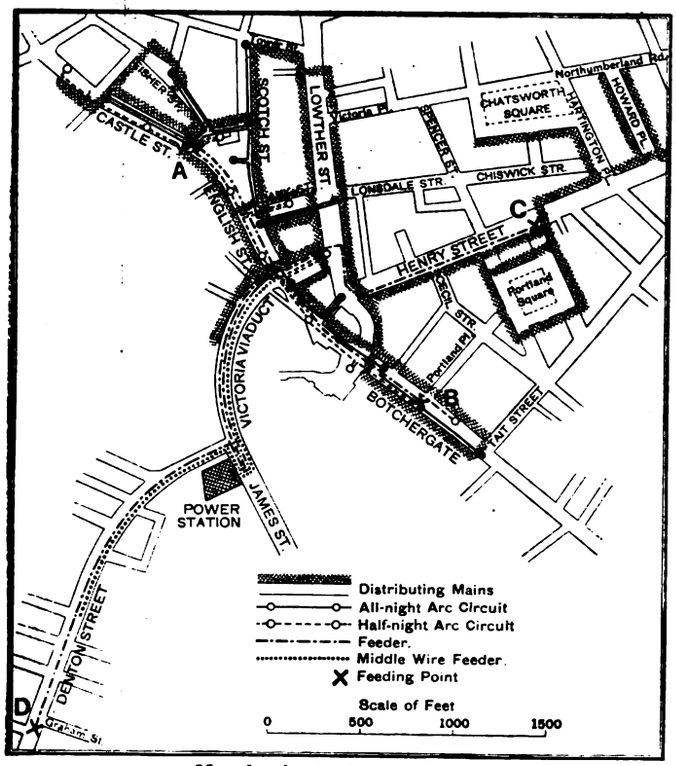
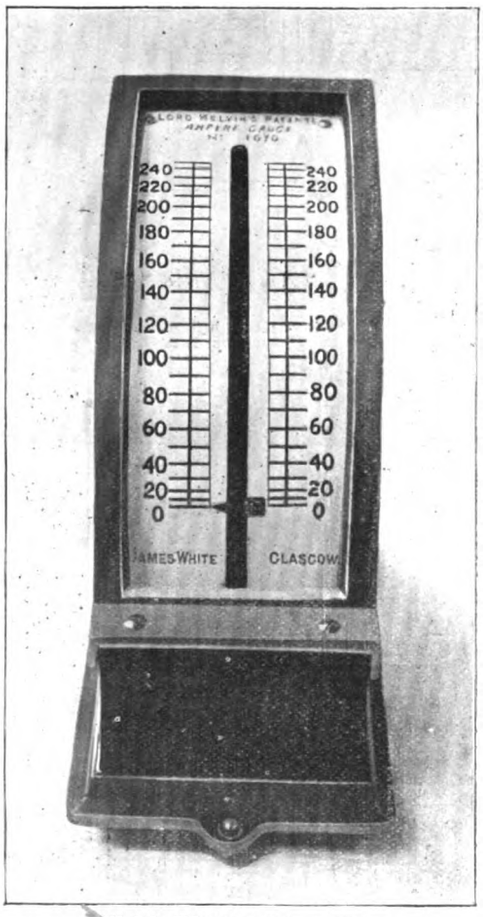
"double-enders" will generate 128 amperes at 245 volts when running at 450 revolutions per minute. There is nothing exceptional to remark in either of these machines.



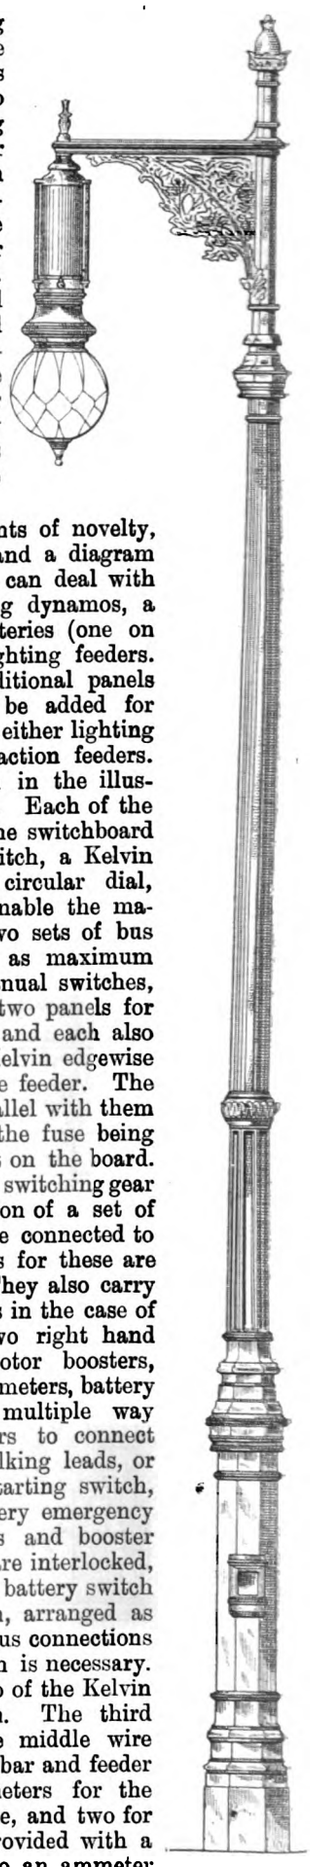
Map showing Positions of Mains.



Kelvin Edgewise Ampere Gauge.

The booster, shown in the illustration, consists of three upright bipolar machines, of the Electric Construction Co.'s standard type, mounted together in line on a substantial bedplate, which carries four self-oiling bearings; the centre machine is the motor which is shunt wound and is for an E.M.F. varying from 460 to 520 volts; it provides the driving power for the two outer machines or boosters proper. These are each capable of giving any current between 0 and 60 amperes at any voltage from 10 to 70 volts, with capacity for a maximum load of 120 amperes. The dynamo armatures are connected to the motor armature by flanged couplings for easy separation and removal. As already mentioned, the booster will be used principally for charging and discharging the battery when the E.M.F. at the omnibus bars is either lower or higher than the E.M.F. of the battery.

The switchboard, having some points of novelty, we illustrate it by both an elevation and a diagram of connections. At present the board can deal with two generators, two sets of balancing dynamos, a motor with double booster, two batteries (one on each side of the system) and four lighting feeders. Provision is made so that two additional panels with necessary switching gear can be added for connecting the two main generators to either lighting or traction bus bars, and for two traction feeders. The proposed arrangement is shown in the illustrations, for the sake of completeness. Each of the main generators has in circuit on the switchboard a double pole automatic magnetic switch, a Kelvin sector pattern ampere gauge with circular dial, and plug bars. The latter are to enable the machines to be connected to either of two sets of bus bars. The automatic switches act as maximum or minimum cut-outs, and also as manual switches, and they have carbon breaks. The two panels for the main generators are on the left, and each also carries two feeder switches and two Kelvin edgewise ampere gauges on the two poles of one feeder. The feeder switches have connected in parallel with them a light fuse for breaking the circuit, the fuse being fixed in a convenient position, but not on the board. The balancing dynamos have the same switching gear as the main dynamos with the addition of a set of change over bars, so that they can be connected to either side of the system. The panels for these are the fourth and fifth from the left. They also carry feeder switches and ampere-gauges, as in the case of the main generator panels. The two right hand panels are for the batteries and motor boosters, and have mounted on them booster ammeters, battery ammeters, booster voltmeters and multiple way switches, motor ammeter, plug bars to connect the booster either to the battery, milking leads, or to a meter-testing circuit, a motor starting switch, booster field breaking switches, battery emergency switches, battery regulating switches and booster reversing switches. These latter two are interlocked, as has already been mentioned. The battery switch has 11 contacts and a double brush, arranged as in the diagram. From this the various connections are evident, and no further description is necessary. The ammeters on these panels are also of the Kelvin type, and the voltmeters are Weston. The third panel from the left is devoted to the middle wire instruments, and to the dynamo, 'bus-bar and feeder voltmeters. There are four voltmeters for the dynamos and bars, of the Kelvin type, and two for feeders of the Weston type, each provided with a double-pole multiple way switch; also an ammeter for the middle wire and one for the earth connection. The panels are of slate, 2in. thick, enamelled back



Arc Lamp Post for Carlisle Public Lighting.

Digitized by Google

and front. The frame work is built up of steel tees and angles; it is 17ft. long, 7ft. 3in. high, and is surmounted by an eight-day clock.

All the feeder ampere-gauges are of Lord Kelvin's edgewise sector pattern, with scales, as shown in the illustration. The principle of this instrument is the same as that of Lord Kelvin's ordinary sector pattern ampere-gauge. These contain a solenoid giving an exceedingly intense and uniform field, this solenoid being so constructed that the axis of the field passes through the axis of the solenoid. Into the solenoid is entered a soft iron plunger suspended from an aluminium sector which, together with the pointer and suspension bar, forms the movable system. The current passing in the solenoid attracts into it the soft iron plunger, and this movement is indicated by the pointer on the scale. The zero is at the bottom of the scale; and an increase of current is shown by a rise of the pointer. These instruments are fitted in strong cast cases with nickelled facing, forming a thoroughly substantial piece of apparatus, and at the same time having the accuracy of reading of a high-class instrument. The Kelvin voltmeters are of the small dial engine-room type, a special feature in which is a short scale giving only the part of range that is required, and consequently very large divisions.

To avoid crowding the diagram, all the connections to the voltmeter switches A, B, C, D, E and F are not shown in the plan of connections. A and D can connect their voltmeters to either of the main generators, 3 and 4, A on the dynamo side of the cut-out and B on the 'bus bar side. They can also be connected between the top and bottom 'bus bars respectively. B and E can be connected in the same way to the balancing dynamos, A, B, C and D, B on the dynamo side of the cut-out and E on the 'bus bar side. B can also be connected between either positive 'bus bar and the middle wire, while E in a similar way on the negative side. Lastly, B and E will also give the voltage between cell 125 or cell 115 and the top negative and positive 'bus bar respectively, inside the battery switch. C and F in their lower positions connect their voltmeters between the booster terminals, in their left-hand positions between the terminals of the positive battery and emergency and regulating switches respectively, and in their right-hand positions between the terminals of the negative battery and the regulating and emergency switches respectively.

There are two batteries, each of 125 Chloride cells, at the station itself. The minimum capacity for a five-hour discharge was specified to be 800 ampere hours, and the cell was to give without derioration 90 amperes for three hours, or 120 amperes for 30 minutes, in each case without a lower E.M.F. than 1·86 volts per cell being attained. The cells are in glass boxes and supported, as usual, on oil insulators.

The map given shows the course of the mains, the situation of the feeding points, arc lamps, &c. All the cable is of the Callender lead-covered and armoured type, laid direct in the ground. The distributors are of uniform size, viz., triple concentric with conductors 0·12, 0·12 and 0·06 sq. in. in section. The latter is, of course, for the neutral wire, which forms the

Digitized by Google

outer conductor of the cable. The feeders are ordinary concentric, all of 0·25 sq. in. section, and the neutral wire feeders, two in number, are single armoured cable with a similar conductor section.

There are in all 25 arc lamps, erected on cast-iron bracket pillars of the design shown in the illustration. The pillars are placed along the edge of the footpaths with the brackets and lamps overhanging the roadway. The lamps are run in three circuits, two consisting of eight lamps in series and the other one of seven. Current is taken from the outside conductors of the three-wire network at a pressure of 460 volts. They are constructed so as to burn 10 in series on this pressure, as is done at Edinburgh. Consequently, it will be possible to introduce five more lamps into these three circuits at a later date. The lamps are of the Crompton-Pochin type, with single carbons, and they will burn for 18 hours without retrimming. The current is 10 amperes. The pillars were supplied by Messrs. Mackenzie Bros., and the lamps, &c., by Messrs. Crompton.

In the base of each pillar is fixed an automatic cut-out and substitutional resistance, so arranged that, in the event of a lamp "hanging up," or the carbons burning out, the remainder of the circuit is not interfered with. A single-pole switch and fuse is provided at each end of each circuit. These, with the line steadying resistances and other fittings, are fixed inside the base of the poles.

In concluding, we wish to acknowledge our indebtedness to Prof. A. B. W. Kennedy, and some of the contractors, who have afforded us material assistance in the preparation of this article.

AN IMPERIAL CABLE SERVICE.

Sir Sandford Fleming has addressed a communication to Mr. Chamberlain urging the adoption of a system of State-owned cables for the empire.

Sir Sandford Fleming instances in support of his arguments the success which has attended the change from a telegraph service managed by private companies to a telegraph service owned by the State and administered under the Post Office department. Before the transfer complaints were frequent and well founded as to the inefficiency of the telegraph service, and the business done was much restricted. After the transfer and the reorganisation of the service by which it was accompanied, the public gained the advantage of cheap messages, and business developed to such an extent that receipts progressively increased. We can as yet (he points out) but faintly appreciate the extent to which the telegraph may be employed, because its use heretofore has been restricted, on long-distance messages, by almost prohibitory charges. If messages be exchanged between places not far apart, let us say between London and Edinburgh, or Toronto and Montreal, the gain in time by the use of the telegraph is inconsiderable. But if the points of connection be far separated, such as London and Melbourne, or Ottawa and Cape Town, the comparison between a postal and a telegraph service brings out the distinct value of the latter. Were the cables owned by the State large profits would not be the main object, and, precisely as in the case of the land lines of the United Kingdom, it would be possible to reduce charges so as to remove restrictions on trade and bring the service within reach of many now debarred from using it.

When the Government assumed control of the inland telegraphs of the United Kingdom it was found possible to greatly reduce charges. In 1869, the year before the transfer, less than seven million messages were carried. At the transfer the rate was reduced to 1s. per message; the traffic immediately increased nearly 50 per cent. and continued increasing until, in the tenth year, 29 million messages were transmitted, with a surplus of revenue over expenditure of £354,060.

The system of Imperial cable construction put forward for adoption by Sir Sandford Fleming would have for its object to complete the telegraphic circuit of the globe and to "constitute a base for connecting every one of her Majesty's possessions and naval coaling stations (Gibraltar and Malta excepted) by the most perfect means of conveying intelligence at our disposal." He divides the proposed cable system into three sections, one of which would be composed of cables in the Pacific Ocean, one of cables in the Indian Ocean, and one of cables in the Atlantic Ocean. The cables in the Pacific Ocean would start from Vancouver and find a first mid-ocean station at Fanning Island, a second at Fiji, and a third at Norfolk Island. From Norfolk Island it would bifurcate, one branch extending to New Zealand and one to the eastern coast of Australia. Telegraphic communication across the continent would put it in touch with King George's Sound. The cables in the Indian Ocean would start from King George's Sound and find mid-ocean stations at Cocos Island and Mauritius, extending thence to Natal or Cape Town. From Cocos Island connection would be made with Ceylon, Singapore, and Hong Kong. From Mauritius connection would be made to Seychelles, Aden, and Bombay. The cables in the Atlantic should extend from Cape Town to Bermuda, finding mid-ocean stations at St. Helena, Ascension and Barbados. From Bermuda connection would be made with Halifax and the existing Canadian and Trans-Atlantic lines. The total distance for which under such a scheme new cables would be required is estimated by Sir Sandford at 23,000 knots, and the approximate cost of construction at from £5,000,000 to £6,000,000. One advantage of completing the circuit of the Empire by a round-the-world system of British cables, upon which Sir Sandford Fleming lays special stress, is that each point touched "would be in connection with every other point by two routes, extending in opposite directions," thus practically constituting a double connection in each case.

ELECTRICITY WORKS ACCOUNTS.

Southport Municipal Electric Supply Works.

Inaugurated November 17, 1894, the electric supply undertaking at Southport is maintaining steady progress, and stands in a satisfactory position as regards economy of working in relation to undertakings of similar magnitude. The authorised capital is £58,822, all of which has been borrowed at 3 per cent., while £3,010 has been repaid. At March 31 last the total expended capital amounted to £63,057, representing £93·8 per kilowatt of generating capacity of plant.

Comparing the business of 1897-8 with that of the preceding year we find that with an increase in the number of consumers of from 225 to 338 the equivalent 8 c.p. lamp connection has risen from 16,671 to 26,012, or 56 per cent. The total output for the year 1897-8 being 876,490 shows an increase over that of 1896-7 of 53·4 per cent., while the supply to private consumers indicates an increase of no less than 93 per cent.

In consequence of a reduction in the price charged the average revenue received per unit has dropped from 4·813d. to 4·268d. The total costs per unit have been substantially reduced through all the items of cost except establishment charges and repairs and renewals of mains and at the station. The year's working shows a decreased ratio of costs to revenue and a working profit of £3,523, representing 6·24 per cent. of the mean capital. This profit has been disposed of by a payment of £1,416 in interest on loans, £1,488 to the sinking fund, and £195 in wiping out the previous year's adverse balance, leaving a balance for 1897-8 of £475 to be carried forward.

The Local Government Board have sanctioned a further loan of £21,178 for electric lighting extensions.

Whitehaven Municipal Electric Supply Works.

Whitehaven, even to a greater extent than Southport, enjoys the effect of a relatively high proportion of public and contract lighting, and moreover the use of batteries tends further towards giving the high "plant load factor" (as measured by the ratio of the units sold to the plant capacity) of 28·8 which has obtained during 1897-8.

Supply having started in September, 1893, our analysis includes the fourth completed year of working. The whole of the authorised capital of £19,004 has been borrowed—£4,213 at 3½ per cent. and £14,791 at 3 per cent. interest, while £1,263 has been repaid (at 3½ per cent.). The expended capital has amounted to £18,667, being at the rate of £88·9 per kilowatt of generating plant. So far as the accounts rendered to us are concerned, Whitehaven appears to have lost the three opening months of 1897 without a record of existence during that period.

The increase in the total output sold has been barely 6 per cent., while the average revenue per unit and the total costs have both risen. The works costs have, however, been slightly reduced, and the figures for the costs are very satisfactory for the output, being below the average.

Out of the working profit of £1,647 which has been made, representing 8·96 per cent. of the mean capital, £792 has been paid into the sinking fund, and £538 as interest on loans, leaving a balance to the good, carried forward, of £316.

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal 1861—1878).

Published every Friday, Price Sixpence; Post Free, Sixpence Halfpenny

Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone: 949 Holborn. *Telegrams:* "Electrician Newspaper London."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "The Electrician," Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to "The Electrician" Printing and Publishing Company, Limited, and be crossed "Coutts and Co."

All Editorial letters to be addressed to The Editor.

All letters for insertion in "The Electrician," or containing questions, must be accompanied by the name and address of the writer as evidence of good faith. No notice whatever is taken of anonymous communications.

"The Electrician" is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices, as above.

New Volumes of "The Electrician" commence in April and October.

Subscription Rates.—The Rates for Subscriptions to "The Electrician" are as under:—

	Year	Half-Year	Quarter	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d	

"The Electrician" offers exceptional advantages to Advertisers. It has by far the largest circulation of any English Electrical paper, and circulates all over the World. *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

Trade Advertisements *intended for the current issue must reach the Office not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday. Wrapper Advertisements by Wednesday morning.*

Official Announcements, Auctions, *and* Small Advertisements *accepted up to 6 p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct o "The Electrician" Printing and Publishing Company, Limited. The well-known "Electrician" Series of Standard Electrical Works at present consists of—

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young, M.I.E.E. Price 10s. 6d., post free; abroad 11s.

THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By Messrs. H. K. C. Fisher and J. C. H. Darby. Price 6s. net; abroad, 6s. 3d.

BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH. Edited by C. E. S. Phillips. With an introduction on the history of Crookes Tube and Röntgen Ray work, and a chapter giving "Practical Hints," on the subject.

THE POTENTIOMETER AND ITS ADJUNCTS. By W. C. Fisher. Price 6s., post free.

LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS. By F. C. Raphael. Price 5s., post free.

MOTIVE POWER AND GEARING. By H. Trueliet Carter. Price 12s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson. Price 12s. 6d., post free.

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. Fleming, M.A. F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d., post free 12s. *Vol. II. is nearly ready.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. Fleming. VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. New Edition. Price 12s. 6d., post free. VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. 93 original illustrations, price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. Snell. 10s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. George Gore. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. Weymouth. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By Gilbert S. Ram. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Gruphl and H. M. Kilgour. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d., post free. New edition in the press.

"THE ELECTRICIAN" PRIMERS. In Two Vols. Paper covers, 2s., post free, 2s. 2d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d.

WIRELESS TELEGRAPHY: Signalling across Space without Wires by Electric Waves. By Dr. O J. Lodge. Enlarged Edition. Price 2s. 6d. net.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c. By A. C. Curtis-Hayward, B.A. Price 3s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont. Price 2s. 6d., post free.

FULL CATALOGUE POST FREE ON APPLICATION.

"ELECTRICIAN" SERIES FORTHCOMING BOOKS.

ELECTROMAGNETIC THEORY, VOL. II.—By Oliver Heaviside. The second volume of this important work is in an advanced stage, and will be ready shortly.

PRACTICAL TELEPHONY.—By Dane Sinclair and F. C. Raphael.

PRIMARY BATTERIES.—A work on this subject will shortly be published, bringing the theory and practice of the Primary Battery up to date. The book will be fully illustrated.

SECONDARY BATTERIES.—By E. J. Wade. Fully illustrated. The Author in this work will deal briefly with the theory and fully with the chemistry, design, construction and manufacture of secondary batteries or accumulators.

"THE ELECTRICIAN" WIREMAN'S POCKET-BOOK.—"The Electrician" Company will shortly publish a valuable pocket-book for the use of those engaged in wiring work, both external and internal.

CARBONS FOR ALL ELECTRICAL PURPOSES.—By Francis Jehl. A work will shortly be published dealing fully with the manufacture of carbons for all electrical purposes. The book will illustrate the machinery and apparatus used in carbon manufacture on the Continent and in America, and will give the latest practice in this important subject.

THE ELECTRIC ARC.—By Mrs. Ayrton. This work will shortly be published, and will contain an historical sketch of the early experiments on the electric arc, as well as the important results of recent research.

SPECIAL NOTICE.

NOW READY.—Vol. XLI. of "The Electrician," bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

A complete set of the Second Series of "The Electrician" can now be supplied. These sets are very scarce, and early application should be made.

COMBINED ELECTRIC TRACTION AND SUPPLY STATIONS.

We publish in our issue this week descriptions of the electric power stations at Cork and Carlisle, the first named of which has recently commenced working, while the other will shortly be put in operation. These two power stations may, in some respects, be regarded as being each the converse of the other, inasmuch as the station at Cork is primarily a tramway station equipped so that it can also generate current for electric lighting, while the Carlisle station is essentially an electric supply station with arrangements for working tramways at some future date in the event of electric traction being adopted in that town. Though at first sight the difference between these two conditions might appear to be more of a distinction than a real difference, yet from an engineering as well as from a commercial point of view there is an essential difference. It has been boldly asserted that it will pay an electric lighting concern to undertake electric traction, but that it will *not* pay an electric traction undertaking to supply current for lighting. The reason is to be found in the fact that an ordinary town tramway load is fairly uniform over very many hours in each day, and is, therefore, highly remunerative, whereas the characteristic peak of an electric lighting supply load tends to rob the electric supply undertaking of much of the profit that it would make if it could have a uniform load over many hours. A combination of the two, generally speaking, is, therefore, an advantage to an electric supply undertaking, though it might be, and, in some cases, is, a disadvantage to a tramway concern. Widely different views have been expressed in the electrical profession in regard to the advisability of imposing a lighting load on a tramway station, and as to the converse case of imposing a tramway load on a lighting station. It has been said, for example, that the ordinary town traffic puts a tramway peak on to the station at about the same time that the lighting peak occurs, and that

Digitized by Google

therefore the combination produces no advantageous results. This view is, in our opinion, largely imaginary, as the tramway peak, where it exists at all, is by no means as large in proportion to the average load as is the case with a lighting peak; and in the vast majority of cases the effect of an ordinary tramway load from early morning till late at night is to improve considerably the load factor of a lighting station. With regard to the converse case, of a lighting load being put upon a station primarily and essentially designed for tramway work, there are several aspects to be considered. It is probable that a tramway company with a very extensive network of lines over which a frequent service of cars is running, would generally find the hours sufficiently long and the load sufficiently uniform to produce the best paying results; and for such a company the burden of supplying current for lighting during the evening would certainly be no advantage; indeed, it would be a positive disadvantage. On the other hand, there are many places where the tramway service puts a maximum load on the system during the hours of daylight, and where the load appreciably falls after dark. In such circumstances the addition of a lighting load would extend the hours of useful work in the power station, and would therefore increase both the turn-over and net profit of the undertaking. There is another case that merits consideration, viz., where instead of a limited liability company the local authority owns and works the lighting and tramway business. When this is the case, in the vast majority of instances, it would be far more advantageous in all respects for the authority to erect one combined station rather than to have two independent stations, one for the tramway and the other for the supply business.

Having decided upon a combined station, there remains to be settled many questions of detail as to the manner in which the combined plant is to be arranged. In not a few large power stations the load on the generators at any one moment is of a mixed character, consisting of lighting, tramway motors and ordinary consumers' motors. But this practice has not found favour in England. Indeed it is probable that the small magnitude of the loads on combined stations in this country would render it inadvisable to combine the loads on actually the same generators. Going to the opposite extreme some combined stations have been designed with two sets of plant, one exclusively for the supply, and the other exclusively for the tramway current. The more recently designed stations, however, have been provided with generators, each of which may be switched on to either the lighting or the tramway circuits, two separate sections of the switchboard controlling the feeders for these two departments. This is, in our opinion, the best arrangement in average circumstances, providing, of course, that the supply is to be from low-pressure continuous-current generators. Where alternate currents or polyphase currents are concerned, the problem is more complicated. In both Cork and Carlisle the arrangements are for continuous-current generators supplying direct either to the tramway or lighting circuits. A point which presents some little difficulty at the outset is the pressure,—the pressure required for tramway generators being somewhat higher than what would be necessary to produce the Board of Trade limit of low pressure in the consumers' network. This difficulty, however, is very satisfactorily surmounted by means of the extra excitation which the series windings give to the railway generators, these windings not being used when the generators are employed for the ordinary supply. Thus, when working on the lighting circuit the generators are regulated exclusively on the shunt magnet coils, but when used for running the tramcars the shunt excitation is brought up to a higher pitch and the series windings are thrown in so as to over-compound the generators for about 10 per cent. fall on the feeders at maximum load. For instance, at Carlisle the ordinary pressure on the consumers' mains is 460 volts between the outers, while for the tramway supply at top load a generator pressure of about 550 volts would be required. The difference in generator pressure is well produced by means of the change from shunt to compound excitation, as just explained.

With the rapid extension of electric traction and electric supply in the United Kingdom which is noticeable at present, and with the marked disposition of local authorities to acquire and exercise powers to work both these classes of undertakings, the problems associated with the combined electric traction and power station will come more and more prominently to the fore. As these problems present themselves to manufacturers and consulting engineers engaged in designing stations, they are bound to influence and modify the practice in the design of power station plant and details. Generators capable of undertaking both classes of load, even better than those now on the market, will certainly be evolved ere long; and it would seem that the multiplication of this class of station will ultimately lead to the abandonment of the two-pole form of continuous-current generators, so popular in stations a few years ago, and the substitution for them of the large multipolar generator, approximating in character to the railway generators now so extensively employed on the Continent and in America.

CARBONS FOR ELECTRIC LIGHTING AND OTHER PURPOSES.*

BY FRANCIS JEHL.

(*Continued from page 219.*)

Fig. 33 shows the construction of a modern gas generator (as given by Prof. A. Ledebur.)†

It is largely used also in connection with Siemens furnaces, and is adapted for small coal, especially for brown or mineral coal, which gives plenty of gas. Fig. 34 is a vertical section and plan. It will be noticed that two of the sides of the generator are vertical, while the front and back sides are inclined. The inclination depends upon the material used as fuel, and may be from 50deg. to 70deg., according as the latter is compact or loose. The fuel is thrown into the generator at *a* by raising the covers, and *b* are openings that serve for stoking and keeping the fuel evenly divided on the grates. One of the grates, as will be seen from the figure, is a plain one, while the other is of the "step" form, thus insuring a large surface, which is necessary when small coal is used. The air arrives from the blower at *c*, while *d* is a door which is kept closed when the blower is in action, and serves also for taking the ashes away. The gas that is generated goes into the passage *h*, when the valve *e* is raised by means of the wheel *f*. It will also be noticed that the whole generator is built below the surface of the ground, with only a space open at the front in order to get at the ashes, &c. This affords a convenient way of supplying fuel to the generator as the openings *a* are on the ground level, while there is little heat dissipated through the sides, as they are banked with the earth, which is a bad conductor. The dimensions marked in the drawing are in metres.

Fig. 34 shows the construction of a gas generator that H. Stegmann says is adapted for nearly all kinds of solid fuel with the exception of earthy brown coal. A noticeable feature of this generator is the grate, seen in the illustration. Of course, when using a blower, it is necessary to have a door in

† "Gasfeurungen," A. Ledebur.

Digitized by Google

front of the grate. The advantages of such a form of grating is that there is a constant tendency of the fuel as it gets consumed to shift downward, while the ashes, &c., get pushed towards the opening between the grate and the back of the generator, from whence they can be easily dislodged. A small

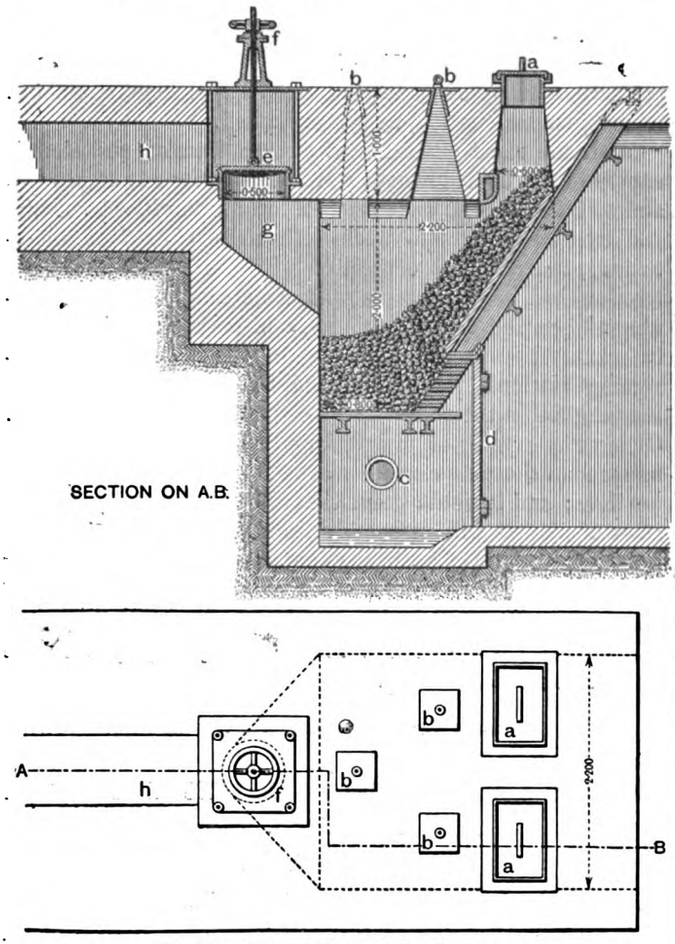

FIG. 33.—General Form of Gas Generator.

opening at the top of the generator (not shown in the illustration) serves for stoking purposes when necessary.

It has, however, been found in practice that fuel which cakes and swells up a great deal does not give general satisfaction when used in the generators that have been so far described. The generators that are built especially for such kind of fuel have generally the form shown in Fig. 35. It will be noticed that the lower portion of the generator is of a plain, cylindrical form, while the upper part tapers inwards, as

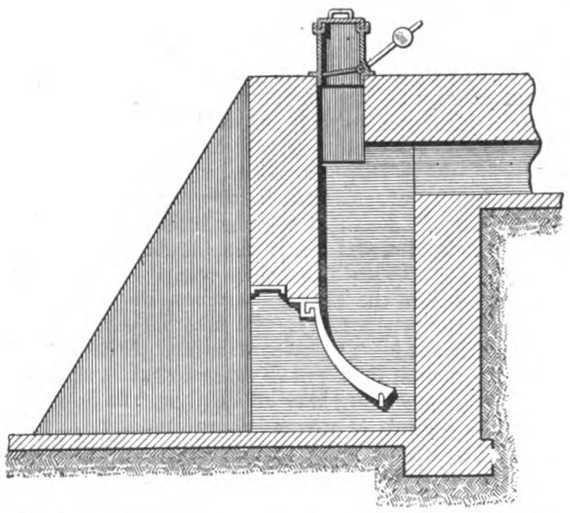

FIG. 34.—Gas Generator adapted for different kinds of Fuel.

shown. Such generators were built by Sailler for the Witkowitz works, where they use coal that cakes very much, and have given satisfaction with the fuel used. As seen, the generator has no grate; but there are simply two openings, *a a*, at the bottom, which are stopped up with plugs of earth when the generator is in action. From time to time these plugs are withdrawn, and the fused slag is allowed to run out. Around the lower part of the generator there are two grooves, *b b*, in which water circulates for cooling purposes, as that part of the generator gets very hot. The air which is supplied from blowers is led into the generator at two sides by the nozzles *c c*, which are also placed in a cooling box, shown by the shaded portion at the lower part of the generator. At the top there are a couple of stoking holes, *d d*, while *e* is the passage into which the gases generated flow, and *f* is a device for supplying fuel, similar to that already explained. It is said that, with an air pressure of about 10cm. to 20cm. on a water manometer, the gas generated does not contain more than 1 to 2 per cent. of carbonic acid gas, while the tempera-

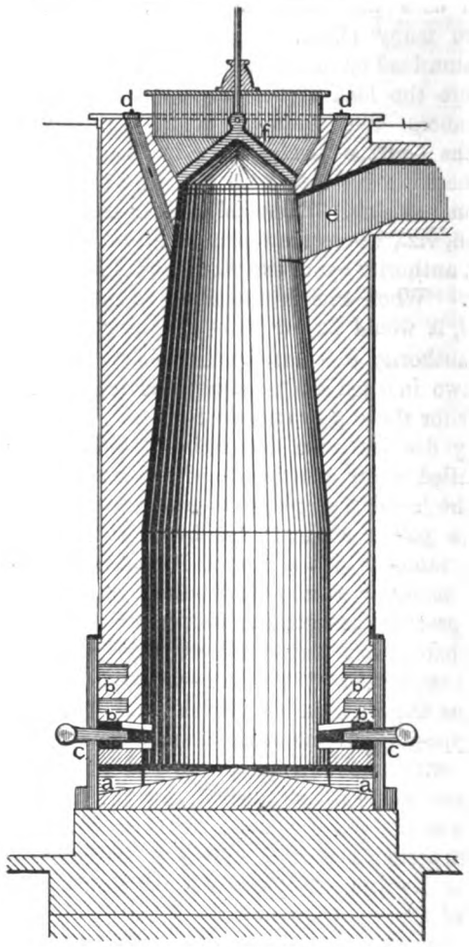

FIG. 35.—Gas Generator for Caking Fuel.

ture at which it leaves the generator is from 700°C. to 900°C. Nor is there any distilled matter obtained, as the gases are so hot when they reach the furnaces that the volatile matter cannot condense.

According to Steinmann, the total grate surface of a generator should not exceed two square metres, and if more gas is wanted than one generator can produce, two should be used, as large generators do not work well. The space between the grates should be about $\frac{1}{4}$ to $\frac{1}{3}$ the total grate surface in a plain grate, and $\frac{1}{2}$ to $\frac{3}{4}$ in those of the step form. Prof. Ledebur states that upon one square metre of grate surface about the following amount of fuel should be supplied per hour: mineral coal about 40 to 50 kilogrammes, and if there is a strong draught about 60 kilogrammes, coke 60 to 80 and peat 100 kilogrammes.

The height of the fuel in a generator may be about 0·6 metre with small brown coal, 0·7 metre with large brown

Digitized by Google

coal, 0·75—0·8 metres with mineral coal and coke, while 1—1·5 metres with peat and wood. It is almost needless to state that every generator should be supplied with some safety device, so that in case of an explosion the expanded gases may find an easy path for egress.

In concluding this chapter on generators the writer wishes to point out what an advantage over other countries the United States and Russia possess, as they have enormous wells of natural gas, and gas generators are, of course, not necessary where natural gas can be obtained. There is thus a saving in attendance, while at the same time the flow of gas is far more regular than can be obtained from a generator which depends upon cautious manual management. Natural gas has another important advantage. That obtained in the United States contains much less inert gases than that generated in a generator, and, therefore, per weight or volume it will give more thermal units than the gases produced in a generator, so that the natural gas is better adapted for obtaining the high temperature necessary in baking carbons. The gases generated in a gas generator may have, under good conditions, 35 parts in volume of fuel gases, the remaining 65 parts consisting of nitrogen, carbonic acid gas, &c., while natural gas contains more than 80 per cent. of fuel gas. The components of natural gas are: Methane (CH_4), hydrogen (H), ethylene (C_2H_4), ethane (C_2H_6), carbonic acid gas (CO_2), and nitrogen (N).

VII. The Furnace.

In considering the furnace or oven in which the gas is burnt, it may be remarked that the same is, in reality, nothing more than a simple chamber or part of one, in which the gases and air meet, get mixed, and then burn, while the resulting gases that are produced by the combustion leave at the opposite end. The principal object to be attained in such a combustion chamber is to effect a complete burning of the combustible gases, that is, the combustible hydrocarbon gases should all be transformed into carbonic acid gas. To obtain complete combustion, we must have a sufficient and well distributed supply of air, also a high temperature which facilitates the chemical action resulting from the mixture of oxygen and the combustible gases. One of the most important objects to attain is to get the gases and air well and proportionately mixed, as otherwise we obtain an incomplete combustion. The writer may cite the two cases of an illuminating gas jet, and a Bunsen burner, both of which, let us suppose, consume the same quantity of gas. The heat given out by a gas jet in such a case is considerably less than that of the Bunsen burner, where the gas and air get well mixed before burning, whereas, in a gas jet, there is only a sort of lateral mixing of air and gas. We see also that a much better mixing of air and gases can be obtained, when the gases are supplied from a generator or gas well, than when using an ordinary grate furnace where the fuel is directly burned and converted into heat.

From these facts we conclude that an ideal furnace, especially for the carbon industry, would be one in which the gases issue from a large number of jets, which permits a better and more perfect mixing with air, while at the same when only one or a few jets are used. In fact, it has been time the heat produced will be more evenly distributed than demonstrated that when a certain quantity of gas is consumed, a better thermal efficiency is obtained when using many jets than when using a few. Another important thing to attain when burning gases in an oven or furnace is regulation, that is, to regulate the quantity of gas so that it flows out of the jet or burner in proper proportion. By using the word "jets or burners" the writer refers to the openings in furnaces from which the gases or air issue.

It may be mentioned that Frederick Siemens maintains that it is necessary for each flame to have a certain space in which it can expand, as otherwise there will not be a complete combustion. His assertions are based upon the theory, that combustion depends upon a sort of molecular motion, and that this motion is rendered difficult when gas and air come into contact with fixed bodies, where either attractional or frictional resistance is experienced. Practice has confirmed the above, as it is found that furnaces with a very small combustion space, in which the flames always strike or come in contact with the sides, do not give as much satisfaction as those furnaces having a correspondingly larger space.

To obtain a high temperature in a furnace it is necessary to have the air heated before it is mixed with the combustible gases. It is evident that when cold air is supplied a large quantity of heat is absorbed and taken from the fire, which heat would have otherwise been used for a more direct purpose. Mr. Neilson, of Glasgow, was no doubt the first to propose the hot blast—that is, to heat the air used for combustion before it reaches the furnace. His contrivance consisted of a series of pipes that were maintained at a high temperature either by means of a separate furnace, or by using a portion of the waste heat of the blast furnace itself. It was, however, in this direction that William and Frederick Siemens in 1860 made their epoch-making invention of what is known as the "regenerator." This invention consists simply of a chamber that is filled up with fire bricks so piled upon each other as to allow the heated gases of combustion to circulate freely around them before passing into the flue and out at the chimney. Generally, in practice two such chambers are provided; as soon as the bricks in a chamber are red-hot the combustion gases are switched over to the cold chamber in order to heat it. The air necessary for combustion is allowed to pass into the furnace by way of the hot chamber, and thus its temperature is raised to about 600°C. or 700°C. before it mixes with the combustible gases, thereby making it possible to obtain a very high temperature. As soon as this chamber is cooled down somewhat, the other chamber, which in the meanwhile was heated, is switched on to the air passage again. Thus, by forcing the air always to pass through one or the other hot chamber, a constant supply of hot air is obtained for combustion. In certain cases in practice the combustible gases are also forced to pass through such hot chambers, and thus air and gases arrive at the furnace with a very high temperature.

In such cases four chambers are necessary—that is, two pairs, each pair consisting of two chambers: one for the air and the other for the gases. These chambers are heated by allowing a portion of the waste heat to pass through each chamber. By this means it will be seen that a larger portion of the waste heat can be advantageously utilised again, and thus not only is a considerable economy in fuel obtained, but also a higher and steadier temperature. However, even when using a regenerator the waste heat escaping from a furnace may still be considerable, as tests have shown that the gases coming out at the chimney have sometimes a temperature from 400°C. to 600°C.

(To be continued.)

A DIRECT READING SYSTEM FOR MEASURING CURRENT LEAKAGE.*

BY DR. M. KALLMANN.

This system is based on the idea shown diagrammatically in Fig. 1. Suppose that ammeters A_I and A_{II} are placed in series with the positive and negative mains respectively; the number of lamps L burning will determine the current of J amperes which is flowing. If there is no leakage from either conductor the ammeters A_I and A_{II} would indicate J amperes. But if there is a leakage, owing, say, to faulty insulation of the negative conductor at the point y, and if we assume that the positive conductor in the remaining part of the network has an earth, x, of greater or less value—(an ideally high insulation is unattainable in practice)—an earth current, j, will flow from y to x, as shown in the dotted line. The readings of the two ammeters will then differ by j, the leakage current from the portion of the network under test. Now it would be impossible to observe such a small current as j by the difference between the two large currents J_I and J_{II}. It is, therefore, necessary to combine the two instruments in one, or, in other words, to use an ammeter with a differential winding. If this instrument shows no deflection, the insulation is faultless, but as soon as a leakage occurs its amount is indicated.

This method differs in the following important points from the other methods of measuring the insulation of light and power net-

* Abstract of a Paper read before the Verband Deutscher Elektrotechniker; *Elektrotechnische Zeitschrift*, October 13 and 20, 1898.

Digitized by Google

works :—(1) The leakage is shown directly as the actual loss of current that has taken place ; (2) it is independent of the earth potential ; (3) it is independent of the working pressure ; (4) it is independent of the load at the time of the measurement ; and (5) it is uninfluenced by leakage or earths on other parts of the system. The simplest way of applying this method is shown diagrammatically in Fig. 2. The resistance W is inserted in series with the conductor or system of conductors, the condition of whose insulation is to be tested, between the points 1 and 2 and between the points 3 and 4. Each of these points is connected through resistances e to one winding of the differential galvanometer g. This instrument may be a milli-voltmeter with two windings. In this

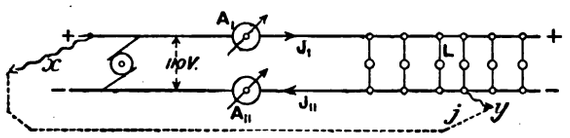

Fig. 1.

way, the readings of g will correspond to the difference of the two main currents i_1 and i_I. In place of a differential instrument, the connections of a Thomson's double bridge may be used as shown in Fig. 3, in which case the instrument g need only have a single winding. This combination requires no further explanation ; the reference letters and numbers in figures are the same as those used in Fig. 2. If the current i_I is equal to the current i_1, g will not deflect, as the points 5 and 6 will have the same potential, and the

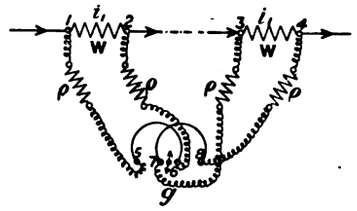

Fig. 2.

deflection g of the galvanometer again corresponds to the amount of current leakage between the points 2 and 3. In my system, therefore, the double bridge serves to compare currents and not to compare resistances. Instead of the convenient direct reading of G, one can, of course, bring the needle of the galvanometer back to zero by adjusting the resistance e. W,W need not either have the same value so long as W,W and e e on each side of the bridge have the same proportion to one another. These variations in the method are, however, not convenient in practice.

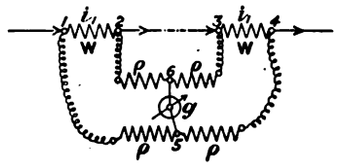

Fig. 3.

I will now enumerate the most important applications of my system. It may be used :—(*a*) to measure the leakage from a single feeder (Fig. 4) ; (*b*) to indicate the currents returning through earth from the rails of electric railways (Fig. 5) ; (*c*) to show the whole leakage current from a two-wire system (Fig. 6) ; (*d*) ditto from a three-wire system (Fig. 7) ; and (*e*) to measure the leakage currents from transmission lines to sub-stations.

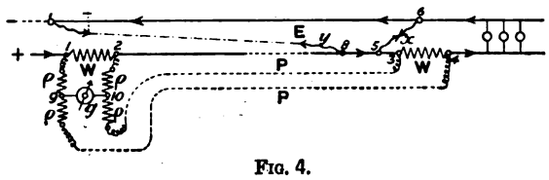

Fig. 4.

(*a*) The resistance W is inserted at the station end of the conductor to be tested between 1 and 2 (Fig. 4) and a resistance of exactly the same magnitude is inserted at the other end between 3 and 4. Assuming the conductor under test to be a feeder, from which no current is tapped between the points 2 and 3, the currents flowing from 1 to 2, and 2 to 3 will be equal if there is no leakage, and the galvanometer g will show no deflection. If there are a number of leakage currents, x, y, &c., their sum $x+y+\ldots$ will be indicated by the deflection of the galvanometer. Instead of a galvanometer or milli-voltmeter a signalling relay may be used by means of which the occurrence of a fault will be automatically announced. The resistance e e may be very small, so long as it suffices to compensate for the differences in resistance between the test wires P P.

(*b*) Fig. 5 shows the system applied to the rail returns conductors of electric railways. Lengths of rail, otherwise quite intact, must be used as substitutes for the resistances (*Hauptstromabzweigewiderstände*) W in the previous figures. In Fig. 5 the return current flows in the direction of the arrowheads through the length of rail S, and passes through the section 1, 2 (say 30 metres long), with a value of i_1 ampere. At a distance of some kilometres will be

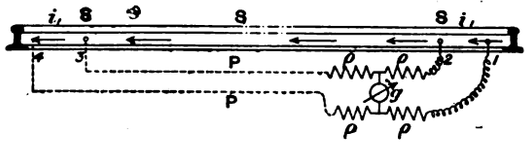

Fig. 5.

another length of rail, 3, 4, of the same profile, &c., through which the current will be i_I. A current of $i_1 - i_I$ amperes will, in fact, have branched from the rail circuit to earth between the points 2 and 3. This current will be indicated by the galvanometer g in the manner already referred to.

To give a numerical example, suppose, as the result of tests, the electrical resistance of a kilometre of heavy double rail to be 0·007 ohm. A length of 30 metres will have a resistance of 0·00021 ohm. A current, i_1 of 100 amperes (corresponding to six large cars) will cause a difference of potential of 0 021 volt between

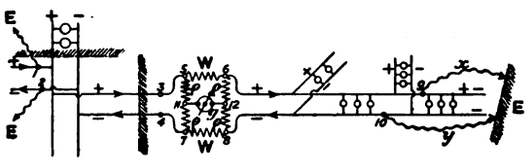

Fig. 6.

the points 1 and 2. If 20 amperes have left the rails between the points 2 and 3, the current i_I will only amount to 80 amperes, and the difference of potential between the points 3 and 4 will be 0 0168 volt. The leakage current to be indicated on the instrument g will, therefore, correspond to 0·0042 volt. Assuming 100 ohms for the resistance of the test-wires P and the compensating

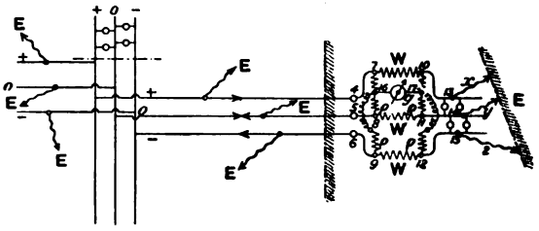

Fig. 7.

resistance e, and another 100 ohms for the resistance of the galvanometer itself, the current flowing through the galvanometer will be $\frac{0{\cdot}0042}{200+2} = 0{\cdot}0000105 =$ approx. 10^{-5} ampere. A Weston galvanometer with a pointer will give 1deg. deflection for 2^{-6} ampere, so

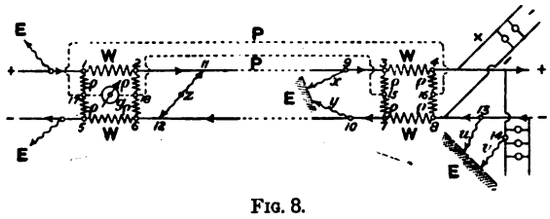

Fig. 8.

that in this case with 20 amperes earth-current 5deg. deflection will be obtained. With a mirror d'Arsonval more than ten times the deflection will be obtained. P.P may be the test-wires contained in the feeders, and their ends are to be connected to all four rails, preferably by means of the cross bonds.

(*c*) I now come to the method of connection to both poles of a network. Fig. 6 takes the case of a two-wire house installation connected to a supply network. The apparatus is connected where the service line is led in, resistances W being connected in series with it at 5, 6 and 7, 8, as shown. In the other parts of the net-

Digitized by Google

work there may be any earths 1, 2; let us assume that the earth on the negative pole is the more important. If in the house the positive pole at 9 has a lower insulation resistance than the negative pole 10, there will be a greater currrent flowing from the point 9 by way of x to the negative pole, and the current through 5, 6 will be greater than that through 7, 8. A sensibility of 1deg. per 10,000 ohms fault was obtained with a Weston galvanometer, and this can easily be increased by using a mirror instrument. However, the above sensibility is quite sufficient, as the apparatus is not intended for the insulation test, which must be made before the house is connected, but is meant to give a direct indication of the state of the insulation at any time afterwards, without disconnecting the house from the supply. Thus an indication is only required if the insulation has dropped to a given value; for instance, to some hundreds or thousands of ohms. The apparatus can either be continuously in circuit, and connected if required to an automatic signalling arrangement, or the two resistances W can be normally short-circuited by a double-pole switch.

The details of the apparatus (Fig. 9) will be referred to later, but it may here be mentioned that in the case of equality of the fault resistance of the + and − poles of the network, as well as of the installation, no deflection of the instrument g would be obtained. Although this coincidence is only to be expected on rare occasions, a test for it is easily possible by connecting a resistance of a few hundred ohms momentarily between each pole alternately and earth while taking the reading; the highest deflection obtained is then the determinative one. For even if, for instance, the leakage from the main network is not so intense at the time of the measurement, or if it is principally from the same pole which has a bad

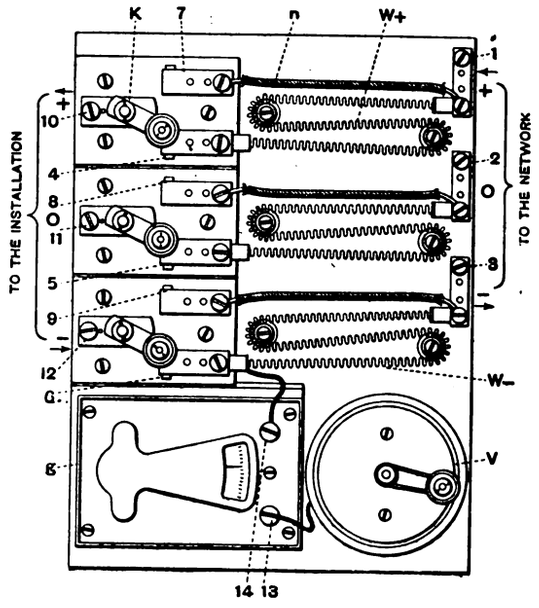

Fig. 9.

insulation in the installation, that is to say, if under the conditions the leakage current is quite small for want of large potential differences, the leakage is not inconsiderable in *every* case. Thus, if the leakage from the network changed in amount, or, above all, in polarity, a fault in an installation which was formerly quite harmless, can become dangerous. The leakage indicator described, when used in combination with an earthed resistance, shows clearly all these unavoidable fluctuations and changes in the condition of the insulation resistance of the whole network, as well as of the individual installation, which must always interact. As a particular case in point, consider a three-wire network whose middle wire is not earthed. A fault on the + wire of an installation, when the prevailing fault on the network is also on the + pole, is quite harmless; but if the latter fault be on the neutral wire, the fault in the house becomes serious, and if a bad fault on the negative pole of the network were to occur, the danger would be again considerably increased.

(*d*) The connections for a three-wire system, shown in Fig. 7, make it clear that the double-bridge arrangement can be extended to a system of any number of wires, without more than one instrument being necessary. The galvanometer g is connected to each of the three main resistances W in exactly the same way, and the system rests on the following:—If the current in the positive wire be i_+, that in the negative wire i_-, the current through the middle wire will be $i_+ - i_- = i_0$ amperes. The current i_0 passing through W on the middle wire at the points 8, 11, would, if there were no faults in the insulation be equal to the difference $i_+ - i_-$; and the galvanometer g which is connected equally across the points 7 and 10, 9 and 12, and 8 and 11 would show no current. But if an earth of x amperes occur, *e.g.*, at the point 13, this current x will also flow through the + resistance W from 7 to 10, but not through the other two resistances. The instrument g will thereupon show a reading corresponding to the difference $i_+ + x i_- - i_0 = x$ amperes.*

(*e*) The connections for many wire systems show how the apparatus is arranged for many sections in parallel; Fig. 8 is for a number in series. This diagram may be taken, for instance, to represent a case of long distance transmission with a sub-station. The generating station is to the left of the points 1, 2, where the transmission line begins, and the current passes in the customary manner through the resistances W at 1, 2 and 5, 6. A galvanometer g connected between 17 and 18 would, as in Fig. 6, indicate the leakage from the whole network to the right of the points 2 and 6, *i.e.*, from the transmission line and distributing network. It is not this test, however, but a separate test of the parts of the system that is needed. For this purpose a resistance, W, is inserted at the end of the transmission line at 3, 4, and at 7, 8. To the right of the points 4 and 8 is the distributing network or the sub-station. The points 15, 16 are connected to test-wires, P P, and, by joining a galvanometer, g, to their ends, the leakage u and v (points 13 and 14) in the part of the network alone beyond the points 4, 8 can be observed. By connecting g simultaneously to 17, 18 and 15, 16 gives, on the other hand, the difference between the total leakage and that from the distributing network, and, consequently, the leakage x and y on the transmission line (points 9 and 10) The difference of potential between the wires P P is only a fraction of a volt, and their absolute potential lies half-way between the potentials of the main wires—two circumstances which are of value, as they render the test-wires harmless. This method can be extended to any number of sub-stations or distributing networks.

The apparatus (Fig. 9) employed for my tests was made by the European Weston Electrical Instrument Co., and I must not fail to express my thanks to the manager, Herr R O. Heinrich. Three main resistances W_+, W_0 and W_- are fixed on a common base, their resistances being each about 0·8 ohm and their dimensions such that they can carry a current of 25 amperes for a short time. They are fixed between the terminals 1, 4, 2, 5 and 3, 6 respectively. If the arms K of the switches are on the contacts 4, 5, 6, the current passes to the installation through the resistances W. The galvanometer g is connected to the ends of these resistances through other resistances e (not seen in Fig. 9 as they are within the base of the instrument), according to the arrangement in Fig. 7. If no measurement is being made, the arms K are placed on the contacts 7, 8 and 9, and the resistances W are short-circuited by the copper shunts n. In this case also the galvanometer remains connected across the house-terminals, but no deflection should take place as, owing to the resistances W carrying no current. To compensate any inequality in the resistances e, and in order to adjust the zero exactly, a small adjustable resistance wrie v is included in the galvanometer circuit. The galvanometer is a portable Weston needle instrument of about 250 ohms resistance and a sensibility of 1deg. = 0 0000025 ampere. The six resistances e (Fig. 7) are each about 900 ohms. Under these conditions a fault to earth of 10,000 ohms resistance or a leakage of 1,100 ampere (at a pressure of 105 volts on each side of the three-wire system) gave a deflection of 1deg. The instrument can, of course, be made more compact; the above is only an experimental form.

* A very similar system was described by Dr. V. Krempelhuber in the *Elektrotechnischer Anzeiger*, 1897, p. 730.

IMPROVEMENTS IN MAGNETIC SPACE TELEGRAPHY.†

BY DR. OLIVER LODGE, F.R.S.

(Continued from page 271.)

Induction *v.* Conduction.

As to the question between space induction and earth conduction, and the relative part each plays in any given case, it is a question which can be answered either by experiment or by calculation. In some cases experiment would be absurd, as, for instance, when either sending or receiving circuit is not earthed anywhere; in other cases, as at Lavernock, it can be answered either way. Now Mr. Gavey tells me that he has tried an experiment on this very point, by taking an insulated wire outstretched between two boats and "earthed" in the sea at either end. Signals being sent from the land, they could be heard out at sea to a certain distance when the wire was above water, but when it was immersed they disappeared at a smaller distance. The argument, of course, is that, regarded as the tapping electrodes of a conductive receiver, the ends of the wire acted similarly both times; but regarded as an inductive receiver responding to magnetic influences, the submerged wire was protected, be-

† Paper read at the Institution of Electrical Engineers, Dec. 8, 1898.

Digitized by Google

cause, let us say, the direct and return portions of the circuit, when the wire was immersed in the sea, were more or less coincident. And the moral is that induction contributed the greater part of the effect. It is not quite conclusive, however, because induction and conduction may aid each other anyhow, and, when either is stopped, the residual disturbance may be too faint to hear. A trial with a continuous current might, I think, conclusively measure the part due to conduction. So far as I know no attempt has been made to dispense with earth conduction altogether, by the use of a return wire along the beach; but calculation shows sufficiently that, if this were done, signalling would practically cease. It is a mistake to suppose that the negative result with the submerged wire depends on the reflection of electromagnetic waves at the surface of water, because true electromagnetic waves have in this installation nothing to do with the case. The water may and does to some extent act as a conducting screen, but it is sufficient to consider the immersion of the wire as resulting in simply closing up the receiving circuit until it is a long thin rectangle of inappreciable area, so that the direct and return circuits almost coincide. The experiment proves distinctly that induction has something to do with the result, and that it is not wholly due to earth tapping. Let us see if calculation bears this out.

Without presuming to quote exact details of an installation on which I am not authorised to report, I state only the facts obvious to inspection of the stations by boat. The distance between the earth-plates, or length of the base line, I take to be: At Lavernock, 1 mile; at Flat Holm, ⅓ mile. The average elevation of the line wire I take as 120ft. above the sea in each case; the elevated lengths as 1,200 and 460 yards respectively; and the distance between the stations as 3½ miles.

It may be noticed that in any case, even in this case where the line is straight, the bulk of the impedance is of the "reactance" kind, when a thick wire and high frequency are employed.* For, whereas the resistance might be something between 1 and 2 ohms, the value of pL is something more like 10 ohms if a note of 400 per second is employed; and in such a case the induced current is almost independent of the frequency, because $\frac{pMC}{pL}$ = constant as regards frequency. Hence, with a stronger primary current and lower frequency—say, 20 amperes alternating 20 times a second—the effect received would be decidedly stronger; whereas, if *resistance* had been the dominant feature, the effect of the stronger slower current would have been just the same as that of the smaller quicker one. It is chiefly for response at low frequency, I take it, that such thick copper wires have had to be employed; for, at low frequency, resistance does become the dominant feature.

Now, treating the sea first as if it were a superficial return circuit, or, rather, treating the case of a return wire along the beach, vertically below the line wire, the mutual induction co-efficient between two facing circuits of areas 40 × 1,200 square yards and 40 × 460 square yards respectively, at a distance of 3½ miles, is

$$M=\frac{2\times 4,800\times 18,400}{(6,160)^3}\text{yards},$$

or, say, 0 008 yard, or 0 73cm.

Accordingly, when a current of frequency 400 and 1 ampere mean strength is sent round either circuit, an E.M.F. is induced in the other of average value,

250 M C.G.S., or 1·8 micro-volts.

And I doubt if this could produce any appreciable effect; unless, indeed, the whole of the receiving circuit were attuned and arranged in the way to be presently described.

But a return circuit along the beach is not employed, and would evidently be very ineffective if it were. A return by the sea gives a more open area, and therefore an inductive advantage, in addition to any conductive contribution which it may furnish.

The other extreme case, decidedly more unfair in the opposite direction—so extreme that it is hardly worth consideration except as a warning not to reckon the mutual induction in this way—would be to treat the line wires as if isolated in space—bits of infinite parallel wires—the return current being at infinity. Taking this case for a moment, the mutual induction would be

$$M=\frac{1,200\times 460}{6,120}\text{ yards},$$

or about 80 metres, which must be far beyond the truth.

The actual return circuit depends on the distribution of conductivity in the earth, and is therefore indefinite. The fact that the resistance of the circuit varies with the height of the tide shows that the *sea* conveys most of the current.

Earth Conduction.

Now, calculating what share earth conduction ought to contribute in the matter, we may either treat the shallow sea as a conducting sheet fairly insulated in its bed, or we may postulate equal conductivity through the whole earth; the latter being certainly further from the truth than the former. Considering the electrodes as approximating in area to spheres of radius c, at a distance $2a$ apart, the applied difference of potential between them is

$$V=\frac{Q}{\pi k\delta}\log\frac{2a}{c};*$$

k being the conductivity, and δ the depth of the sea, supposed uniform and small, and Q being the quantity of electricity supplied per second.

The potential at any point distance r from one electrode and r' from the other is

$$U=\frac{Q}{2\pi k\delta}\log\frac{r'}{r};$$

so between two fairly neighbouring points situated symmetrically on either side of a point at a considerable distance r from either electrode,

$$dU=\frac{Q}{\pi k\delta}\cdot\frac{dr}{r}.$$

The distance between these tapping points being $2b$, we have

$$\frac{dr}{b}=\frac{a}{r};$$

therefore, the ratio of the tapped voltage to the total applied voltage is

$$\frac{dU}{V}=\frac{\frac{ab}{r^2}}{\log\frac{2a}{c}}.$$

Now, taking c as a metre, $2a$ as a mile, $2b$ as ¼ mile, and r as 3½ miles, we find that the tapped E.M.F. is a certain fraction of the difference of potential on the primary electrodes; the fraction being,

$$\frac{1}{\frac{3\times(3\frac{1}{2})^2}{\log 1,500}}=\frac{1}{37\times 2\cdot 3\times 3\cdot 18}=\frac{1}{270};$$

which represents a very considerable voltage. But this is the most favourable case, with the current limited to a sheet of sea only a few metres thick. An uncertain amount of current would be certainly lost by real earth conduction, and the other extreme case would be to take the whole earth as of uniform conductivity with sea water. This would give us very much too low a result, as the hypothesis of sea conduction alone has given us one too high. Considering the whole earth as conveying the current, half the tapped E.M.F. is

$$U=A\left(\frac{1}{r}-\frac{1}{r'}\right)=A\frac{dr}{r^2}=A\frac{ab}{r^3},$$

while the applied E.M.F. is

$$V=2A\left(\frac{1}{c}-\frac{1}{2a}\right)=\frac{2A}{c}\text{ approximately};$$

so the fraction $\frac{dU}{V}$ in this case is $\frac{abc}{r^3}$, a fraction so small as to give an imperceptible result.

Part II.—*Preliminary Experiments.*

I will relate briefly a selection from some of the early experiments made on simple wire circuits, at first often without condensers, in order to find what sort of value of mutual induction coefficient (M) was sufficient to give audible signals between a couple of coils of wire lying horizontally in the same plane.

1. Two coils of thin wire, each of 350 turns, and 30cm. (1ft.) diameter, with 5 amperes maintained in one at a frequency of about 100 by an alternating dynamo; a telephone connected to the other coil responded audibly when it was at 6 metres distance. The M in this case is 287 C.G.S., which is large, but no capacity was used to assist.

2. Two coils of No. 15 wire, each of eight turns, on a hoop 92cm. (1 yard) in diameter, and with 11 amperes maintained in one at a frequency of 120 by means of a make-and-break tuning-fork; a telephone in the other responded at 3½ metres. In this case the M=67 C.G.S.

3. A pair of coils in separate buildings 100 metres distant, each with a condenser, the transmitter being 60 turns of No. 18 wire

* I emphasise this because it has been doubted by the Post Office. A method for calculating the self-induction of a straight wire of length l and sectional radius c is given by Lodge and Howard in the *Phil. Mag.*, July, 1889, p. 64, and results in $L=2l\log\left(\frac{4l}{c}-\frac{3}{4}\right)$. Apply this to the Lavernock line wire: say $l=1$ mile, $c=\frac{1}{8}$in., we get L=4 millihenries; so for a note of 400 per second p L=10 ohms; and this is the practical impedance of the straight wire—its resistance being much smaller. It is a great mistake to suppose that in straight wires the self-induction is negligible.

* See, for instance, Foster and Lodge, *Phil. Mag.*, June, 1875, p. 453.

Digitized by Google

round a small room nearly four metres square, the receiver being one of the above hoops a yard across wound with eight turns of wire; the hum could be just heard. The M in this case is only 0·6 C.G.S., which is good.

4. The next experiment is worth quoting in fuller detail. It was made in 1897, a month or so later than the above called (1), when things had improved. Fig. 1 is a diagram of the connection at the sending end; the dynamo being replaced by a tuning-fork intermitter (all kinds of intermitters have been used in different experiments).

F is the Koenig fork on its massive stand, vibrating 111 complete swings a second.
b is a single storage cell, and M is the magnet and vibrating solid contact to maintain the fork's motion.
H is the mercury cup contact for the main current.
B is a battery of 16 storage cells.
S is a condenser of variable capacity, and C the coil of 60 turns approximately 4 metres square.
V is a voltmeter to indicate the potential difference at the terminals of the condenser.

The self-induction of the coil being calculated roughly as 0·06 henry, the appropriate capacity for tuning, to the fundamental and the different harmonies, would be :—

For the note 111 per second, S should be about 3·5 microfarads.
" " 222 " " " 8·6 "
" " 444 " " " 2·2 "

Practically it was found that 2·0 microfarads gave excellent tuning, sending up the voltmeter to 98 volts, though the applied E.M.F. was only 32 volts. And under these conditions the note of 440 could be distinctly heard in the small coil in the distant tower; and by introducing a key into the sending circuit, without interfering with the continual vibration of the fork, messages could be sent and read with ease. The receiving circuit was about 100 metres

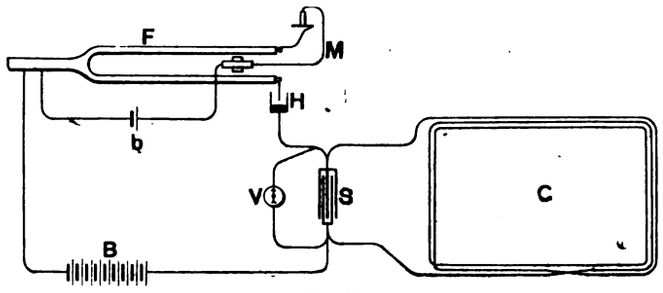

FIG. 1.

distant, high up in the College clock tower across the quadrangle, as in the last experiment; but the small hoop coil was replaced by a square coil of 22 turns of No. 18 wire about 3·8 metres square, whose L was, therefore, 0·008 secohm. A capacity of 16 microfarads was needed to attune the circuit to the note listened for.

5. Instead of any maintained alternator or intermitter of any kind, the make and break, or the reversals, of a signalling key were sometimes used alone to do the whole thing; and when a battery, such as 144 very small Planté cells, was employed, the induction ticks heard in the secondary at each charge and discharge of the primary condenser sufficed to give clear signals at a moderate distance, on the "sounder" plan, the beginning and end of each long and short signal being marked.

6. Another method is to have a much better insulated wire for the primary coil, and to discharge round it a Leyden jar with a short spark gap, excited by a Ruhamkorff coil; the spark being made whistling by a moderate glass-plate condenser (*see* "Modern Views of Electricity," Lecture III., p. 435, second edition), the shrill momentary sounds can be heard in a suitable distant telephone and coil.

7. A pair of coils nearly two miles distant were now arranged, the transmitter being a rough square 100 yards across with five turns of four No. 16 wires in parallel, and the receiver being a long rectangle of the same periphery, about 30 yards wide, consisting of 19 turns of No. 18 wire. A dynamo with a multiple armature was employed, which was coupled up so as to give a nominal voltage of 175 volts (240 as measured). Nothing could be heard at the distant station without condensers, although the M = 100 C.G.S. This was expected, because of the high impedance and resistance. But when condensers were added at both ends and adjusted for resonance to the first harmonic—about 200 per second—the tone became faintly audible. The transmitting condenser was 10 microfarads, viz., four 5-microfarad condensers, two in parallel and two in series, which, by resonance, ran the effective voltage up to 1,100 volts; and the receiving condenser was 2 microfarads, shunted by an ordinary 70-ohm Bell telephone.

The self-induction of the sending cable was in this case 0·02 secohm, to which has to be added 0·04 secohm for the dynamo; while the resistances were 4 ohms for cable and 1 ohm for dynamo. So the reactance part of the impedance for the octave frequency was nearly 80 ohms, and the current therefore only about 3 amperes without sending condenser. A condenser magnified it four or five fold. The sending condenser can always be replaced by a dynamo of higher voltage; but, on the other hand, given any dynamo, a sending condenser will increase its power, except on circuits whose resistance, and therefore damping, is excessive.

The self-induction of the receiving cable, as connected, was $\frac{1}{3}$ secohm approximately, and its resistance was 133 ohms. Even here, therefore, the impedance was more due to self-induction than to resistance, the value of pL being 410 ohms, and so the condenser was a great advantage. In fact, without it nothing could be heard, with the given amount of power expended.

It may be serviceable here to show how quickly to calculate the frequency for any given self-induction and capacity.

Let L be expressed in secohms or henries; let S be expressed in microfarads; then the resonance frequency of the circuit is

$$\frac{160}{\sqrt{(LS)}}.$$

So in the above case the syntonised sending frequency comes out,

$$\frac{160}{\sqrt{(0{\cdot}06\times 10)}}=208 \text{ per second};$$

the syntonised receiving frequency.

$$\frac{160}{\sqrt{(0{\cdot}32\times 2)}}=200;$$

and the fundamental note of the dynamo oscillated about 100.

The damping term of these particular cables, viz., $\frac{R}{L}$, is, however, certainly too high, and the wire used for such large circuits ought certainly to be thicker than No. 18 or 16. Coupling up the strands of wire in a telephone cable in different ways does not affect the damping constant, for the R and the L vary similarly; but the power of coupling them up differently is often convenient in enabling tuning to be got with a moderate condenser capacity, and, in general, in giving an adjustment for different notes. Otherwise, greater number of turns has just the same effect as thicker wire; it is simply *mass of copper* which is required to increase the power of a circuit to send or receive over big distances, and telegraphy over any distance by this method becomes, therefore, chiefly a matter of cost.

It may be well here to give the elementary theory of induction between a pair of circuits, each with condensers, especially for the case where the circuits are syntonised to the applied frequency. Consider a circuit with self-induction and resistance and capacity, driven by an alternator of E.M.F. $=E\cos pt$: the primary current in it is

$$C=\frac{E\cos(pt-a)}{\sqrt{\left\{R^2+p^2\left(L-\frac{1}{p^2S}\right)\right\}}},$$

where the lag a is given by

$$R\tan a=p\left(L-\frac{1}{p^2S}\right).$$

If there is exact tuning ($p^2SL=1$) the lag vanishes, and the current becomes

$$C=\frac{E\cos pt}{R},$$

its maximum value.

On a distant circuit with mutual coefficient M the induced E.M.F. is $\dot{MC}$, or, in the above case,

$$Mp\frac{E}{R}\sin pt;$$

so the induced current there is

$$x=\frac{Mp\frac{E}{R}\sin(pt-\epsilon)}{\sqrt{\left\{R'^2+p^2\left(L'-\frac{1}{p^2S'}\right)\right\}}};$$

which, if again there be tuning ($p^2S'L'=1$), becomes

$$x=\frac{MpE\sin pt}{RR'}. \quad \ldots\ldots\ldots \quad (3)$$

Let a cable contain $N=nm$ turns of wire, of resistance ρ_1 per unit length, coupled n in series and m in parallel, and be laid round a circuit of radius a: then

$$x=\frac{nn'\pi^2\frac{a^2b^2}{r^3}}{\frac{nn'}{mm'}2\pi a2\pi b\rho_1\rho_1'}pE\sin pt$$

$$=\frac{mm'}{4}\cdot\frac{p}{\rho_1'}\cdot\frac{ab}{r^2}\cdot\frac{E}{\rho_1 r}\sin pt$$

$$=\frac{ab}{4r^2}\cdot\frac{p}{R_1'}\cdot\frac{E\sin pt}{rR_1}, \quad \ldots\ldots\ldots \quad (4)$$

Digitized by Google

where R_1 is the resistance of unit length of the cable itself as connected.

Here the last factor in (4) is the maximum strength of current which the dynamo could send direct to the distant station if its cable were long enough to reach all the way, and if it were opened out as connected and laid straight, all the parallel turns parallel and all the series turns end to end; and with all the remaining self-induction impedance abolished by a suitable very large condenser.

The actual current received inductively is, therefore, a definite fraction of this direct line current: the fraction depending on the linear dimensions of each circuit compared with the distance, and on the frequency and on the effective thickness of the receiving cable.

Suppose we tried to signal a distance of 12,000 kilometres (across the earth) with a pair of No. 0 equal cables, each once round an area comparable to England, say a circle 200 kilometres in diameter, using a frequency of 1,000 and an applied voltage of 200; ignoring all hysteresis and other losses (which in condensers are often important), and ignoring also the conductivity of the earth, which may be very troublesome:

$$\frac{E}{R_1 r} = \frac{200}{0{\cdot}322 \times 12{,}000} = \frac{1}{20} \text{ ampere};$$

$$\frac{p}{R_1} = \frac{1{,}000 \times 2\pi}{3{,}220} = \frac{2\pi}{3};$$

$$\frac{ab}{4r^3} = \frac{100 \times 100}{4 \times (12{,}000)^2}$$

These are the three factors; so the induced telephone current is about 2 microamperes. which is within the limit of audition. The self-induction of such a cable would be between 2 and 3 secohms, its resistance about 200 ohms, and the capacity needed only about $\frac{1}{100}$ microfarad. This arithmetic is a mere illustration of what would happen if everything were favourable.

Consider further the arrangement of coils adapted to really distant syntonic magnetic space telegraphy with very precise tuning. The mutual induction coefficient depends upon $mm'a^2b^2/r^3$; or for imilar equal coils, each of periphery l and n turns,

$$Mr^3 = \text{the effect of the coil at a given distance} = n^2l^4.$$

The amplitude of disturbance maintained by an alternator of frequency p and voltage E_0, in a circuit whose natural frequency $p_0 = \frac{1}{\sqrt{(SL)}}$, may be written,

$$\frac{E_0/R}{\sqrt{\left\{1 + \frac{L}{SR^2}\left(\frac{p}{p_0} - \frac{p_0}{p}\right)^2\right\}}},$$

which in case of exact resonance becomes E_0/R. Hence, to make resonance *sharp*, the coefficient $\frac{L}{SR^2}$ must be great. If this condition is not satisfied there will be a considerable range of resonance within which some exaltation of voltage is felt, but no decided peak; whereas, if L/SR^2 is great compared with the period of one oscillation, then, except at a particular frequency, the circuit is nearly inactive, but as the correct frequency is approached the activity of the circuit suddenly runs up to a high steep maximum, and condensers are liable to be burst by the immense and rapid magnification of voltage.

Take the case of approximate resonance, so that $p^2SL = 1$ nearly, and introduced this value of S: then the coefficient which has to be big is $\frac{p^2L^2}{R^2}$; *i.e.*, for a given frequency simply the damping constant or logarithmic decrement, R/L, must be small, or the current-decay time constant, L/R, big, compared with the frequency time constant. Now

$$\frac{L}{R} = \frac{n^2l\left(\log\frac{3l}{c} - 2\right)}{\frac{nl}{c^2}} = nc^2 \text{ approximately}$$

where c is the thickness of the wire, which does not enter much into the numerator.

So the two things which we want big are n^2l^4 and nc^2; wherefore, in case of magnification of circuit for bigger distances, the thickness of the wire should be magnified as well as its length. Of course, for really high frequencies it is no use having a thick wire *solid*. It must either be ribbon-shaped, or be stranded, with the strands roughly insulated even if they are not going to be used otherwise than in parallel.

Magnification Ratio.

The amount of magnification of voltage caused by resonance is to be calculated thus:—The impressed E.M.F., or the E.M.F. of the sending dynamo, being E_0, the effective potential difference between the condenser terminals is such that, when there is syntony and when the damping is small,

$$\frac{V}{pL} = \frac{E_0}{R};$$

in other words, the magnification ratio is

$$\frac{V}{E_0} = \frac{pL}{R} = \tan a,$$

and approaches infinity as the lag of current behind E M F. approaches $\frac{1}{2}\pi$.

The primary current without a condenser would be $\frac{E_0}{\sqrt{(R^2+p^2L^2)}}$, but with the syntonising condenser it is $\frac{E_0 \tan a}{\sqrt{(R^2+p^2L^2)}}$, or, approximately, $\frac{E_0}{R}$.

But it is to be remembered that all hysteresis losses—whether they be due to an iron core in the coil, however subdivided, or by reason of a stratified or other imperfect dielectric in the condenser—and also all eddy-current losses by reason of induction in neighbouring conductors, whether insufficiently subdivided iron or earth or sea, all go to increase resistance—*i.e.*, to increase damping—and thereby to diminish the magnification ratio. If the R be measured in the usual way, by steady currents, it is liable to be supposed much smaller than it really is—*i.e.*, smaller than the really effective R for alternating currents—especially for high frequency. Part of the art of magnetic space telegraphy will consist in avoiding or minimising these various sources of loss, all of which show themselves as an increased resistance.

Perhaps the neatest way of proving that the magnification ratio equals pL/R is as follows:—Since in free oscillations $\frac{1}{2}SV^2 = \frac{1}{2}LC^2$, where V and C are the potential and current amplitudes respectively, and where $p^2LS = 1$, we get

$$C = V\sqrt{\frac{S}{L}} = \frac{V}{pL} = \frac{E_0}{\sqrt{(R^2+p^2L^2)}};$$

so the magnified or syntonic voltage, when the damping is small, is

$$V = \frac{pL}{R}E_0$$

To maintain these oscillations is the function of the dynamo, and for this purpose it has only to supply the waste power, viz.,

$$\tfrac{1}{2}RC^2.$$

Hence, in cases where R is large from any cause, considerable power is necessary; but where the R is small, including all the spurious losses which go to make up the effective R or dissipation constant, then violent oscillations can be maintained in a circuit with very little outside power.

The whole matter is analagous to the swinging of a heavy pendulum or bell whose motion is excited and maintained with little energy if the impulses are properly timed, but which requires more energy when swung in a viscous fluid. The time of applied impulses should be the same as if it were free, although the actual time of free swing is a little lengthened by the friction. For circuits oscillating with extreme rapidity one of the principal sources of spurious resistance, and therefore of damping, is radiation of waves, but with these leisurely circuits there is no radiation that need be taken into account in estimating the waste of power. A church bell stiffly hung would become but little easier to swing if its clapper were removed and its wave-emitting property destroyed.

Best Condition for Distant Sending.

Having realised that any distance can be reached if enough copper and enough power are employed, it remains to reckon what is the best way of arranging the copper, and how little will serve to enable a given power to signal a given distance. When nothing else has to be considered, the condition to be satisfied for signalling to a great distance is to make the magnetic moment of either coil as great as possible; its value is $n\pi a^2\mu C = \frac{\mu\kappa WE}{4\pi n}$ when syntonised; so all the copper available, W, should be disposed in one large single circuit at each station.

Possibility of Using Iron.

If iron is used as the core of a sending coil, it should be minutely subdivided, and should, if possible, be hot—as near its critical point as practicable—because then both hysteresis and eddy losses are at their minimum: see a most interesting communication on the behaviour of iron at different temperatures by Mr. D. K. Morris in *Proc. Phys. Soc.* for 1896-97.* A transmitter, shaped like a chimney or a lighthouse, with a long vertical thin iron strip core surrounded by many turns of wire, would be most efficient if only the damping losses could be got rid of. For the function of the sender is to produce the strongest possible alternating magnetic field at a distance, and this depends simply on magnetic moment, being $\frac{m}{r^3}$ at any distance r in an equatorial plane; and this field, though excessively and imperceptibly weak at any point, is then to be detected by the integrating power of the receiving coil over

* Abstract in *The Electrician*, Vol. XXXIX, p. 143.—[Ed. *E.*]

Digitized by Google

a large area. So, in general, if a magnet of moment m oscillates $2\pi p$ times a second, and the receiving circuit is of area A, the number of lines passing through that circuit is Am/r^3, and p times this is the maximum induced E.M.F. which a telephone or other instrument in the receiving circuit has to detect if it can.

Best Size and Shape of Coil for Violent Resonance.

It is of interest to find the shape of coil adapted to reduce damping due to ordinary resistance to a minimum. Let the coil be of mean radius a, of sectional radius c, and consist of n turns: then the volume of copper in it, ignoring insulation, is

$$W=\frac{\pi^2 c^2}{4n}\times 2\pi na=\tfrac{1}{2}\pi^3 ac^2;$$

$$L=4\pi n^2 a\left(\log\frac{8a}{c}-1{\cdot}75\right);$$

$$R=\frac{2\pi na}{\pi^2c^2}=\frac{8n^2a}{\pi c^2\kappa}=\frac{(2\pi na)^2}{\kappa W}.$$

The damping time-constant, or reciprocal of the logarithmic decrement, is

$$T=\frac{L}{R}=\tfrac{1}{2}\pi^2\kappa c^2\left(\log\frac{16W}{\pi^3c^3}-1{\cdot}75\right)=\frac{\kappa W}{\pi a}\left(\log\frac{8a}{c}-1{\cdot}75\right).$$

So T will be a maximum, and the damping a minimum for

$$\frac{dT}{dc}=2c\left(\log\frac{16W}{\pi^3c^3}-1{\cdot}75\right)-3c=0;$$

or $$\log\frac{8a}{c}=1{\cdot}75+1{\cdot}5=3{\cdot}25;$$

or $$\frac{a}{c}=3{\cdot}22;$$

which is, therefore, the condition for maximum T with a given W—*i.e.*, the condition for least damping, with a given bulk of copper.

This maximum $T=T_m=\frac{3}{4}\pi^2\kappa c^2=\frac{3\kappa W}{2\pi a}=\frac{3\kappa}{5{\cdot}5}W^{\frac{1}{3}}$

(=3·4 seconds for a ton of copper).

The E.M.F. which the condenser will have to stand is pTE_0.

The L appropriate to T_m is

$$L_m=6\pi n^2 a=16{\cdot}5n^2W^{\frac{1}{3}}$$

(=1,650n^2 for a ton of copper).

The mean periphery of the coil is $5{\cdot}5W^{\frac{1}{3}}$

(or 5½ metres for a ton of copper).

The thickness of the coil, $2c=\frac{4W^{\frac{1}{3}}}{2{\cdot}345\pi}$

(=53 centimetres for a ton).

Such a thickness of coil may seem preposterous, but in certain confined spaces (*e.g.*, a lighthouse) it is advantageous so to be able to dispose the circuit, and the coil may consist of any amount of turns without detriment. What has to be scrupulously avoided in the neighbourhood of any coil is conducting material; but the reaction effect of such material falls off rapidly with distance—as the inverse 6th power (*see* Lodge, *Phil. Mag.*, Feb., 1880, p. 142)—and accordingly it is to be hoped that the general conductivity of the earth will not exert a very deleterious effect. Its effect will certainly be in the direction of increasing the resistance, and therefore the damping, of either coil; but, beside this reaction effect, a true partial screening of one coil from the other is to be found.

The thickness of wire is

$$c\sqrt{\frac{\pi}{n}}=\frac{W^{\frac{1}{3}}}{2{\cdot}07\sqrt{n}}\left(=\frac{50}{\sqrt{n}}\text{ for a ton of copper}\right).$$

Thus, for instance, the coil might have 10,000 turns of wire half a centimetre thick (No. 5½); the outside diameter of the coil would be 2½ metres, and the inside diameter 1¼ metres. Such a coil would weigh a ton, and its resistance would be

$$R=\frac{48{,}000\,n^2}{W^{\frac{1}{3}}}=480n^2\text{ C.G.S.}=48\text{ ohms}$$

Its self-induction would be 165 henries; its time of falling to $\frac{1}{e}$ the current, 3·4 seconds; and its magnification ratio, with a note of 400 per second, would be 8,500. The condenser to be used with it for this note would be about $\frac{1}{10{,}000}$ microfarad, or 9 metres electrostatic capacity. It might have an air or fluid dielectric to lessen hysteresis, and must be able to stand a very high potential—for instance, nearly a million volts if the applied dynamo E.M.F. is 100 volts. The current in the wire would be only 2 amperes, and the energy expended therefore insignificant, viz., about 200 watts. In such a case the signalling would be done by the agency of the mass of copper rather than by mechanical power, and the tuning would be excessively sharp. There may be a few places where it is desirable to economise power to this extent, as, for instance, when the dynamo has to be driven by hand, or where space is very cramped, as in a lighthouse; but in most cases it would be far better to expend more power and open out the coil into a circuit enclosing a large area. This could nearly always be done at *one* of the stations.

A compact coil like this is not a powerful sender or receiver, in spite of its high magnification ratio. For instance, using a pair of such coils, one as sender and one as receiver,

$$Mr^3=(\pi na^2)^2=\tfrac{1}{4}\kappa RWa^2=\frac{10^{18}}{18}\text{C.G.S.}$$

So the induced current, when properly attuned, is

$$\frac{pEM}{R^3}=2{,}500\cdot\frac{100}{48}\cdot\frac{10^{18}}{18r^3\times48\times10^9}=\frac{6{\cdot}4\times10^9}{r^8}\text{C.G.S.}$$

So the distance at which this current would be a microampere (10^{-7} C.G.S.), or something quite audible, would be

$$r=\sqrt[8]{64\times10^{16}}=4\text{ kilometres only.}$$

Throttling.

The thickness of wire permissible without insulated subdivision into strands is regulated by the frequency. Taking Lord Rayleigh's value of the initial throttling, $p^2L^2\mu^2/12R^2$, it comes out $1{\cdot}2n^2a^4\times10^{-5}$ C.G.S. for copper; so, if the throttling is not to result in a greater increase of resistance than 1 per cent., a thickness of wire 1·08cm., or No. 5/0, may be used for a frequency of 100 per second.

For 500 per second nothing thicker than 0·48cm., or No. 6, should be used without subdivision.

For 1,000 per second No. 10, or 0·34cm. thickness, is permissible.

For 1,600, No. 12; and for 2,500 per second the appropriate thickness is 0·216cm., or No. 14 S.W.G.

If No. 2 wire, or 19/16, is used for 500 per second frequency, the loss due to throttling is 5 per cent.

If No. 0, or 19/12, is used, the loss is 9 per cent.

But if the strands are each cotton-covered before stranding, then there is practically no loss.

(To be concluded.)

LUMINOUS SIGNAL TELEPHONE SWITCHBOARDS.*

BY KEMPSTER B. MILLER.

The advantages of incandescent lamps over the electro-mechanical signal are many, and among them may be mentioned the following: First, they are capable of attracting the attention of an operator with much more certainty than the ordinary mechanical shutter; second, they are entirely free from mechanical complication, and, therefore, unlikely to get out of order or to fail in action, unless entirely destroyed; third, they are much more compact than even the simplest electro-mechanical signals; fourth, they are entirely automatic in their operation, being always restored to their normal condition by a cessation of the current through them; fifth, by the use of various coloured glass in front of them they may be used in the same board as indicating separate kinds of information; sixth, they are easily replaced when destroyed; and, seventh, they are as cheap, if not cheaper, than the high-grade tubular drops now in such common use.

Obviously there are two different methods of associating incandescent lamps with the circuits of the subscribers' lines. The first of these, and without mature consideration the most desirable, is to place the lamp directly in the circuit of the subscriber's line, and operate it automatically by a change in resistance in the line, brought about by the removal of the subscriber's receiver from the hook. The second is to have the lamp in a local circuit controlled by a relay directly in the line circuit, which relay may be operated by an ordinary subscriber's magneto-generator or by a source of current at the central office thrown into action by a change of resistance at the subscriber's station.

In the former method we find ourselves confronted with several rather serious objections; in the first place, the resistances of no two subscribers' circuits are the same, owing to the differences in the lengths of these circuits and other causes, and, therefore, either the inductive resistances at the exchange end of the circuit or the resistance of the subscribers' bell magnets will have to be varied in each case in order to ensure the proper amount of current passing through the lamp. This is a feature easy to overcome, and a much more serious one is that arising from crosses between two line wires from any source whatever, such a cross, of course, always subjecting the lamp to an undue amount of current, and, therefore, burning it out. This latter objection has proved so serious as to cause the abandonment of the plan of including the lamp directly in the line circuit in nearly every case where it has been tried. Of course, for underground systems this objection is not such a serious one.

Passing now to the second method of associating the lamp signal with the line circuit, reference will be made to Fig. 1. This shows the circuits of three subscribers' stations, S, S^1 and S^2, these

* Abstract from the *American Electrician*.

Digitized by Google

circuits being connected with the central office by the metallic circuits 1, 2. The line wire 1 in each case passes to the sleeve spring d^2 of the spring-jack J, and thence through the relay contacts c^1 to the ground. The line wire 2 passes in a similar manner to the tip spring d, thence through the relay contacts c^2, the winding of the relay b, and the battery a to the ground. The signal lamp e is in each case included in a local circuit, containing a battery f, common to all lamps, and the contact 4 of the relay b belonging to its line. The relay c of each line, which controls the contacts c^1 and c^2 is known as the cut-off relay, and is included in a local circuit through the jack thimble d^1, and the plug contact m, with the battery n, whenever a plug l is inserted into a jack for making connection with the line. The two sides of the line at the subscriber's station are permanently closed through a high-resistance bell B and a condenser C, the latter being of considerable capacity, so as to allow the alternating currents from the calling generator at the central office to pass through it and operate the call-bell in the usual manner. The high impedance of the call-bell magnets, however, prevents the short-circuiting of the voice currents when the receiver is removed from its hook. The call-bell circuit, therefore, presents an open circuit to the direct current from the battery a, thus normally insuring a condition of no current upon the line wire. When, however, the receiver at the subscriber's station is removed from its hook, a path of comparatively low resistance is formed

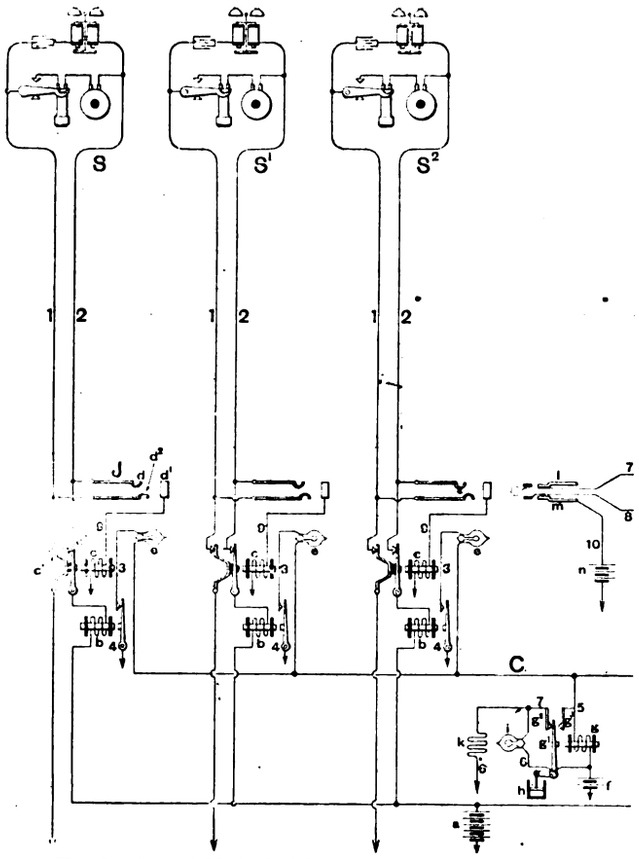

FIG. 1.—Second Method of Luminous Signal Connections.

between the two low line wires, and a current proceeds from the battery a, through the relay b, contact c^2, line wire 2, to the subscriber's station, back by line wire 1, through relay contact c^1, and by ground to the opposite terminal of the battery a. This current is sufficient to operate the relay b, and unlike the case where the lamp was used directly in the line wire, a considerable variation in the amount of this current is allowable. The operation of the relay b closes the circuit of the lamp e through the following path :—From the battery f, through the relay g, wire 5, common wire C, lamp c, wire 3, relay armature 4, and back by ground to the opposite pole of battery f. For the purpose of clearness, the relay g need not be considered at all at present, as it has nothing to do with the operation of the lamp e, and we may, therefore, consider one pole of the battery f to be connected directly to the common wire C. The closure of this circuit illuminates the lamp e. The next step in the operation of the system is the insertion of the plug l into the jack of the line on which the signal is displayed. The insertion of this plug closes the circuit through the relay c over the following path :—From the battery n, wire 10, plug sleeve m, thimble d^1, wire 9, relay coil c, to ground and back to the opposite pole of the battery n. This causes the relay to attract its armature and break both of the contacts c^1 and c^2, thus accomplishing a double purpose, the first of which is to break the circuit through the relay b, and thus cause it to release its armature 4, breaking the circuit through the lamp e ; and the second of which is to cut off both sides of the line circuit 1, 2, beyond the spring-jack J. This latter feature is a very important one, since it removes all difficulty from cross talk and other troubles in the auxiliary circuits of the central office.

The circuits illustrated in Fig. 1 are substantially those in common use by the Bell Company in their lamp signal exchanges, so far as the circuits of the relays and lamps are concerned. Several different modifications of the circuits at the subscribers' stations have, however, been used. The subscribers' stations may or may not include local batteries, and the tendency of practice is now to do away with these entirely and to supply current from central office for the operation of the transmitters as well as for all signalling purposes.

The relay g and its associated apparatuses form a very interesting addition to the system as outlined. It is found desirable to use what are termed pilot lamps for certain groups of line lamps, for the purpose of attracting the operator's attention more surely to a signal on her board. If two or more signals are displayed at once but one of them may attract the attention of the operator, who might, therefore, neglect the other. Pilot lamps are used in such connection that they remain lighted as long as any one of the line lamps in their group are lighted, and as they occupy a very conspicuous position and are as a rule brighter than the others, they cannot escape the operator's attention. Obviously it would be a serious objection to put a relay for operating such a pilot lamp in the common wire C of the local circuits of the lamps e, for the reason that the fall of potential or drop through such a relay would vary, according to the amount of current passing through it, and if several of the lamps e were operating at the same time they would probably not, therefore, receive enough current to properly illuminate them. The relay g is, therefore, included in circuit with battery f, and means are provided whereby its resistance will be short-circuited the instant it is operated. To accomplish this, the armature g^1 makes contact with the point g^3, as soon as it is attracted, thus short-circuiting the resistance of the coil g. At the same time it breaks contact with the point g^2, and

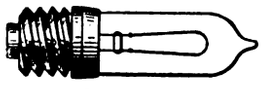

FIG. 2.—Signal Lamp.

thus allows the current to flow from the battery f, through the lamp i and resistance k, thus illuminating the lamp. In order that the armature g may not fall back against the contact point g^2, as soon as the coil d is de-energised by being short circuited, a small dash pot h is provided in connection with the armature to render its movements sluggish. Thus before the armature g^1 has time to move very far away from the point g^3, owing to its sluggish action, it will be at once attracted again, and the interval during which the resistance coil g is in circuit with the common wire C and the lamps e is so small that it does not have time to affect these lamps. This system is due to Mr. C. E. Scribner.

The incandescent lamps commonly used for signalling purposes and telephone work are of the type shown in Fig. 2 ; the lamp is about $\frac{3}{8}$in. in diameter, and $1\frac{1}{4}$in. long over all. They are commonly built for 10 or 20 volts pressure, the tendency being rather to increase the voltage than to decrease it. At first lamps of two and four volts were used, but for various reasons, not the least among which was the trouble of securing proper contacts at the relay and switch points for such low voltages, the voltage was gradually increased to the above-mentioned figures. Mr. A. H. Abbot, of Chicago, has recently given some interesting figures concerning the life of incandescent lamps in switchboard work, and mentions one case where a lamp was flashed over a million times without showing serious signs of deterioration. His tests seem to indicate that for general service in switchboard work the average lamp will live for a period of about 1,200 hours, although in laboratory tests a much longer life has proved possible. He points out, as a result of his observations, that, according to theory, the lamps used in subscribers' line circuits should last about 25 years, and those in the cord circuits used as "supervisory" and clearing-out lamps, for from one to two years. He also says that such a life has already been obtained in the cord circuit lamps, but that it is doubtful if the theoretical limit for the line lamps will ever be closely approximated.

LEGAL INTELLIGENCE.

Employers' Liability.

In the City of London Court, on Monday, Mr. G. Pitt-Lewis, Q.C., heard an action brought under the Employers' Liability Act by Charles H. Wild, 16, Seckford-street, Clerkenwell, London, to recover £50 damages for personal injuries sustained while in the service of the defendants, the County of London and Brush Provincial Electric Lighting Co. (Limited).

In opening the case, Mr. THOMPSON, for plaintiff, said that the claim arose from a set of circumstances quite out of the common. Plaintiff was in the employ of defendants, and on July 22 last, after having been working at the mains in various capacities for three or four years, he was ordered by defendants' foreman, Strahan, to go into a transformer box in St. John-street-road, Clerkenwell, and there to put a new fuse into a high-tension switch. While engaged at this work an explosion suddenly occurred. Plaintiff was very severely injured on the left arm and hand, and was unable to follow his occupation for some time. The transformer box was about 9ft. deep and 7ft. 6in. square. Plaintiff was a labouring man, and no doubt ought not to have been put to do the work at which he was engaged when the accident happened.

Defendants asserted that plaintiff was an inspector, and not a labourer.

The DEPUTY-JUDGE suggested that he would probably be called a ganger."

Mr. THOMPSON said his client was not a skilled electrician, and the work was dangerous. The defendant company drew up a series of rules, the first of which required the plaintiff to wear rubber gloves (which they had provided), when he was engaged near the high-tension mains, because of the danger. The work in question was the first the defendants had ordered the plaintiff to do of so dangerous a nature. It was really fitter's work, and should not have been entrusted to him. The fact was, the high tension mains should have been disconnected at the head offices, or head-quarters, before plaintiff did the particular work which brought about the accident. He thought the high tension mains were disconnected, instead of which they were not. The accident was brought about by an explosion, not a shock. The explosion was heard 40 or 50 yards off, and had nothing to do with the wearing of the gloves as had been suggested.

Mr. BELL (for defendants) said he would show that the whole accident had been caused through the plaintiff not wearing the rubber gloves. He had broken the rule requiring him to wear them, and he must put up with the consequences. It was idle to suggest that electricity could cause an explosion.

The DEPUTY-JUDGE: It was a sort of young thunderstorm?

Mr. THOMPSON agreed. If the electricity had been switched off, there would have been no explosion.

The PLAINTIFF said he ought not to have been put to supply a new fuse pot. The weather was very hot at the time, and his hand was very hot indeed. To enable him to do his work better, he took one of his rubber gloves off. The explosion was a terrible one. "The room filled with electricity, and at first he thought the place was blown away." He reported himself to the office, but the superintendent told him his injuries were nothing, and for the day he was to keep on at work. For ten weeks he was unable to follow his occupation. His hand was in dreadful agony at the time, and he went to St. Bartholomew's Hospital, where he was treated. He denied that he used a screw-driver improperly, and formed an arc which brought about the explosion. If he did form an arc, he certainly did not know it. He had had no experience with electricity. It was true he had been with the defendants for some years, but he had never had any technical instruction.

JAMES WILD, who had had, he said, long experience in electrical matters, gave it as his opinion that the plaintiff ought not to have been put to do the work allotted to him. Just as the plaintiff would not be allowed to go into a generating station, so no one but a fitter should have done the plaintiff's task.

The DEPUTY JUDGE supposed the plaintiff was being promoted, and was generally bettering himself.

Mr. BELL said no responsibility could attach to the defendants for the accident which had happened. They provided the plaintiff with a pair of rubber gloves, which would have completely insulated him from any danger, but he left them off. He must have formed an arc with the screw-driver or the explosion could not have occurred.

Mr. CHILD, assistant engineer to the defendant company, said it was the plaintiff's duty to do any small things, such as the job at which he was engaged when the accident happened. The plaintiff was altering one of the "sneezers," and it was not customary then to turn off the current. It could be done, but it was not the practice. The electricity did not go through the sneezer in any way. If a man was ordinarily careful and wore his gloves there was no danger about the work. The gloves were a perfect protection. The terminal was about 1½in. from the sneezer. The plaintiff's first duty was to go into the boxes and see that all the fittings were in order and that no fuses had gone. If any had gone his duty was to replace them. He could not class plaintiff as a labourer, although he only received 29s. 6d. per week.

STRAHAN, defendants' foreman, said that if the plaintiff had 2,000 volts to contend with, and he was wearing his gloves, no acccident would have befallen him, even if flame came out.

The DEPUTY-JUDGE, in giving judgment, said no doubt the plaintiff did not know much about electricity, but everybody must have a beginning, and no doubt he was an improver. There were certain risks which had to be borne by everyone. He did not think the plaintiff was sufficiently cautioned about the dangers which were around him. No doubt very proper instructions were given him, but only in a general way. The plaintiff might think himself very lucky that worse injuries did not befall him, for it had been shown in the evidence that if he had been a little taller he would in all probability have been killed. The injuries were serious, and, at the same time, he would like to say that he did not think the defendants' men were to blame. Nevertheless he must hold that it was one of those accidental circumstances which would happen, and that as the plaintiff was not sufficiently cautioned, there must be judgment in his favour for £15. He wished to add that the accident was one which no one could be expected to have foreseen as it occurred through a combination of circumstances.

Illegality of Picketing.

At the end of November last an action was tried in the Court of Appeal before the Master of the Rolls and Lords Justices Chitty and Vaughan Williams, viz., "Lyons and Sons *v.* Wilkins and Others," and was an appeal of the defendants from an order made by Mr. Justice Byrne in February last, restraining defendants by perpetual injunction from watching or besetting plaintiff's premises with the object of preventing persons from working for the plaintiffs or for any other purpose than that of obtaining or communicating information. The plaintiffs are the owners of a large manufacturing business in London in the leather trade, and the defendants are the secretary, chairman, and trustees of the Amalgamated Trade Society of Fancy Leather Workers. The proceedings arose out of a strike of plaintiffs' workpeople in January, 1896. It was admitted in the action that there had been picketing and peaceful persuasion by defendants. The original action was brought under Sec. 7 of the Conspiracy and Protection of Property Act of 1875. This section reads:—

"Every person who, with a view to compel any other person to abstain from doing or to do any act which such other person has a legal right to do or abstain from doing, wrongfully and without legal authority" (*inter alia*). "(4.) watches or besets the house or other place where such other person resides, or works, or carries on business, or happens to be, or the approach to such house or place, shall, on conviction thereof by a court of summary jurisdiction, or on indictment as hereinafter mentioned, be liable either to pay a penalty not exceeding twenty pounds, or to be imprisoned for a term not exceeding three months, with or without hard labour. Attending at or near the house or place where a person resides, or works, or carries on business, or happens to be, or the approach to such house or place, in order merely to obtain or communicate information, shall not be deemed a watching or besetting within the meaning of this section."

After hearing evidence, judgment was deferred and was given on Monday.

The MASTER OF THE ROLLS said: The construction put by this Court on the act of 1875 when the case was heard in March, 1896, is adverse to the present appellants, and was, in my judgment, correct. Upon the present appeal, however, one or two important questions were raised which do not appear to have been considered on the former occasion, and to them I now confine myself. The great point made by the appellants' counsel turned on the word "wrongfully" in sec. 7. He contended that to "watch and beset" another person's house was only illegal if done—(*a*) with a view to compel him to abstain from doing or to do some act which he has a right to do or not to do; (*b*) wrongfully and without legal authority. He further contended that nothing could be said to be wrongful which did not violate some right of complainant, and that there was nothing wrongful in watching or besetting a house simply in order peacefully to persuade others to conduct themselves in some particular way which was not unlawful for them to follow. This argument is, in my opinion, based on a misconstruction of the section, which is a penal section, as is shown by the sub-heads 1, 2, 3 and 5 of the section to which those words are as applicable as they are to sub-head 4. If the overt acts mentioned in sub-head 1, for example, in using violence or intimidation are proved, and it is proved that they were done with a view to compel, &c., and there is no reasonable ground for justifying them, it is unnecessary to give further evidence to prove that they were committed "wrongfully and without legal authority." The truth is that to watch or beset a man's house with a view to compel him to do or not to do what it is lawful for him not to do or to do is wrongful and without lawful authority unless some reasonable justification for it is consistent with the evidence. Such conduct seriously interferes with the ordinary comfort of human existence and ordinary enjoyment of the house beset, and such conduct would support an action on the case for a nuisance at common law. Proof that the nuisance was "peaceably to persuade other people" would afford no defence to such an action, Persons may be peaceably persuaded provided the method employed to persuade is not a nuisance to other people. Another point made by appellants' counsel was that what was done in this case gave the plaintiffs no cause of action. It is said that to beset one person's house with a view to compel some one else is not within the section. Such a construction would render the Act nugatory in a great number of cases clearly within the mischief intended to be remedied. In the present matter, the whole object of what was done was to compel the plaintiffs to comply with Mr. Wilkins's (the secretary) terms, and although there was no violence or overt threat of violence, it is quite plain that the relays of men set to watch and beset the plaintiffs' house (and the house of a man named Schönthal, who worked for him) were sent to do, and that they did, a great deal more than "attend" where they were "in order merely to obtain or communicate information." It is all very well to talk about peaceable persuasion and to draw fine lines between persuading and giving information. In this case there is no difficulty whatever in coming to the conclusion that what was done was watching and besetting as distinguished from attending "in order merely to obtain or communicate information." That the provisions of the Act were infringed appears to me to be plain and beyond all reasonable doubt. This appeal must therefore be dismissed, with costs.

Lord Justice CHITTY said: Mr. Justice Byrne, when trying the action, found that it was clearly proved that the appellants watched and beset the plaintiff's works or place of business and the approaches thereto for the purpose of persuading or otherwise preventing persons from working for the plaintiffs, and for purposes other than that of merely obtaining or communicating information. This finding of facts is accepted by

Digitized by Google

counsel on both sides. It was admitted by plaintiffs' counsel that the pickets (as they are called) used no violence or intimidation or threats. The picketing extended over some months, covered all the working hours of the day, and was conducted by relays of men in succession. The object in view was clearly shown by the white cards distributed by the pickets and the other documents referred to. The picketing and the acts done by the pickets were done with a view to compel the plaintiffs to abstain from doing or to do acts which the plaintiffs had a legal right to do or abstain from doing, viz., to compel them to change the mode of conducting their own business. To avoid any possible misapprehension, I state that the strike itself was lawful. The question on the appeal, in my opinion, turns on the 7th section of the act of 1875, and the construction and effect of that section were dealt with by this Court on the motion, and the decision then arrived at is binding upon us, subject, of course, to the point whether it can be shown to be erroneous as being in conflict with previous rulings, and I cannot find that it is. The acts of watching and besetting proved in the present matter were acts in themselves unlawful at common law and are not made lawful by the Legislature. In my opinion they constitute a nuisance at common law. It is true that every annoyance is not a nuisance; the annoyance must be of a serious character and of such a degree as to interfere with the ordinary comforts of life. To watch or beset a man's house for the length of time and in the manner and with the view proved would undoubtedly constitute a nuisance of an aggravated character. It must be borne in mind that the 7th section referred to, although it probably arose out of trade disputes, is not confined to trade disputes or to disputes between masters and men. It applies equally to all Her Majesty's subjects of every class. It would embrace the case of besetting a man's house with a view to compel him not to receive guests or visitors. Lord Herschell, in a House of Lords appeal "Allen v. Flood," said: It must now be considered clear law that a person who "wrongfully and maliciously or, which is the same thing, with notice, interrupts the relation subsisting between master and servant commits a wrongful act." It had been urged, in regard to the picketing of the workman Schöntal's residence, that besetting the house of one person with a view to compel another is not within the section. I think it is. Besetting a workman to compel a master and besetting a master to compel a workman are both plaints within the mischief aimed at. Schöntal was an outworker for the plaintiffs. The result is that the appellants have failed.

Lord Justice VAUGHAN WILLIAMS concurred.

The appeal was dismissed with costs.

Mr. Sam Woods, M.P., secretary to the Parliamentary Committee of the Trades' Union Congress, has issued a manifesto to the officers and members of trade unions on the subject of picketing. With the object of securing a decision in the courts more favourable to trade unionists on the question of picketing an appeal for funds is made. It is said to be the intention of the trade unionists to take the appeal "Lyons and Sons *v.* Wilkins and Others" to the House of Lords.

Gold v. Winter.

At Westminster (London) C.C. last week an action "Gold v. Winter" was heard.

Mr. C. P. ROSE-INNES, counsel for plaintiff, said the claim was for £75, the balance of £100 commission due to the plaintiff. In 1891 the Chiswick local authorities obtained a provisional order and Messrs. Bourne and Grant had obtained an option under that order. Nothing much had been done, and the Chiswick Council was afraid they would lose the order. His client came upon the scene, and defendant arranged to pay him a salary and £100 as commission upon each provisional order he was instrumental in introducing to him and which he obtained the option of. He went to many places and among them Chiswick. He there saw Mr. Trentham. By the introduction thus brought about, the provisional order was obtained by defendant from Bourne and Grant. All his client had received was £25.

Mr. H. S. GOLD said the interview took place at defendant's office in Norfolk-street, Strand, in the presence of Mr Presland. In consequence of the arrangement referred to he went to Chiswick to see Mr. Trentham, and afterwards placed Mr. Trentham in communication with defendant, and told defendant that, through Mr. Trentham, he would be able to get this business. Defendant subsequently got the option of the order and sold it to Mr. Brooke-Hitching, and for that defendant got £1,000 in cash, and if a company was formed within six months he would get a further £1,000 in shares; if not, he would have the cash. He believed defendant had had the whole £2,000. Defendant discharged him after paying him £25 because he had stood up for Mr. Trentham, who had only come into the business on condition that he was to be the consulting engineer in the matter.

Judge LUMLEY SMITH: Has Chiswick got the electric light yet?

Mr. ROSE-INNES: They are playing with the option. It has been resold for £5,000.

WITNESS: Mr. Presland was an engineer, and was present at the conversation when the arrangement was made at the defendant's office. Defendant promised him a salary of £3 a week and all disbursements, and £100. He entered into an engagement with Messrs. Sax and Co., and there was an action, which was settled. He had been secretary of the Lambeth Ratepayers' Association for three years, which body was opposed to a monopoly, and wanted the parish to have the control of the lighting itself. It was absolutely untrue that he used his position as secretary of the Lambeth Association to further the interests of Messrs. Sax and Co. Mr. Winter was connected with Lambeth. He introduced Mr. Trentham to Mr. Winter, and Mr. Trentham brought the matter through by introducing Mr. Winter to Bourne and Grant. Defendant paid him his salary all through.

Mr. W. H. TRENTHAM said plaintiff called upon him, and eventually he was introduced to defendant., and he introduced defendant to Mr. Marks, of Bourne and Grant's, and he was to be appointed consulting engineer to the new company. He was not, so he brought an action against defendant and Mr. Brooke-Hitching, which was settled without going into Court. He knew the engineer at Bourne and Grant's, and he introduced defendant to Mr. Marks in December last or January of this year. He knew those gentlemen were not acquainted with one another. He had previously made Mr. Marks' acquaintance. He introduced the business through Mr. Gold. He had never paid Gold anything on account of Chiswick. Plaintiff was in his employ in July at a salary.

Mr. ROSE-INNES called Mr. Brooke-Hitching, who did not appear, and a solicitor on his behalf said there was no need, as he produced the agreement. Mr. Brooke-Hitching did not know so much about it as he (the speaker) and it was only done with another object, viz., to bring pressure to settle the action. He produced the agreement.

Mr. G. CROYDON MARKS said in 1896 he was acting for Mr. Bourne, who was the largest shareholder in Bourne and Grant (Limited), and he had instructions to sell the option owing to the death of Mr. Grant. This was advertised, and he received several replies, but the purchase was not carried out until 1897. He first saw defendant in December 1897, and at that time he had not seen Mr. Trentham or heard of him. Defendant came alone to see him, and he said, in answer to witness's questions, that the matter had been brought under his notice. This was not a sale of the option, but of the shares of Mr. Bourne in the company. A few days after he called again with Mr. Trentham. The sale took place to Mr. Winter. Those who bought the shares really bought the option. The option would have expired in two months from the date of the sale. His company got the option in 1893. Winter sold it to Mr. Brooke-Hitching. The Bourne and Grant Company had provisional orders at Aberystwith and Chiswick. Instead of Mr. Trentham bringing Winter, it was the other way about.

The further hearing was adjourned for the attendance of witnesses.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

NEW BOOKS AND EDITIONS.

The following New Books and Editions can be obtained of the Booksellers or direct from the Publishing Offices, 1, 2 and 3, Salisbury court, Fleet-street, London:—

NOW READY.

"Electrical Testing for Telegraph Engineers."—By J. Elton Young, M.I.E.E. The scope of the book aims at furnishing a fuller treatment of the subject, from the standpoint of the Telegraph Engineer, than it has hitherto received, whilst it endeavours to facilitate a thorough comprehension of the theory of testing as applied to electrical lines in general. The Author hopes that, besides Telegraph and Telephone Engineers, it may, perhaps, also prove of service to those in charge of cables for the transmission of light and power. The localisation of faults has been very fully investigated, including the different degrees in which the various methods are affected by the presence of a second fault or of general leakage.—*Extract from Preface.* Demy 8vo, fully illustrated. 10s. 6d., post free; abroad 11s.

"Submarine Cable-Laying and Repairing."—By H. D. Wilkinson, M.I.E.E., &c., fully illustrated; price 12s. 6d.

"The Students' Guide to Submarine Cable Testing."—A new work by Messrs. H. K. C. Fisher and J. C. H. Darby, with the above title, is now ready, price 6s. net; abroad, 6s. 3d. This work is intended to serve as a guide to operators already in the telegraph service, and to those who desire to enter that service. The great cable companies now insist that their operators and probationers shall pass certain examinations in electrical subjects. The book is very fully illustrated. *Second Edition now ready.*

"Practical Notes for Electrical Students."—By Messrs. A. F. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free.

"Electro-Chemistry."—By Dr. G. Gore. Third Edition. Price 2s., post free.

"Electric Motive Power," by Albion T. Snell, contains the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 280 illustrations. Price 10s. 6d., post free; abroad, 11s.

"Wireless Telegraphy: Signalling across Space without Wires by Electric Waves."—By Dr. O. J. Lodge, with many original illustrations. *Enlarged Edition*, 2s. 6d. net, 2s. 9d. post free.

"Laboratory Notes and Forms."—With the above title we have ready the New Edition of a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators and Students. The object of this series is the saving of the time of the Teacher and his Assistants, and to serve as a record of the work done by the Student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen net; in sets of any three, 1s. net; or the set of Twenty (Elementary or Advanced) Exercises can be obtained, price 5s. 6d. net. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. net; or in handy portfolio, price 12s. net; or bound in strong cloth case, price 12s. 6d. net. Strong portfolios can be had, price 1s. each.

NOW READY.—The cheaper edition of Dr. J. A. Fleming's "Electrical Laboratory Notes and Forms." These cheaper Forms have been prepared for the use of students and teachers at the Polytechnic and other science classes throughout the country. The demand for the original set of these Notes and Forms has led to a request for a cheaper set for use at the day and evening classes at many of the technical institutes. These new Forms, which differ only from the higher-priced set in being printed on smaller and cheaper paper and with less space for tabulated records, are issued at half the price of the original set.

Digitized by Google

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready. Price 7s. 6d.; abroad, 8s.

"THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS."—Edited and enlarged by W. Worby Beaumont. Price 3s. 6d., post free.

"THE ART OF ELECTROLYTIC SEPARATION OF METALS."—A second issue of Dr. Gore's book is now ready, price 10s. 6d., post free.

"THE MANUFACTURE OF ELECTRIC LIGHT CARBONS."—A Practical Guide to the establishment of a Carbon Manufactory. Fully illustrated. price 1s. 6d.; post free, 1s. 9d.

"THE BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH, 1896-97." A valuable, up-to-date compilation. Being an attempt to classify the data relating to X-Ray work. This work contains a quantity of general as well as special information bearing upon the whole subject of electrical discharge research. Price 5s., post free; abroad, 5s. 3d.

"LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS."—By F. C. Raphael. Price 5s., post free; abroad, 5s. 6d. Prospectus on application.

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book, by Messrs. W. Geipel and H. M. Kilgour; price 7s. 6d.; by post, 7s. 9d.; abroad, 8s. A fine large paper edition with wide margins for notes can also be supplied. Price 12s. 6d.; post free, 13s.; abroad, 13s. 6d. *New Edition in the press.*

"THE ALTERNATE CURRENT TRANSFORMER," Vol. I.—By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. *New Edition.* Price 12s. 6d., post free. Vol. II., price 12s. 6d. post free, is also ready.

"ELECTROMAGNETIC THEORY."—By Oliver Heaviside. Vol. I., price 12s. 6d.; post free, 13s.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free.

"THE ELECTRICIAN" PRIMERS.—In Two Volumes. Vol. I., Theory. Vol. II., Practice. Price, stout paper cover, 2s. 2d. each, post free; cloth 2s. 9d. Single Primers, 3d. each, post free.

"ARMATURE WINDINGS OF ELECTRIC MACHINES."—By H. F. Parshall and H. M. Hobart. This work has been compiled from notes made by Mr. Parshall in his capacity as Chief Designing Engineer of the Edison and General Electric Companies of America, and is intended to serve as a working treatise on dynamo design. Large 4to, 370 pages, 140 full-page illustrations and 65 full-page tables, 30s., post free.

"DRUM ARMATURES AND COMMUTATORS," by Mr. F. Marten Weymouth, also ready. Price 7s. 6d.; abroad, 8s. Prospectus on application.

"THE POTENTIOMETER AND ITS ADJUNCTS": A Universal System of Electrical Measurement.—By W. C. Fisher. Fully illustrated. Price 6s., post free; abroad, 6s. 6d. Digest post free.

"MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY."—By R. Tremlett Carter, C.E., M.I.E.E. Price 12s. 6d., post free; abroad 13s. 6d. Prospectus post free.

IN THE PRESS.

"THE ELECTRIC ARC."—By Mrs. Ayrton.

"THE MANUFACTURE OF CARBONS FOR ALL ELECTRICAL PURPOSES."—By Francis Jehl.

"ELECTROMAGNETIC THEORY." By Oliver Heaviside. Vol. II.

"SECONDARY BATTERIES, THEIR DESIGN AND MANUFACTURE."—By E. J. Wade.

"PRIMARY BATTERIES: THEIR CONSTRUCTION AND USE."—By W. R Cooper.

"PRACTICAL TELEPHONY."—By Dane Sinclair and F. C. Raphael.

"'THE ELECTRICIAN' WIREMAN'S POCKET-BOOK."

"The Electrician" Electrical Trades' Directory and Handbook.—An important announcement in connection with the 1899 issue of the "Big Blue Book" will be found in an advertisement on another page of the present issue, to which our readers will please refer.

TENDERS INVITED.

The *Leeds* City Council require tenders for the supply of underground conductors, switchboards, &c., in connection with the extension of their electric tramways. Additional particulars are given in an advertisement elsewhere. Plans and specifications may be obtained from the city engineer, Municipal Buildings, Leeds, or from Messrs. Hopkinson and Talbot, 26, Victoria-street, Westminster, S.W. Tenders, addressed to the town clerk, must be in by 10 a.m. of the 29th inst.

The Committee of Visitors of the *Cumberland* and *Westmoreland* Asylum invite tenders for the supply and erection of an electric tell-tale clock, with 30 stations. Further particulars can be had from the Medical Superintendent and tenders must be sent in to the Committee, Garlands Asylum, Carlisle, not later than 2nd Jan. next. Some further particulars are given in an advertisement.

The *Glasgow* Corporation invite tenders for providing and erecting generating plant at one or other of their new electricity works, including two 200 I.H.P., two 400 I.H.P., three 1,100 I.H.P. and two 2,200 I.H.P. engines, with dynamos and condensing plant. Copies of specification, &c., may be obtained from the city electrical engineer (Mr. W. A. Chamen), 75, Waterloo-street, and tenders must be lodged with the town clerk (Sir J. D. Marwick), City Chambers, Glasgow, by *Saturday, Jan. 21.* Some additional particulars are given in an advertisement.

The Corporation of *Sunderland* require tenders for the supply of three 125 kilowatt, direct current, high speed, steam dynamos. Tenders to the office of the town clerk (Mr. Fras. M. Bowey), by noon, 30th inst.

The Corporation of *Dublin* invites tenders for the supply of a high-tension single pole switchboard. Tenders to Mr. Henry Campbell, City Hall, Dublin, by 10 a.m. of 28th inst.

The Corporation of *Burnley* invite tenders for the supply and delivery of underground cables. Tenders to Town Hall, Burnley, by Jan. 10.

The *Edinburgh* City Council require tenders for the supply of switchboards and boosters for their Macdonald-road electricity station. Tenders to Mr. Thomas Hunter, W.S., City Chambers, Edinburgh, by *Monday, Jan. 9, and not Jan. 2* as previously advertised. See advertisement.

The *Londonderry* Corporation require tenders for arc lamp globes and carbons for the year ending Dec. 31, 1899. Tenders to Sir R. N. Chambers, Kt., Guildhall, Londonderry, by 30th inst.

The Commissioners of the Burgh of *Stirling* invite tenders for the following:—(1) Lancashire boilers, with mechanical stokers; (2) engines, dynamos, pumps, steam pipes, &c., Green's economiser and tools; (3) storage batteries; (4) switchboard and boosters; and (5) arc lamps. Tenders to Mr. Thomas L. Galbraith by Jan. 2.

Hull Corporation require tenders for pipes and fittings for power station and condensing main from dock; builder's works for two car sheds, &c.; steel roof trusses, columns, &c., for sheds. Tenders to chairman Works committee by 30th inst. for the pipes and fittings, and by Jan. 13 for the remainder.

The *Islington* Vestry invite tenders for certain building work in connection with the extension of their electricity station at Edengrove. Tenders to the Vestry clerk, Upper-street, N., by 28th inst.

The Cleveland and South Durham Assets Co. require tenders for the erection of an electricity generating station at *Saltburn-by-the-Sea.* Tenders to the architect, 59, High-street, Stockton-on-Tees, by 27th inst.

The *Tunbridge Wells* Town Council require tenders for the erection of telephone fire alarms within the borough. Tenders to Town Clerk by Dec. 11.

Tenders are required for wiring the new buildings and other parts of the Castle, *Winchester.* Tenders to clerk to County Council, at the Castle, by the 27th inst.

Tenders are invited for wiring shop premises in Silver-street, *Halifax,* for the Cash Supply Stores (Limited).

The *Shanghai* Council invite tenders for a concession, for a period of thirty years, for the exclusive right of establishing and working a telephone system in Shanghai. Particulars of Messrs. J. Pook and Co., 8, Jeffrey's-square, London, E.C. Tenders to Mr. J. O. P. Bland, Shanghai, by noon of March 31.

The *Shanghai* Council also invite tenders for a concession for constructing and working about 23 miles of electric tramways on the trolley system. Particulars from Messrs. John Pook and Co., 8, Jeffrey's-square, London, E.C. Tenders to Mr. J. O. P. Bland by noon of March 15, 1899.

Tenders are being invited until Jan. 4th by the *Norwegian State* Railway authorities for the supply of 3,500 porcelain insulators, 1,000 zinc cylinders and 10,000 zinc rods for primary batteries, four kilometres of insulated copper wire, and 14 tons of telegraph wire. Tenders to the Expeditions Bureau der Verwaltung der Staats-Balnen, Jerntanetorvet, 8-9 Christiania.

TENDERS RECEIVED AND ACCEPTED.

The *Coventry* Electric Light Committee have accepted the tender of Mr. C. H. Barber for erecting five transformer sub-stations at £818.

The Watch and Lighting committee of the *Aberdeen* Corporation have accepted the tender of Messrs. Shirras, Laing and Co. for the electric lighting of the new fire engine station.

The *Douglas* (Isle of Man) Town Council have accepted the tender of Messrs. Veritys (Limited) for wiring the municipal buildings and public library at £312.

The *Bristol* Docks committee have accepted the tender of Messrs. Willway and Sons for the wiring of their engineer's offices.

The Lighting committee of the Barnsley Town Council recommends the following tenders for the supply of electric lighting plant for acceptance:—

(1) Lancashire boilers and Green's economiser, and setting of same, W. Arnold and Co., £3,280; (2) Engines, dynamos, switchboard, condensers, feed-water pumps, balancing transformers, boosters, piping, tanks, crane, wiring of electricity supply works, and engine, &c, foundations, Johnson and Philips, £8,030; (3) Secondary batteries and accessories, Pritchetts and Gold, £1,319; (4) Feeder and distributing mains (solid system), and (5) Potential leads, network and service boxes, and service connections, British Insulated Wire Co., £6,322 4s, 2d., and £110 for maintenance.

Digitized by Google

The *Morecambe* District Council have accepted the tenders of Thomas Parker (Limited) at £1,955 and Messrs. C. A. Parsons and Co. at £2,525 for the supply of additional plant at the electricity works. The Callender Co. have obtained the contract for low-tension cables.

The *Llanrwst Electricity Supply Co.* have accepted the tender of Messrs. Calvert and Co., of Manchester, for the electric lighting of Llanrwst.

The *Shoreditch* Vestry have accepted the tender of the British Insulated Wire Co., for supplying, drawing in and jointing the cable required for the Haggerston extension, at the following rates:—1°/ conductor at 11s. 6d. per yard, ·75°/ at 9s. 4d., ·5°/ at 6s. 5d., and ·25°/ at 3s. 8d.

APPOINTMENTS VACANT AND FILLED.

The Carlisle Corporation require an assistant engineer for their electricity department. Salary £130 per annum. Also a switchboard attendant and two engine drivers (accustomed to Willans' engines). Further particulars in advertisements elsewhere. Applications to the city electrical engineer (Mr. C. D. Burnett), James-street, Carlisle, by 31st inst.

Applications are invited for the post of evening instructor in electric wiring at the Northampton Institute, Clerkenwell, E.C. Applications by Jan. 3. Further particulars from the principal, Dr. R. Mullineux Walmsley. See also advertisement.

The Tramways committee of the Manchester Corporation require a competent engineer to assist in carrying out engineering work in connection with the permanent way. Salary £200 per annum. The committee also require a temporary engineering assistant. Wages 50s. per week. Applications to the Chairman of the committee, Town Hall, Manchester, in each case, by Saturday, 31st inst. See advertisement.

The London County Asylum, Bexley (Kent), require a working foreman engineer to take charge, under the asylum's engineer, of the engineering appliances, including heating, electric light, laundry and cooking. Salary £12. 10s. per month, and quarters. Forms of application can be obtained from Mr. R. W. Partridge, clerk to the Asylums Committee, 21, Whitehall Place, London, S.W., and applications have to be sent in by 9 a.m. on Wednesday, Jan. 11. Some further particulars are given in an advertisement on another page.

The Urban District Council of St. Anne's-on-the-Sea, Lancs., invite applications for the appointment of electrical engineer to design and superintend the erection of an electricity supply station and the laying of mains, and to afterwards take charge. Commencing salary £170 a year, advancing to £200 and beyond, proportionally to the success of the undertaking. Applications to Mr. Thomas Bradley, clerk to the Council, by 5 p.m. of Jan. 2nd. See also an advertisement elsewhere.

The Blackheath and Greenwich Electric Light Co. require a secretary. Applications to the Company, 11, Charing Cross-road, London, W.C., by Dec. 30.

BUSINESS NOTICES.

Messrs. Warren and Hammond, electrical and mechanical engineers, of Bridge-crescent, Sunderland, have dissolved partnership. The business will be carried on by Mr. W. E. Hammond in his own name.

BANKRUPTCIES, LIQUIDATIONS, &c.

At the London Bankruptcy Court on Monday, before Mr. Registrar Hope, Robert Martin Houldsworth, 7, Fenchurch-avenue, E.C., was examined. Gross liabilities £19,435, unsecured £19,189, and assets £3,909. Failure attributed to loss in connection with the promotion of the British Steam Generator and Refuse Utilisation Co. (Limited) formed to work Levett's patent for producing electric current from town refuse.

Under the failure of Edward Baldwin Pym, electrical engineer, late of Bar-chambers, Scarborough, the first meeting of creditors was held on Monday, at the London Bankruptcy Court. Debtor has not surrendered under the proceedings, and the meeting was adjourned for three weeks. Debtor is said to be at Monte Carlo.

A receiving order has been made against John Evelyn Liardet, engineer, 16, Hyde Park-gate, Kensington-road, London.

The creditors of the London Provincial Electrical Co. (Limited) (in liquidation) are:—

J. Crawford	£3,965	S. J. Dixon and Co.	£20
E. McLaughlin	175	Birmingham Accessories Co.	19
L. G. Russell	175	Binney and Son	18
H. S. Blaydes	173	Braulik and Co.	17
Birmingham Brass Foundry.	146	Rhodes and Co.	14
Ellis and Ward	58	J. Sykes	14
Paddison, Son and Co.	57	Beanland and Perkin	13
W. T. Glover and Co.	57	Bayliss and Co.	13
— Spooner	26	A. R. Dean (Limited)	12
Crompton and Co.	23	British Insulated Wire Co	10
Gilman and Son	21		

Lionel Riley, trading at 10, Throgmorton-avenue, E.C., and 168, Upper-street, Islington, N., London, as L. V. Riley and Co., engineers and electricians, and at 2, Holloway-road, N., as the Highbury Art Metal Co., has "found it necessary to place his financial matters in his solicitor's hands." A meeting of creditors is to be held at the Guildhall Tavern, London, E.C., on Wednesday, 28th inst., at three o'clock. Messrs. Harries, Wilkinson, and Raikes, 38, Nicholas-lane, E.C., act in the matter.

At a meeting of Pearson's Automatic Fire Indicator Co. (Limited), on Nov. 24, it was resolved to wind up the company voluntarily, Mr. K. L. Skinner is liquidator.

Patent Amendments.—Notice is given in advertisements elsewhere that Mr. F. G. W. J. Adams has applied for leave to amend specification of Letters Patent (No. 19,431 of 1897) for "improvements in or relating to electric lamps," and also specification of Letters Patent (No. 11,526 of 1891) for "improvements in and connected with portable electric lamps and primary batteries, and lenses for deflecting light to be used therewith." Mr. A. R. Adams proposes to amend specification of Letters Patent (No. 3,831 of 1897) for "improvements in or relating to electric batteries." Mr. G. W. H. Adams proposes to amend specification of Letters Patent (No. 7,696 of 1888) granted to Theophilus Coad for an "improved portable incandescent electric safety lamp." Notices of objection must be lodged in each case by Jan 14 next.

Plant for Sale.—As elsewhere announced, the plant, machinery and stock of electro-plating and electric lighting works, in Blackburn, are for sale.

Award.—A bronze medal has been awarded to the Stewart enclosed arc lamp at the Turin Exhibition, 1898. This was, we are informed, the only medal awarded to enclosed arc lamps at the exhibition.

Refuse Destructors and Forced Draft Boiler Furnaces.—The Horsfall Furnace Syndicate (Limited) has established a London office at 36, Great George-street, Westminster. The firm have at the present time in hand a number of important contracts for the supply and erection of refuse destructors for the Corporations of Ashton-under-Lyne, Huddersfield, Ramsgate, West Hartlepool and St. Heliers, Jersey; the County Councils of Lanarkshire and Cheshire, the Vestries of St. Luke's and Fulham (London), Strand Board of Works, the Pembroke Commissioners (Dublin), the Metropolitan Asylums Board, H.M. Government, and the Irish Board of Works. Most of these contracts include complete steam-raising plant for use in connection with public electric light and power stations.

Calendars.—The Indo-European Telegraph Co. send a handy hanging sheet calendar with tear off pad for 1899, which gives the tariffs for messages over the company's system.

Exports of Electrical Apparatus and Material.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from Dec. 14 to Dec. 20, with the ports of destination:—

Australasia—Adelaide, £33; Auckland, £223; Brisbane, £129; Hobart, £103; Launceston, £60; Melbourne, £360 (telegraph wire); Perth, £49; Sydney, £1,665; Wellington, £628 (including £579 telegraph material). *Belgium*—Antwerp, £65; Ghent, £195; Ostend, £36. *British Guiana*—Demerara, £10. *Burma*—Rangoon, £92. *Canada*—Halifax, £27. *Ceylon*—Colombo, £79. *China*—Shanghai, £177 (including £147 telegraph material). *Denmark*—Copenhagen, £23. *Egypt*—Suez, £516 (telegraph apparatus). *France*—Boulogne, £60. *Germany*—Hamburg, £120. *Gibraltar*, £82. *Holland*—Amsterdam, £55. *India*—Bombay, £240; Calcutta, £845. *Malta*—£223. *Norway*—Christiania, £45. *South Africa*—Cape Town, £144; Chinde, £16; Durban, £29; East London, £361; Port Elizabeth, £95. *Spain*—Vigo, £45 (telegraph apparatus). *Straits Settlements*—Singapore, £117 (telegraph material). *United States*—New York, £36. Total, £6,983, against £21,433 in the corresponding week last year (Dec. 15 to Dec. 21).

MUNICIPAL, FOREIGN AND GENERAL NOTES.

Accrington.—The General Purposes committee having approved the electric lighting and refuse destructor scheme, the Town Council will at its next meeting be asked to proceed with the scheme at once.

Asylum Lighting.—The Natal Government Asylum has been provided with an electric lighting installation. The capacity of the plant is about 300 16-c.p. incandescents. The work was executed under the supervision of Mr. Oswald Swete.

Barnsley.—The Town Council on Tuesday accepted tenders for the supply of electric lighting plant and for the erection of electricity supply buildings.

Bangkok.—The Union Elektricitäts Gesellschaft, of Berlin, has acquired the works and undertaking of the Bangkok Electric Light Co., and the concession has been prolonged for 40 years.

Digitized by Google

Belfast.—At present there is an equivalent of 35,004 8-c.p. lamps connected to the electric light mains, and applications are in hand for 5,649 additional lamps.

Bermondsey (London).—The Vestry will oppose the application of the County of London Company to Parliament for power to lay trunk mains through Bermondsey. The districts affected by the Company's proposal are Bermondsey, Deptford, Lambeth and Lewisham.

Blackburn.—The Corporation have agreed to join with the Darwen Corporation in purchasing the steam tramways connecting the two towns. The purchase price is £48,500. The line will be equipped for electric working.

Blackpool.—Various extensions of the tramway system are to be carried out at an estimated expenditure of £70,000. The scheme, which affects all the principal thoroughfares in the town, was sanctioned at a special meeting of the Town Council on Monday, when it was decided to obtain a Provisional Order for carrying out the work.

Bolton.—The Lighting superintendent has been instructed to prepare a comparative statement of the cost of lighting the streets by arc lamps and by gas. This is the outcome of a proposal of the Electricity committee to adopt arc lighting in the principal streets of the borough.

Brentford.—The Middlesex County Council are taking steps to obtain clauses excluding Brentford and Kew county bridges from the operation of the proposed Brentford electric lighting scheme, or they threaten opposition to the application for a provisional order.

Brighton.—The Town Council have increased the salary of the mains superintendent (Mr. Fowler) from £3. 10s. per week to £225 per annum, rising to £250 at the end of 12 months. The salary of Mr. Tapper, inspector of house fittings, has been increased from 55s. per week to £175 per annum, rising to a maximum of £250 per annum. The salary of the chief clerk (Mr. Joyce) has been increased from £2. 10s. per week to £150 per annum. The question of the appointment of a deputy-manager to take charge of the undertaking in Mr. Wright's absence or illness has been postponed.

Bury St. Edmunds.—The Lighting committee have formulated a modified electricity scheme, and the Local Government Board are to be asked to sanction a loan of £14,000 for establishing works for supply of current in the compulsory area.

Camborne.—The Town Council have assented to the application of the Camborne Electricity Supply Co. for a provisional order, reserving the usual purchase rights.

Carlisle.—The Carlisle Corporation have offered to supply Messrs. Cowans, Sheldon and Co. with electric current for power purposes at 2d. per unit for the first 100,000 units per annum, and a sub-committee has been appointed to fix the price in the event of more than 100,000 units per annum being required.

Chatham.—Mr. John Hewett (of Harrap, Hewett and Duffield), consulting engineers, has been appointed consulting engineer for the electric lighting of the new town hall and municipal buildings.

Chester.—A Local Government Board enquiry was held here on Friday into the application of the Corporation to borrow £20,000 for electric lighting extensions. The Town Clerk stated that the electric lighting undertaking had been remarkably successful, in fact he asserted that this undertaking was the most successful in the county. There were numerous applicants for current and the city electrical engineer (Mr. F. Thursfield) had been instructed to report upon the estimated cost of the extension of the cables into various districts in the city. It was therefore absolutely necessary that the money asked for should be obtained to enable the work to be proceeded with.

Cork.—There seems to be a friendly rivalry between the various religious denominations as to the introduction of the electric light into their respective places of worship, several of which are already wired.

Devonport.—A special meeting of the Council is to be held to consider a proposal to purchase the undertaking of the local tramways company.

Dublin.—In deference to the wishes of the Corporation the Dublin United Tramways Co. have discontinued the use of trailer cars within the city.

Ealing.—The District Council have instructed their electrical engineer to prepare specifications for two additional 500 H.P. steam alternators and other extensions of the electricity works. The estimated cost of the extensions is £14,700.

Edinburgh.—The Simplex Electric Conduit Syndicate have submitted a proposal to the Town Council for introducing their system of electric traction on the Edinburgh-Portobello tramways.

Electric Traction in Italy.—The Italian Ministry for Public Works recently decided to construct a number of secondary railway lines, of a total length of over 370 miles, amongst which is an electric line from Milan to Lecco. The concession for constructing this line has been granted to the Electrical Trust, which is backed by Messrs. Ganz and Co., the Hungarian Credit Bank, the Berlin Union Elektricitäts Gesellschaft, and the Banca Commerciale of Milan.

Epsom.—A special meeting of the Town Council will shortly consider a recommendation that Mr. W. C. C. Hawtayne be appointed to prepare plans and estimates of an electric lighting scheme for the district.

Glasgow.—An agreement has been entered into by the Glasgow Corporation with the Partick authorities for a transfer of the Partick provisional order (1893) and a sub-committee has been appointed to arrange, if possible, terms for the purchase of the undertaking of the Kelvinside Electricity Co.

The Tramways sub-committee recommend that, owing to the difficulties presented locally to the adoption of the conduit system, especially in consequence of the nearness of the roof of the Central Railway tunnel to the street level, it is inadvisable to experiment with the conduit system in Glasgow. It is recommended that the conversion of the whole of the lines from horse traction to the trolley system be proceeded with as soon as possible.

Gloucester.—A Local Government Board inquiry was held on Wednesday into the application of the Town Council to borrow £50,000 for electric lighting purposes. The consulting engineer (Mr. Robert Hammond) submitted details of the scheme, to which there was no opposition. The works are to be erected on the Bearland estate. It is intended to erect 36 arc and 286 double 16-c-p. incandescents for public lighting, besides supplying current for private lighting. The total public lighting estimated for is 158,950 units, and for private lighting 187,500 units, or a total of 346,000 units per annum. The estimated revenue is—for private lighting, £3,906; public lighting, £1,987; meter rentals, £150. The total working cost is estimated at 1·85d. per unit, £2,670, or a gross profit of £3,375, which, after deducting charges on loan and sinking fund (£2,426. 5s.), leaves a margin of £946. 15s.

Grays (Essex).—In a preliminary report by the Council's electrical engineer (Mr. A. H. Preece) it is stated that there would be no difficulty in competing with gas at 4s. 4d. per 1,000ft., even with a charge of 7d. per unit for electric current. The cost of an electric lighting scheme would be over £10,000. It is proposed to erect 188 public incandescent lamps. The output of the proposed works for the first year is estimated at 48,000 units for street lighting and 32,000 for private lighting, and the upkeep expenses are put at £950.

Greenock.—The Police Board have adopted Mr. S. E. Fedden's electric lighting scheme, some particulars of which were given in our last issue.

Hampstead (London).—The Vestry have authorised the Lighting committee to prepare plans for the extension of the electricity work, with a view to the provision of additional plant equal to 4,000 H.P. The net profits of the undertaking are to be set aside to form a reserve fund until this reaches 10 per cent. on the capital outlay.

Inquest.—The Southampton Borough Coroner (Mr. Wm. Coxwell) resumed the inquest on Tuesday into the death of Walter Day, an electrical jointer in the employment of Messrs. W. T. Glover and Co., who was killed on the 12th inst., while engaged in jointing a cable. Deceased was about 30 years of age, and was working at Southampton on behalf of his company. He was called on to repair a joint in a live high tension cable. He had no gloves, and accidentally touching the exposed part of the main, he died almost instantaneously from the shock. The jury returned a verdict of "accidental death," recommending that gloves should always be used.

Light Railways.—Sir Courtenay Boyle, K.C.B., on Monday heard the objections to the confirmation of the order of the Light Railway Commissioners to construct a light (electric) railway from the Portsmouth tramway terminus to Cosham, Horndean and Portsdown Hill. Mr. Balfour-Browne, Q.C., appeared for the objectors (the London and South-Western Railway Co.), and suggested that the promoters should be compelled to construct a bridge over the South-Western line at a cost of between £3,000 and £4,000. Judgment reserved.

Application is to be made by the Reigate Corporation for the construction of a light (electric) railway between Reigate and Redhill.

Limehouse (London).—The question of applying for a provisional order had been under consideration of the District Council, but the matter has been further adjourned.

Lincoln.—A sub-committee has been appointed to confer with the Tramway Company on the purchase of the tram lines, and also as to the desirability of adopting electric traction.

London City Lighting Contracts.—Mr. Alpheus Cleophas Morton, common councillor of the City of London, notwithstand-

Digitized by Google

ing that he has had time to seriously consider his statement before the Streets committee that the contracts for the lighting of the City of London are "null and void," as late as Tuesday last repeats his opinion in a letter addressed to the daily press on the subject of a reported conference between the City authorities and the City of London Electric Lighting Co.

London County Council.—At Tuesday's meeting it was announced that the Treasury had sanctioned loans of £11,020 and £10,000 to the Vestries of Hammersmith and Newington respectively.

The Establishment committee of the Council has been authorised to expend £450 in the erection of an electric lift. It was announced that the cost of electric power would be considerably less than that of hydraulic power for working the lift.

The Fire Brigade committee reported that in February last the Council accepted the offer of the Post Office to provide portable telephones on fire alarm posts, to enable firemen to use the apparatus for the transmission of telephonic messages, and that their chief officer (Commander Wells) had since obtained provisional protection for an improved appliance to effect this object. The trials made of the apparatus had been very satisfactory. The chief officer has suggested that extended trials shall be made, and the Post Office have notified their willingness to fit fire alarm posts with microphones and plug holes for telephones and to provide plug holes in the corresponding indicators in the fire stations for an annual rental of £31. 15s. per 50 posts. The comm ttee were authorised to enter into an arrangement with the Post Office to this effect.

Mr. Benn, Chairman of the Highways committee, stated that the Nottingham Corporation had refused to release Mr. Alfred Baker from his engagement for six months. Meantime, a sub-committee of five members of the Highways committee has been appointed to carry on the business, the sub-committee consisting of Sir John Hutton, Ald. Hubbard and Messrs. Westacott, Parker and Benn.

Messrs. Benn, Parker, Beachcroft, Dickinson, Johnson and Thornton were appointed to represent the Council at the telephone conference at the Guildhall, London, convened by the City Corporation.

The Parliamentary committee recommended "that the Parliamentary committee be authorised to seek powers in the next session of Parliament, either by a separate bill or by the insertion of provisions in the General Powers bill, to enable the Council to use electrical traction on all or any of its tramways, and for that purpose to reconstruct the tram lines, and erect and place in, under, or over the roads such apparatus as may be necessary." The recommendation was approved.

Lowestoft.—Mr. W. C. C. Hawtayne has been instructed to prepare a report for the Town Council on the question of the supply of current to the Light Railway Company.

Llandudno.—The Great Orme Tramway Syndicate have decided to accept the offer of a London syndicate to purchase their undertaking and to introduce electric traction.

Llanrwst.—The work in connection with the electric lighting scheme for this town is to be proceeded with immediately.

Marylebone (London).—The Guardians have accepted the recommendation of the Workhouse committee to advertise for tenders for the electric lighting of the front blocks of the workhouse. The estimated cost is £1,200.

Moss Side.—The District Council have been informed by the Manchester Corporation that a supply of electric current for the Moss Side district will shortly be available.

Morecambe.—At the last meeting of the District Council tenders were accepted for the supply of an additional plant for the electricity works. The draft agreement with Messrs. Stoddart and Co. for wiring the premises on the "easy" system was considered, but was sent back for amendment.

Newton Abbott.—The Urban Electricity Supply Company, which is applying for a provisional order for this town, has succeeded in arranging terms with the District Council, and formal consent to the application of the company has been given. Mr. Handcock, of Messrs. Handcock and Dykes, acted as consulting engineer to the Council.

Paddington (London).—At Tuesday's meeting of the Vestry, the Electric Light committee reported that after considering their correspondence with the Metropolitan Electric Supply Co., unless the Vestry were prepared to purchase the undertaking of the company, no advantage would be derived from further correspondence on the subject. Col. Barchard, Chairman of the committee, said that while they had been empowered to correspond with the company they had been given no powers to negociate for the purchase, nor had any terms been mentioned upon which the Vestry were prepared to take over the Paddington section of the company's enterprise. He thought it would now be best that the whole subject should be postponed until September next, as the Vestry could not apply for a provisional order till then, when their position might be much stronger. The neighbouring parish of Marylebone was striving to obtain the passing of a bill next session to enable them to purchase the Metropolitan Company's undertaking in their district, and they should wait to see how Marylebone fared. Sir T. G. Fardell, M.P., said he thought it would be best for the Vestry to take decided action rather than wait months before doing anything. He complained that the Metropolitan Company had failed to carry out their undertaking under the provisional order as they had not erected testing stations in accordance with their promises. When a fire took place some time ago at the company's Manchester-square station his lights went out, and he was informed by the company that he was supplied from Manchester-square, and not from Amberley-road. Also the company had failed to supply any public testing station in the parish. It was further promised that mains should be put down throughout the parish, and this had not been done. It was time that the Vestry took the matter in hand and insisted that the company fulfil its obligations. The company's £10 shares now stood at £16, and if it was known that the Vestry were desirous or likely to purchase the undertaking the shares would go up in price. It was time they seriously considered their position in this matter, and he moved that the vestry should write to the Metropolitan Co. asking whether the obligations imposed by the provisional order of 1890 were to be carried out and that the attention of the London County Council should be called to the fact that no public testing station had been provided by the company. Col. Blair pointed out that by treating the company hitherto in a civil manner the Vestry had obtained many concessions, the price for current being as low as that charged by any company in the metropolis. The company had spent something like £200,000 in the parish, therefore, if they intended to buy the Company out and secure the electric lighting in their own hands, they must be prepared to spend at least a quarter of a million of money. Sir George Harris said that, with regard to the testing station, they did not want an arrangement, such as was in existence with regard to the testing of gas, as 24 hours' notice had to be given to the gas company of the intention to test, enabling the company to put on an especially good light so that testing was useless. Mr. Smith suggested that the committee should be empowered to ascertain from an expert valuer the value of the company's plant, &c. Mr. Hunter considered the company should name the price at which they were prepared to sell, and then the Vestry could say whether it was prepared to entertain the offer or not. Finally it was decided that the Vestry were not prepared to give the committee any further instructions, the committee being left to act as they consider best. It was decided to give the Vestry's support to the proposal of the Hammersmith Vestry to oppose legislation on the lines of the report of the Joint Committee on Electrical Energy (Generating Stations and Supply).

Penny Postage.—A list is published of the British colonies and dependencies, between whom and the mother country penny postage is established on and after Christmas Day. The list includes:—

Aden.	Falkland Islands.	Niger Coast Protectorate.
Ascension.	Fiji Islands.	Niger Territory.
Bahamas.	Gambia.	St. Helena.
Barbados.	Gibraltar.	Sarawak.
Bermuda.	Gold Coast Colony.	Seychelles.
British Central Africa.	Hong Kong.	Sierra Leone.
British East Africa.	India.	Straits Settlements.
British Guiana.	Jahore.	Tobago.
British Honduras.	Lagos.	Trinidad.
Canada.	Leeward Islands.	Turks Islands.
Ceylon.	Malay States.	Uganda.
Cyprus.	Natal.	Windward Islands.
	Newfoundland.	

The Cape is, we learn, likely to be added to the list by the beginning of the new year.

Poplar (London).—The electric lighting scheme prepared by Mr. A. Blackman is to be discussed at the next meeting of the District Board of Works. The low tension continuous current three-wire system of distribution is recommended, and 54 10-ampere and 71 7½-ampere arcs are to be erected for street lighting. The charge for current for private lighting will be 5d. per unit for the first hour of maximum demand, 4d. for second hour, and 3d. for all further consumption for lighting, and 3d. for the first hour of maximum, and 1½d. for all subsequent consumption for power. The estimated cost of the scheme is £79,000, and application is to be made to the London County Council to loan this sum.

Portsmouth.—Application is to be made to the Local Government Board for sanction to borrow a further £18,000 for electric light extension purposes.

St. Luke (London).—The Vestry have decided not to oppose the application of the Smithfield Markets Electric Supply Co., for a provisional order, but the Vestry retain the right to lay their own

Digitized by Google

mains if they decide to establish electricity supply works. The Metropolitan Electric Supply Co. have decided not to proceed with their application for this district.

St. Pancras (London).—The Vestry will apply to the London County Council for a loan of £30,000 for certain extensions at the Regent's Park electricity station. The committee have been in communication with the Board of Trade respecting the supply of current to premises on the border line of the parishes of St. Pancras and Islington, and the Board intimate that they do not appear to have power to authorise the erection of overhead wires for this particular purpose. The matter, it is suggested, is one for arrangement. The Vestry will support the Hammersmith Vestry in its opposition to the powers suggested by the Parliamentary joint committee on the supply of electric energy.

Shoreditch (London).—This Vestry will also support the Hammersmith Vestry in opposing the proposal of the joint Parliamentary Committee on the supply of electrical energy depriving local authorities of their present powers over provisional orders in their districts. The Lighting committee have received an application for the supply of current to the extensive factories of Messrs. Waterlow and Sons, printers. It is estimated that 100,000 units per annum will be taken, and it is not certain that the capacity of the present plant is sufficient to meet this order. The Lighting committee recommend that Messrs. Kincaid, Waller and Manville be instructed to prepare a specification, in conjunction with the chief electrical engineer, with a view to tenders being obtained for the supply of two 750 kilowatt sets of engines and dynamos, boilers and switch gear in connection with the proposed new generating station. This recommendation was, however, discussed in private, and we are unable to report the Vestry's decision.

Southtown (Great Yarmouth).—Messrs. Jewson and Sons, timber importers, have recently put down plant for the electric lighting of their establishment. The installation comprises 7 arcs and about 70 16 c.p. incandescents. The installation has been provided by Messrs. Whitmore and Binyon.

Surbiton.—The Board of Trade have deferred the question of the revocation of the District Council's provisional order for 12 months.

Telegraphs in the Soudan.—It is stated that after Lord Kitchener's arrival at Omdurman, the construction of overhead telegraph lines will be begun to Fashoda and the Sobat river, also between Kassala, Gedaref and Sennar.

Sunderland.—Mr. John F. C. Snell, A.M.I.C., M.I.Mech.E., M.I.E.E., has been appointed by the unanimous vote of the Corporation to be engineer for the construction and subsequent running of the Corporation tramways, a bill for which is now before Parliament. Mr. Snell has to be responsible for the carrying out of the whole of this contract, including the permanent way and car sheds, as well as the purely electrical overhead and other equipment. Mr. Snell also has in hand large extensions to the present lighting station, both for lighting and traction purposes, and is changing the existing system over to 440 volts. The Council have agreed to pay Mr. Snell 100 guineas for his tramways report, and his present engagement is to be terminated, and a further five years' agreement entered into, on the following rates of salary:—First year, £600; second year, £700; third year, £750; and fourth and fifth years, £800.

Tasmanian Customs Duties.—By the recent re-arrangement of the Customs' tariff of Tasmania the following duties are now levied on machinery, apparatus, &c., imported into the colony in connection with electric light work:—An *ad valorem* duty of 10 per cent. on cables and mains, transformers, insulators, dynamos, motors, engines, engine fittings, boilers, engine packing, boiler composition and railway and tramway plant and material.

Towyn and Aberdovey.—Col. Ruck has submitted particulars of a scheme for the electric lighting of these districts. The total expenditure entailed would be about £16,000. The scheme has been referred to the Towyn and Aberdovey committees for consideration and report.

Whitechapel (London).—The District Board of Works have appointed Mr. Arthur Wright their engineer for 5 years at a salary of £600 per annum, to carry out their electric lighting scheme.

Wigan.—The Electric Lighting committee have decided to appoint an electrical engineer to carry out the proposed electricity lighting supply scheme.

Wolverhampton.—A town's meeting, held on the 19th inst., unanimously approved the bill which is being promoted by the Corporation. Powers are being sought for the construction of additional and the electrical equipment of the whole of the tramways, and also for power to wire houses and let electric light fittings, &c., on hire.

Wrexham.—By a majority of two the Town Council have decided to oppose the scheme for the construction of electric tramways in this district.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by Mr. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom all information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete Specifications. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

November 22, 1898.

24,593. O. Y. RHODES and THE MINERS' LAMP ELECTRIC LIGHTING CO. (LIMITED). Halifax. Improvements connected with the lighting of miners' and other lamps by means of an electric current.
24,605. W. H. HANSON. London. Improvements in secondary battery plates, grids and the like.
24,641. N. H. EDGERTON and A. H. MASTERS. London. Improvements in secondary batteries.*
24,655. E. T. GREENFIELD. London. Improvements in electric cables.*

November 23, 1898.

24,708. D. S. BURNS. Glasgow. A new or improved instrument for interlocking railway point and signal levers with electric block or train signalling switch on double lines of railways.*
24,714. R. HILL. Newcastle-on-Tyne. Improvements in or connected with trolleys for the overhead system of electric traction.
24,727. W. A. PRICE. London. Improvements in apparatus for measuring a supply of electricity.
24,734. P. PINCKNEY. Portsmouth. Improvements in electric traction.
24,747. E. HOUPIED and C. V. GIRARD. Liverpool. Improvements in or connected with electric sparking devices, more particularly for igniting devices of motors operated by explosive mixtures. (Date applied for under Patents, &c., Act, 1883, Sec. 103, June 13, 1898, being date of application in France.)*
24,757. M. WUILLOT. London. Improved manufacture of lead plates for secondary batteries.

November 24, 1898.

24,795. C. BOLLÉ. Manchester. Improved method of making insulating conduit tubes. (G. Brandt. Germany.)*
24,812. R. E. B. CROMPTON. London. Improvements in electrical meters.
24,833. S. H. SHORT. London. Improvements in means for suspending electric motors on electrically-propelled vehicles.*
24,843. W. C. P. TAPPER. London. A new or improved method of connecting shunt dynamos to the switchboards of electric generating stations.
24,855. A. U. ALCOCK. London. Method of and apparatus for electrically transmitting orders or signals suitable for use as a ship's telegraph and the like.
24,859. F. R. SIMMS. London. Improvements in electic sparking plugs for explosion engines or motors.

November 25, 1898.

24,872. J. ATKINSON. Cheshire. Improvements in electric dynamos and motors.
24,887. T. MILLAR. Glasgow. An electric alarm clock specially applicable for use in public works and other institutions.
24,905. R. BAYER. London. Preparation of hydrocyanic acid and other cyanogen compounds from rhodanic acid and its salts by means of electrolysis.
24,912. C. S. BRADFORD. Kingston-on-Thames. Improvements in and pertaining to lamps, gas and electric fittings, and the like.
24,914. F. E. CHANDLER. Kingston-on-Thames. Improvements in electric current conducting hinges.
24,949. SIEMENS BROS. and Co. (LIMITED). London. A regulating transformer for rotary phase current or polyphase current installations. (Siemens and Halske, Aktiengesellschaft, Germany.)*

SPECIFICATIONS PUBLISHED.

NOTE.—All Specifications can now be obtained at the uniform price of 8d. each.

1897.

27,509. MÖHRLE. Meter for electric current.
27,683. LANE. Electrical storage batteries.
28,726. BOOTH. Lamp and shade holders for incandescent electric lamps.
28,727. BOOTH. Insulating blocks connected with holders for incandescent electric lamps.
28,728. BOOTH. Holders for incandescent electric lamps.
30,848. TIMMIS. Operating railway points by electro motors.

COMPANIES' MEETINGS AND REPORTS.

Aron Electricity Meter (Limited).

The statutory meeting of this Company was held on Tuesday, at Winchester House. Sir JAMES PENDER, Bart., M.P., presided.

The Secretary, Mr. W. CHAPLIN, read the notice.

The CHAIRMAN, in the course of his remarks, said: As only some nine weeks have elapsed since the Company was brought under the notice of the public, we are not yet in a position to report anything definite as to the results obtained by the transfer of Dr. Aron's business into our hands. Satisfactory arrangements have been arrived at for the gradual taking over of the business from Dr. Aron, as the purchase-money could only be paid as the calls on the shares fell due; but this is a mere matter of detail, and is being satisfactorily carried out. Upon the Directors taking over the business they instructed Messrs. Price, Waterhouse and Co. to send one of their representatives to Berlin for the purpose of reorganising the books, so as to comply with the practice usual with English companies, for, although the present system was suitable for a private business, it would not have enabled the Company to watch in London, week by week, the progress of a business the bulk of which is done in Berlin and Vienna, and would not have enabled the Directors to place before the shareholders a yearly balance sheet within a reasonable time after the close of the financial year. This representative has now returned to London, having completed his object. We are making arrangements with the various branch managers in London, Vienna and Paris, for the purpose of securing the continuance of their services, and, in order to settle the respective responsibilities and to carry out the necessary improvements and increase at the factories, some of your Directors will proceed to Berlin early after Christmas. The Company have secured the lease of No. 46, Upper Thames-street, which they consider the most suitable place for their testing station and stores in London, and, owing to its convenient situation, the Directors have decided to move their offices there, which means a saving to the Company of several hundred pounds a year. I have great pleasure in informing the shareholders that the business which has been done during the last 11 months has exceeded our expectations; for instance, we are informed by Dr. Aron and Dr. Juttke, our Managing Directors, that the business on the Continent has kept up its normal steady increase, about 14,000 meters having been ordered during the last 11 months in comparison with about 11,000 during the preceding year, and the sales in England have risen from about 400 in 1897 to over 1,800 for the first 11 months of this year. The most gratifying feature of this increase does not lie in the number of meters sold, but in the fact that they have been placed with about 40 different central stations and other users, all of whom are beginning to give us repeat orders which lead us to believe that a rapid development of the business and much larger sales may be looked for during the next year. The remarkable progress of the business in England will no doubt lead very shortly to a considerable number of inquiries and orders from the Colonies, which will then become an additional source of income. You are aware that the profits derived from the business from Jan. 1 this year belong to this Company, but, as the Company only work the business on their own account from Oct. 1 last, the profits resulting from the working from Jan. 1 to Sept. 30 will go towards and considerably increase the working capital of £45,000 set aside for this purpose, as mentioned in the prospectus. The profits made from Oct. 1 will go towards future dividends, and, without taking into account the economies which we propose to introduce, and assuming only that the business maintains its present level and without allowing for any increase, there will be sufficient to pay at least a dividend of 6 per cent. on the Preference shares and 10 per cent. on the Ordinary shares.

In reply to a Shareholder, the CHAIRMAN said that the whole of the capital of the Company was underwritten, and about 30 per cent. was subscribed for by the public.

On the motion of Mr. MYERS, seconded by Mr. BEACHCROFT, a vote of thanks to the Chairman closed the meeting.

Smithfield Markets Electric Supply Co. (Limited).

The report of the Directors for the first year's working, ended Sept. 30, states that the trading account shows a profit of £759. The Directors found it necessary at the outset to discontinue the method of charging by "lump sum" contracts which had previously been in force (and which had led in many cases to extravagant use of the current), and to adopt the customary fixed rate per unit, based on the actual meter consumption. The effect of this necessary change was a loss on trading for several months. The Directors, are, however, satisfied that their policy was correct and necessary in order to establish the company's business upon a sound basis. A substantial increase in the price obtained per unit has been effected, and the total number of customers now connected shows a net gain upon the number connected at the commencement of the company's operations. The price charged per unit is still below that of any other London supply company. The working of the station and the conduct of the company's business has been carried on in a satisfactory manner. The cost of production has been substantially reduced, and when the installation of the large storage battery (with a capacity of 2,000 ampere-hours), now on order, has been completed, the cost per unit will be still further reduced. As the tendency is in the direction of increased demand, and as there is a very large scope for increase of business in the Corporation markets alone, the Directors are confident that the company will be upon a dividend-earning basis in the second year of its operations. Applications have been made to the Board of Trade for provisional orders for the adjoining areas of the City of London, the parish of St. Luke and the Holborn district. The Chairman (Mr. G. H. Brougham Glasier) has been regretfully obliged to resign his seat on the Board, owing to the fact that the Charing Cross and Strand Electricity Supply Co., of which he is also the chairman, has made an application (in competition with this company) for a provisional order for the City of London.

NEW COMPANIES, STATUTORY RETURNS, &c.

CHAMBERLAIN AND HOOKHAM (LIMITED).—This company was registered on Dec. 15, with a capital of £100,000, in £5 shares, to acquire the business now carried on by Chamberlain and Hookham (Limited), at 4, New Bartholomew-street, Birmingham, and elsewhere, to enter into an agreement with the said company and Joshua Brown (its liquidator), and to carry on the business of manufacturers of and dealers in electricity meters, electrical plant, machinery and apparatus, electrical engineers, suppliers of electricity, iron, steel and brass founders and metal workers, &c. The first subscribers (each with one share) are:—Arthur Chamberlain, J.P., John S. Nettlefold, J.P., Miss Helen Chamberlain, Philip Hookham, Frederick Hookham, Richard P. Hookham and Mrs. Margaret Nettlefold. The first Directors are Arthur Chamberlain and George Hookham.

E. J. CLARK (LIMITED).—This company was registered on Dec. 17, with a capital of £2,000, in £1 shares, to acquire the business carried on under the style or firm of Tizzard and Co., to enter into an agreement with Mr. D. R. Butters, and to carry on the business of electricians, electrical and general engineers, &c.

CLAYTON ENGINEERING AND ELECTRICAL CONSTRUCTION CO. (LIMITED).—This company was registered on Dec. 14, with a capital of £40,000, in £1 shares (20,000 Six per Cent. Cumulative Preference), to acquire the business of the Clayton Foundry Co. (Limited), and to carry on the business of mechanical engineers, millwrights, engine, dynamo and motor builders, electrical engineers, rubber and cotton machinery manufacturers, &c. The first subscribers (each with one share) are: J. P. Bedson, engineer; Tom Westgarth, engineer; R. Le Neve Foster; G. Garner, engineer; J. H. Nuttall, engineer; J. R. Garner, electrical engineer; and C. J. E. Hall. The first directors are: E. J. Byrne, R. Le Neve Foster, J. P. Bedson and G. Garner.

ENGINEERING UNDERTAKINGS (LIMITED).—This company was registered on Dec. 13, with a capital of £5,000, in £1 shares (4,500 Five per Cent. Cumulative Preference), to carry on the business of mechanical and general engineers, machinists, electricians and suppliers of electricity.

LAND AND WATER ELECTRIC POWER SYNDICATE (LIMITED).—This company was registered on Dec. 6, with a nominal capital of £10,000, in £1 shares, to acquire the business now carried on under the style of Kerbey Bowen, and to carry on the business of ship, yacht, launch and boat builders and repairers, electricians, electrical and mechanical engineers, suppliers of electricity, and manufacturers of electrical apparatus. The first subscribers, with one share each, are:—A. A. Cooper, E. R. Baines, I. H. Campion, F. B. Conyard, S. B. Saunders, T. H. Greenwood, and K. Bowen (engineer).

NILE SYNDICATE (LIMITED).—This company has been registered with a capital of £50,000 in £1 shares, to acquire and develop certain concessions, grants, &c., in Egypt; to adopt an agreement made between J. H. Bailey (as trustee for this company) and J. E. Liardet and F. H. Medhurst; and to carry on the business of a mining, smelting and metallurgical company, to construct and maintain rail and tram roads, gas and electric works, &c.

HARRY W. COX (LIMITED).—The statutory return to Oct. 17 gives the nominal capital as £2,000, in £1 shares, of which 1,505 have been taken up. Three shares have been issued, with 2s. 6d. per share paid; the full amount has been called on the others.

ELECTRICAL DEVELOPMENT AND FINANCE CORPORATION (LIMITED).—The annual return to Sept. 1, gives the capital as £500,000 in £1 shares (of which 10,000 are Deferred); 10,477 Ordinary and all the Deferred have been taken up, and the latter have been issued as fully paid; 15s. per share has been called on the 10,477 Ordinary.

MATHER AND PLATT (LIMITED).—The annual return to Nov. 15 has been filed. The capital is £200,000, in £10 shares, of which 15,000 have been taken up. Calls amounting to £9 per share have been made.

CITY NOTES.

MEMORANDA.—Bank rate 4 per cent. (since Oct. 13, 1898). Price of silver 27⅞d. per oz. (Dec. 22). Consols (2¾ per cent.) 110⅛—110¼ for money, 110 5/16—110 7/16 for account; 2½ per cent. 104—104¼ (Dec. 22). Stock Exchange Settling Days: Stocks and Shares Continuation Days, Dec. 28 and Jan. 11; Ticket Days, Dec. 29 and Jan. 12; Pay Days, Dec. 30 and Jan. 13; Mining Share Carry-over Days, Dec. 27 and Jan. 10.

AFRICAN DIRECT TELEGRAPH CO. (LIMITED).—Coupons in this company's Four per Cent. Mortgage Debentures, due Jan. 1, will be paid at Parr's Bank, Bartholomew-lane, London, E.C., and the debenture register will be closed from 26th to 31st inst. inclusive.

BRAZILIAN SUBMARINE TELEGRAPH CO. (LIMITED).—The coupons of this company's second issue of Five per Cent. Debentures, due 31st inst., will be paid at Parr's Bank, Bartholomew-lane, London, E.C.

CANADIAN, BRITISH COLUMBIAN AND DAWSON CITY TELEGRAPH CO. (LIMITED).—Letters of allotment in the £225,000 Five per Cent. First Mortgage Debenture stock of this company have been posted.

CLAYTON ENGINEERING AND ELECTRICAL CO. (LIMITED).—During the week this company invited subscriptions for 15,000 Ordinary and 15,000

Digitized by Google

Six per Cent. Preference shares of £1 each, and debentures to the amount of £15,000.

PACIFIC AND EUROPEAN TELEGRAPH CO. (LIMITED).—The coupons of this company's Four per Cent. Guaranteed Debentures, due 31st inst., will be paid at Parr's Bank, Bartholomew-lane, London, E.C.

PERTH AND DISTRICT TRAMWAYS CO. (LIMITED).—The Directors announce in their annual report that they have taken preliminary steps to enable them to adopt any system of electric traction.

PAISLEY TRAMWAYS CO. (LIMITED).—It has been decided to extend until June 22 the time for confirmation of the agreement with the British Electric Traction Co., whereby the latter could exercise their right of purchase.

ST. JAMES'S AND PALL MALL ELECTRIC LIGHT CO. (LIMITED).—The transfer registers of the Four per cent. Debenture stock of this company are closed.

SHEFFIELD ELECTRIC LIGHT AND POWER CO. (LIMITED).—A meeting of the shareholders of this company was held on Tuesday to declare a dividend for the past year, and to authorise the voluntary liquidation of the company. Ald. Franklin presided, and said the Act of Parliament obtained by the corporation for confirming the agreement for purchase received the Royal assent on the 12th Aug., and they expected the purchase would be completed by the 31st inst. The company was, under the agreement, entitled to retain a sum of £10,267. 16s. 8d. towards the dividend for 1897. Of this sum there was a balance of £803. 5s., which was undistributed in 1897. The Company was also entitled to distribute to the shareholders a dividend of 10 per cent. for the year ending 31st inst. Thus the 10 per cent. for 1898, added to the undistributed balance from 1897, gave them 14s. 11d. per share upon 4,000 shares, and 14s. 9d. per share upon the remaining 10,000 shares. It was obviously impossible to arrive definitely at a precise figure as to the purchase money, because it involved investigations into transactions which were going on more or less from day to day, but probably the shareholders would feel somewhat comforted if he told them at once what would be the result of the division of the purchase money among them. Shareholders would remember that they had the option in the agreement of taking £220 of 2½ per cent. stock, or an alternative of £213. 8s. in cash for each £100 spent. It was a fortunate thing for the company that they took this precaution, becauee from one cause or another, ever since the agreement was negotiated, municipal securities had been depreciated in the market. The result was that £220 of 2½ per cent. stock was not to-day worth £213 8s. in cash. Seeing that they had the alternative of taking either stock or cash, the Directors had determined to ask the corporation to pay the £213. 8s. in cash, instead of £220 in stock. If any shareholder felt dissatisfied with that arrangement, and would take his £213. 8s. to any sharebroker for investment, he would get considerably more than £220 per cent. in stock. On Jan. 4 liquidators would be appointed, who the following day would make their first distribution amongst the shareholders. The final distribution would work out that the value of each share, after paying the dividends declared at that meeting, would be between £17. 10s. and £18, and probably considerably nearer £18 than £17. 10s. Therefore, the shareholders would see that they would be getting, in addition to their dividend, about £17. 10s., or from that to £18 per share for each £7 of original capital. In 1893 and 1894 they had no dividend, in 1895 5 per cent., in 1896 7½ per cent., in 1897 12½ per cent., and in 1898 he supposed it would be about 10½ per cent. In 1894, when 6,000 shares were offered to the public at par, only some 4,620 were subscribed of that issue. That showed, first, that it was an uphill struggle to fight the battle of the company in its infancy; secondly, that they had overcome that struggle, and that the result of the Company's labours had been such as to supply the Sheffield public with electric current at, he believed, a price lower than that in any other city or town in the kingdom; and that they had also been able to divide a dividend among the shareholders larger than that paid by any other electric light company in the kingdom. He ventured to say that the shareholders of the company would never have any occasion in looking back upon its history to regret anything that had happened in connection with it. The resolutions were then passed.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee has appointed Thursday, 29th inst., as a special settling day in 7,440 Five per cent. £5 (£3 paid) Cumulative Preference shares (Nos. within 1 to 20,000) and 12,560 Five per cent. £5 (fully paid) Cumulative Preference shares (Nos. within 1 to 20,000) of the *Callender's Cable and Construction Co. (Limited)*, 78,000 Four per cent. £10 (£2 paid) Preferred Ordinary A shares, (Nos. 1 to 78,000) of the *Great Northern and City Railway Co. (Limited)*, and the further issue of 22,500 £10 (£4 paid) Ordinary shares, (Nos. 62,501 to 85,000) of the *Metropolitan Electric Supply Co. (Limited)*. The Committee has ordered 78,000 Four per cent. £10 (£2 paid) Preferred Ordinary A shares of the *Great Northern and City Railway Co. (Limited)*, £100,000 Four per cent. First Mortgage Debenture stock of the *London Electric Supply Corporation (Limited)*, and the further issue of 22,500 £10 (£4 paid) Ordinary shares (Nos. 62,501 to £85,000), and the further issue of 100 £10 (fully paid) Ordinary shares (Nos. 1 to 100) of the *Metropolitan Electric Supply Co. (Limited)*, to be quoted in the Official List. Application has been made to the Committee to appoint a special settling day in and to grant a quotation to £130,000 Five per cent. Debentures of the *Costa Rica Electric Light and Traction Co. (Limited)*, and to allow the further issue of 5,403 £5 (fully paid) Ordinary shares (Nos. 484,598 to 490,000) of the *National Telephone Co. (Limited)* to be quoted in the Official List.

WESTERN AND BRAZILIAN TELEGRAPH CO. (LIMITED).—This company's traffic receipts for the week ended Dec. 16 (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Co., Limited) were £2,932.

WEST INDIA AND PANAMA TELEGRAPH CO. (LIMITED).—The estimated amount of the traffic receipts of this company for the half-month ended Dec. 15 is £2,379, against £2,240 in the corresponding period of 1897.

NOTES.

THE conflict between local authorities and companies, which has been so marked a feature of electric supply affairs during the closing year, threatens shortly to break out again with intensified vigour. A premonitory symptom is a species of newspaper skirmish which is now being conducted in the interests of the local authorities, who are fond of posing as a very much aggrieved party in the strife. We have on a former occasion remarked the curiously opposite interpretations which these authorities give to the word "monopoly" according to its association with themselves or with company undertakings.

WHILE not hesitating to open up rate-aided competition with company undertakings, local authorities are raising a foolish and illogical protest against the various schemes that are being projected for the distribution of electric power over very large areas, each area embodying the spheres of influence of several petty authorities. There can be no doubt that this method of distributing power is far cheaper than by the erection of a number of small isolated networks, each with its separate generating station. Equally certain is it that such a concern will be better managed by a company than by a caucus formed out of a number of petty local authorities.

THE fixed rental system of charging for electric light has, after a lengthy trial, ceased to find favour with the Directors of the Smithfield Markets Electric Supply Co. (Ltd.). At the first ordinary general meeting, held on Friday last, it was announced that the plain and simple method of charging by meter would henceforth be used. On a blackboard, or on paper, and among symbols for constant capital and variable costs and revenue, &c., an equation showing the superiority of the rental system may appear convincing; but when the indeterminate coefficients of human wastefulness, indifference and "sheer cussedness" are put into the calculation, it is generally found best to make the consumer pay according to what he actually consumes.

WE do not intend to convey by the foregoing remarks that the tariff should be always a fixed rate of so much per unit, whatever the consumption. The Wright "maximum demand" system is, in many localities, a far better method of improving the magnitude and fruitfulness of the revenue; but then, Mr. WRIGHT'S system is merely a device for ingeniously turning to the account of the electric supply business those indeterminate coefficients of human nature which the theoretical mind is apt to ignore.

IN the concluding portion of Mr. GIBBINGS' series of articles on "The Commercial and Business Aspects of Municipal Electric Supply," published in this issue, the subject treated is not an engineering one, and consequently is often overlooked by those managing electricity supply undertakings. It is, of course, not the duty of the supply authority to sell fittings or apparatus for consuming the electrical energy furnished, although in some cases it may hire out these; but on the other hand more influence is required than that exerted by wiring contractors to secure new consumers and to introduce various applications of electricity which are profitable, especially to the central station. For such purposes the efforts of the canvasser may well be supplemented by a show-room which can, as Mr. GIBBINGS suggests, most suitably be combined with an inquiry office, and his views as to its equipment and management may be read with advantage.

WHENEVER a new application of science is brought to the notice of the public, it is followed by a number of crude suggestions as to its further possibilities, put forward with no regard to detail and oblivious of any constructive or commercial difficulties which may stand in the way of their adoption. These are for the most part put forward either by the non-technical press or by those cranks and amateurs whose futile

Digitized by Google

desire it is to act as lay-helpers to the engineering and scientific professions. Occasionally, however, a scientist or engineer of repute will be carried away by his enthusiasm over a new invention, or by his desire to have his name associated with it, and will publish schemes for the future benefit or destruction of mankind, whose fulfilment, if not utterly impracticable, must at all events be several years distant. As such we may characterise Mr. TESLA'S recent proposal to transmit energy usefully at high pressures through the upper strata of the atmosphere, and his system of automatically manipulating torpedo boats with the assistance of Hertzian waves. The unfortunate part of these fantastic proposals is that they encourage other people to rush into print, in the desire to "go one better." Thus in a recent issue of the *Electrical Engineer* of New York, Mr. FRANK J. SPRAGUE describes—*apropos* of Mr. Tesla's torpedo boat idea, although the connection is hard to find—a suggestion for the utilisation of atmospheric electricity, which he made 17 years ago when a midshipman on board the training ship "Minnesota." FRANKLIN'S kite is replaced by a balloon, fitted with collecting points, and the cable which keeps the balloon captive is connected to the primary of a transformer whose other terminal is earthed. The secondary of the transformer is connected to a "regulator" and to "translating devices," which are apparently expected to furnish a utilisable form of electrical energy. The nature of these very necessary devices is not explained.

Cable Interruptions.—	Date of Interruption.
Para—Maranham	Nov. 15. 1898

Opening of Lincoln Municipal Electric Supply Works.—The new electric supply station of the Lincoln Corporation was formally inaugurated last Friday.

The Recent Gale and the Telephone Wires.—We are glad to record that Tuesday's serious gale caused practically no disturbance to the lines of the National Telephone Co., there being only one or two instances of standards being damaged.

Errata.—In Mr. Jehl's article in our last issue, the 18th and 19th lines from the bottom of the left-hand column of p. 803 should be transposed.——In the abstract of Dr. Kallmann's Paper in the pages immediately following, the letter e has been printed throughout in the letter-press, in place of ρ.

Fire Alarm Telephone Service in New York.—We hear that arrangements have been completed for a fire alarm telephone service in New York City. Telephones will be attached to every lamp-post on which a fire alarm box already exists, thus enabling conversation to be carried on with head-quarters. Broadway will be the first street to be equipped in this manner.

Use of the Telegraph in the German Army.—The new German Army Bill proposes to make considerable improvements in the telegraph service of the German army. Three battalion staffs for the telegraph service troops will be instituted, seven companies and two-thirds in Prussia, one company in Saxony, one in Bavaria, and one-third of a company in Wurtemberg.

Train Lighting on the Midland Railway.—We hear that some coaches on the Midland Railway have been fitted experimentally with Stone's system of lighting. These are chiefly on the 5:40 express from St. Pancras and the first-class dining car on the 6:45 train. In addition to the above, a third-class dining carriage and two composite bogie carriages are being fitted with the electric light at the carriage works, a novelty in these being that the passengers will in some cases be afforded the means of turning the light in or out.

Accident on the Halifax Tramway.—An unfortunate accident occurred on the electric tramway at Halifax, on Thursday last week. It appears that the rope connected to the trolley on one car became entangled with a passenger seated on the roof of a car on the parallel track. When one of the cars moved, the unfortunate man was dragged from his seat, and fell into the road, fracturing both his arms and sustaining other injuries.

A Memorial to Lucien Gaulard.—Subscriptions are being solicited for the purpose of finding a suitable burial place for, and erecting a monument to, Lucien Gaulard, one of the pioneers of the alternating-current transformer system of electrical power distribution. Those who wish to contribute are requested to communicate with M. E. Sartiaux, President of the Syndicat Professionel des Industries Electriques, 48, Rue de Dunkerque, Paris.

220-Volt Enclosed Arc Lamp.—The General Electric Co., of America, has put on the market an enclosed arc lamp for use on 220-volt circuits. It operates with 120 volts at the arc, and takes a normal current of 2·5 amperes, and one pair of carbons are said to last from 130 to 150 hours. Owing, no doubt, to the increased length of the arc, the light is of less volume and more violet in colour than in arc lamps for circuits of lower voltage. There is a variable resistance placed at the top of the mechanism, which permits the lamp to be adjusted for use on circuits of from 210 to 250 volts.

The American Institute of Electrical Engineers and Research Work.—A committee, appointed by the American Institute of Electrical Engineers to suggest problems for research on the part of scientific schools, and to co-ordinate the results obtained, has just issued a list of 27 suitable subjects. This list suggests many useful problems worthy of investigation. But in this country Professors have little trouble in finding out sufficient objects for their students' research work; to find the requisite number of capable students and the apparatus necessary for the experiments is often not such an easy matter.

Duty on Electrical Energy in Copenhagen.—The current supplied for the electric lighting of the Osterbro railway station in Copenhagen is derived from a generating station within the free port of Copenhagen. Practically every import into Denmark has to pay duty, and electric energy is not excepted, for in this case a duty of 10 per cent. has to be paid. From the point of view of equity, however, this is quite justifiable, as the coal used at the generating station would have to pay duty in any part of Denmark except within the free port, so that the current is generated cheaper than it would be elsewhere. What makes the fact more amusing is that the Danish railways are the property of the State, so that the duty is merely paid from one State department to another.

The Automobile Club.—The Automobile Club of Great Britain and Ireland, with which is incorporated the Self-propelled Traffic Association, have arranged for an international show to be held at Richmond, Surrey, on Saturday, June 24, 1899, and continuing till the following Saturday, July 1. The show will include an exhibition of motor vehicles and accessories, time tests of motor vehicles on the track (three laps to the mile), motor cycle races, hill-climbing tests in the neighbourhood of Richmond, awards for the best design and general appearance of motor carriages, competition for commercial motor vans, omnibuses, &c., and an exhibition of conveyance of public in motor vehicles on the track. It is proposed to invite the recognised automobile clubs of the world to a congress during the show.

Motor-Car Race in France.—A short-distance hill-climbing race for motor-cars was recently organised by the paper *La France Automobile*. It was won by the heaviest among the 47 competitors, an electric carriage constructed by the Compagnie Générale des Transports Automobile. This carriage, which weighed 28 cwt., accomplished the distance of 2,000 yards in 8min. 52sec., the average gradient being 5·3 per cent. *L'Industrie Electrique* estimates that the output of the accumulators in the car must have been 15 kilowatts on an average during the 4min., which is about four times the normal listed discharge rate for a five hours' discharge. As

Digitized by Google

the maximum gradient was 10·6 per cent., our contemporary surmises that five or six times the five-hour discharge rate must have been attained on parts of the course. The battery consisted of 76 cells of the Fulmen B_{17} type.

Parsons Steam Turbines. — According to the *Pittsburg* (U.S.A.) *Times*, a large order has been received by the Westinghouse Company of America, who own the patents for these machines in the United States. The United Electric Light and Power Co. of New York, in which undertaking the Westinghouse Company is said to be largely interested, is to put down a 2,500 H.P. Parson's engine, to be followed by four other engines of similar size. The Westinghouse Air-Brake Co. are also said to be displacing the ordinary steam engines for the Parson's type, the order in this case being for three 500 H.P. machines, to drive generators and Tesla motors at the Brake Company's works at Wilmerding. When the order for the United Electric Light and Power Co.'s five machines is completed the company's 28th-street Station in New York will have a capacity of 20,000 H.P., and the smaller space occupied by the Parsons engines will, it is said, enable the company to abandon their 29th-street station.

Experiments with Electric Traction on the Paris, Lyons and Mediterranean Railway.—Experiments with an electric locomotive have recently been made under the direction of M. Baudry, the mechanical engineer of the Paris, Lyons and Mediterranean Railway Co. The locomotive had been made in the Company's workshops from the designs of M. Duvert. It is a two-axle truck, on each axle of which is mounted a 600 H.P. motor designed for a maximum current of 700 amperes at a speed up to 500 revolutions per minute. Behind the locomotive proper is a tender containing 192 accumulator cells, which are connected by conductors to the motors. In the front part of the locomotive are 18 cells, intended to drive the locomotive by itself when it is not drawing a train or its tender. The engine is intended to do half the work of an engine used for a fast train. It weighs 44½ tons, and has drawn, according to the *Electricien*, 147 tons at 28 miles an hour and 100 tons at 62 miles an hour. By the addition of a second motor on each axle, it is stated that it can draw 125 tons at 62 miles an hour. Tests on it have been continued for more than a year, and a most successful trial between Paris and Melun was made a few weeks ago, in the presence of several prominent French railway men.

Electrical Equipment at McGill University, Montreal.—The *Western Electrician* states that Prof. R. B. Owens is engaged in extending the course and adding to the equipment of the electrical department of McGill University. In the laboratory all the machines, instead of being permanently fixed, will now be mounted on testing blocks, so that it will be possible to move them about from place to place, and a special crane for this purpose has been supplied. There are also being constructed a number of testing tables permanently wired up to facilitate experimental work. The number of accumulators has been increased, and a number of high-potential transformers has been added. The wiring for the laboratories will be under the floors and testing blocks, and distributing boards will be used, so that it will be possible to throw any individual laboratory on to any circuit. There has also been provided a number of specially designed electrical speed indicators for extremely accurate measurements of speed. These instruments have been worked out by Prof. Owens himself, and have been constructed to give an instantaneous reading accurate to one-fifth per cent. Alternating-current machines giving one, two and three-phase currents at frequencies varying from a few periods per second to 150 periods per second, a number of two and three-phase induction motors, and a number of transformers for changing two-phase currents into three-phase, have also been installed. It has been decided to establish a standardising laboratory, thoroughly equipped with all necessary primary and secondary standards for electrical and magnetic measurements. A separate laboratory will be equipped for tests and investigation work, and, if possible, arrangements will be effected with manufacturing companies whereby the University will have the use of new types of machines

The Locomotives Act, 1898.—The Locomotives Act, 1898, comes into operation on January 1st next. It applies to the whole of England, and will effect some radical changes in the law relating to the licensing and use of traction engines, steam road rollers, and other locomotives in the public streets. In anticipation of the Act coming into force, says the *Engineer*, suggestions have been submitted to the Local Government Board by the officials of the several County Councils of districts adjoining London with reference to the new bye-laws which will have to be made, and the forms of licences and other forms which will have to be used in consequence of the passing of the Act, and it is anticipated that model bye-laws and forms will be issued by the Local Government Board on the subject. The Act provides that the existing bye-laws shall remain in operation until August 2, 1899, unless previously repealed or suspended by bye-laws made under the new Act. In this connection it may be mentioned that the London County Council is empowered under Section 1 to grant permission for vehicles drawn or propelled by a locomotive on a highway to carry weights in excess of those stated in Section 4 of the Locomotives Act, 1861; and under Section 8 the County Council is authorised to give consent to more than the three vehicles allowed by the new Act being drawn by a locomotive. It is thought probable that applications under those sections may have to be dealt with in London immediately the Act comes into force, and under Section 14 the County Council can act through its surveyor or other authorised officer. As a result of this the London County Council has just decided to permit the Highways Committee to act on its behalf in relation to all matters under the new Act pending the issue of a further order on the subject, and has also authorised Sir Alexander Binnie, the chief engineer, to deal with all applications made to the Council under Sections 1 and 8, already referred to.

Train Lighting by Electricity.—A recent number of the *Electrical World* of New York contains some interesting notes on the subject of the electric lighting of railway trains. After a reference to the system of axle-driven generators and storage batteries, in which automatic means are provided for cutting out the dynamo when it is running below its normal voltage, and for preventing the voltage from assuming too high a value—the latter being frequently done by a slipping belt, as on Stone's system—our contemporary suggests the following as the only known method of obtaining practically constant voltage with high variable speed, and without troublesome devices:—"The use of a dynamo with a flat-topped characteristic with shunt exciting coils of magnetomotive force sufficient at the storage battery voltage to carry the magnetisation well above the bend of the curve, and with field coils in series with the armature tending—when the machine generates current—to oppose the shunt excitation. With such an arrangement small outputs through the series coils would not materially lower the voltage, but in case the speed rises, tending to increase the output, and the excitation falls below the bend of the magnetisation curve, any further increase of the load would materially diminish the field density and, consequently, the voltage. With proper design such a machine could be made to run over a wide range of speed with a small change of output at constant pressure if delivering to a storage battery. The latter would, of course, maintain the stability of voltage otherwise unattainable with shunt machines or under-saturated fields, and would absorb the variations in load necessary to the differential compounding. The series coil, instead of reducing the equilibrium of voltage between the machine and battery, as with ordinary compound generators, would tend, with this reverse action, to increase it. With any system of field density inversely proportional to the speed, the armature reaction with constant load becomes a troublesome factor at the high speeds and consequent weak fields, but there are several well-known methods of obtaining a proper commutation with variable field strength, so that this difficulty is probably not a serious one." *Apropos* of train lighting, we may mention that a number of new carriages, lit on Stone's system, have recently been started on the Metropolitan Railway.

CONTEMPORARY ELECTRICAL SCIENCE.

[Compiled by E. E. Fournier d'Albe.]

Conservation of Matter.—The ultimate test for the existence of matter is its inertia, but all quantitative estimations are practically based upon its weight. Hence, if we wish to test the fundamental law of chemistry, that of the conservation of matter, we investigate whether a substance changes in weight when subjected to a variety of chemical actions. It is *à priori* quite conceivable that it should. Gravitational attraction might be a property primarily attached to the molecule, and not to the atom. A pound of matter might, under special circumstances, lose its gravitation, just as a bar of iron loses its magnetisation at the critical temperature. In 1894, Landolt described an apparent loss of weight occurring in silver when reduced from its salts to the metallic state. A similar apparent loss was reported in the reduction of iodine from iodic acid and hydriodic acid. After repeating the silver experiment without a decisive result, F. Sanford and L. E. Ray also examined the iodine reaction between potassium iodide and ferric chloride, obtaining about 80 grammes of iodine. The results showed not a loss, but a gain of about 0·02mg., that being the four-millionth part of the total weight. That amount is very near the limit of experimental error, and is slightly less than Landolt's loss. If gravitation were a molecular and not an atomic property, a much greater change would have to be expected.

[Sanford and Ray, *Phys. Review*, Nov., 1898.]

Calcium Carbide.—The carbides of potassium and lithium, C_2K_2 and C_2Li_2, may be obtained in transparent and colourless crystalline plates. The aluminium carbide, C_6Al_4, sometimes crystallises in transparent yellow plates. But when Henri Moissan first prepared the carbides of calcium, strontium, and barium he described them as opaque, except in very thin sheets. He now finds that calcium carbide is only made opaque by impurities, chiefly of iron. When it contains no trace of iron, it is as transparent as the lithium carbide or sodium chloride. This may be proved by heating to a dull red a mixture of metallic calcium and pure amorphous carbon derived from the rapid combustion of acetylene. This gives a white carbide decomposed by water with formation of calcium hydrate and acetylene. Under the microscope, the white carbide appears as a mass of transparent crystals. It is a noteworthy fact that the heat of combination of the carbon and the calcium suffices to fuse the carbide, whereas that has never yet been accomplished in the electric furnace. On heating the white carbide with a minute quantity of iron oxide, the reddish-brown appearance of the commercial article is obtained.

[Moissan, *Comptes Rendus*, Dec. 5, 1898.]

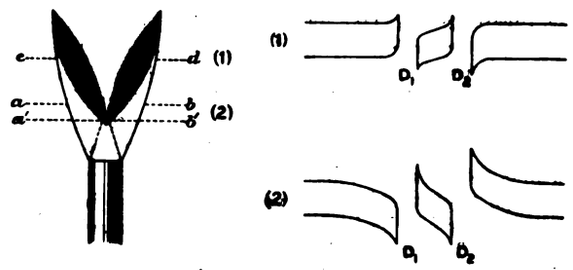
Properties of Aluminium.—Aluminium has long been regarded as a metal capable of resisting most chemical agencies. But A. Ditte has pointed out that if aluminium does not appear to be attacked by air or water, nor by dilute sulphuric or nitric acids, although its heat of combustion of 131 calories places it near calcium, that is solely due to the fact that it immediately covers itself with a layer of hydrogen, nitric oxide, or alumina, which is continuous, impermeable, and very adhesive, and effectually prevents any contact between the metal and the liquid in which it is immersed. When by any chance the protecting layer is removed, chemical action at once sets in, and goes on until the aluminium is completely dissolved. The layer is not proof against the action of acid salts, or common salt in presence of an acid, such as vinegar. Since aluminium compounds have no poisonous effects upon the system no complications as regards health need be feared where aluminium cooking utensils are used, but their rapid wear would render them unfit for military purposes. A 1 per cent. solution of washing soda, so often used for cleaning, attacks aluminium even in the cold.

[Ditte, *Comptes Rendus*, Dec. 5, 1898.]

Absorption in a Magnetic Field.—A. Cotton describes a simplified form of Righi's absorption experiment which places it within the reach of moderate experimental resources. A beam of white light, preferably from an arc lamp, traverses a Nicol with its principal section at 45deg. to the horizon, a strong electromagnet with its lines of force horizontal and at right angles to the beam, and a second Nicol crossed with the first. On introducing into the magnetic field a sodium burner and making the current, the extinction is annulled, and the arc is clearly visible and of a yellow colour. If the first Nicol is turned through 45deg., thus placing its principal section horizontal or vertical, the phenomenon is no longer observed; the extinction once brought about remains, whatever the strength of the magnetic field. Righi, it will be remembered, operated with a field parallel to the beam, and used a circular polariser and analyser. The effect observed by the author is readily explained by the theory of the Zeeman effect. Similar phenomena may be observed on substituting a small vessel containing nitrogen peroxide for the sodium flame. The arc then appears green, that being the complementary colour of the gas. Experiments with didymium sulphate yielded no result.

[Cotton, *Comptes Rendus*, Dec. 5, 1898.]

Anomalous Dispersion of Vapours.—H. Becquerel has already given an explanation of Macaluso and Corbino's discovery of a very high rotatory power of sodium vapour for the rays immediately adjoining the D lines. His explanation was based upon the assumption of an anomalous dispersion, and this he has now succeeded in placing directly in evidence. He made a kind of gaseous prism by the simple expedient of



placing a platinum gutter across the inner cone of the Bunsen burner. The gutter was a sheet of platinum bent into a right angle, and the sodium salt rested in the angle. The two cylindrical lenses shown in the diagram were thus produced. As *a b* and *a' b'* they acted as a prism with its refracting edge below, at *c d* as two prisms with their refracting edges upwards. The spectra observed in the two cases in the neighbourhood of the D lines are shown as observed by means of an auxiliary prism. They conclusively prove anomalous dispersion by the sodium vapours.

[Becquerel, *Comptes Rendus*, Dec. 5, 1898.]

Conductivity and Luminosity of Flames.—A. Smithells, H. M. Dawson, and H. A. Wilson have endeavoured to ascertain whether the luminosity imparted by vaporised salts to flames is related in a definite manner to the electrical conductivity of the salt vapours. Since, according to the electrolytic dissociation theory of Arrhenius as applied to dilute solutions, the metallic ion in virtue of its electric charge can persist in an oxidising medium, it appeared to the authors that if the same theory were really applicable to salts vaporised in flames, it would afford an explanation both of the liberation of the element, and of its persistence in the midst of an oxidising atmosphere of flame gases. It would naturally be expected that the more readily oxidisable the metal is, the less light would it emit in the oxidising portions of the flame. But the results of the experiments show no definite relation between the chemical nature of the electrical conductivity of the base and its coloration or luminosity. The apparatus consisted of an arrangement whereby the two cones constituting a Bunsen burner could be separated widely and maintained apart for any length of time. An electrode system, consisting of two coaxial cylinders of platinum-iridium alloy, was fixed between them. The authors found that the conductivities of the haloid salts of a metal increase with the atomic weight of the halogen, whereas the conductivities of the oxy-salts are approximately equal. No effect is produced upon the conductivity by decolorising the flame by means of chloroform.

[Smithells, Dawson and Wilson, *Proc. Roy. Soc.* for Nov. 17, 1898.]

ELECTRICAL STAGE APPLIANCES AT DRURY LANE THEATRE.

Up to the present the application of mechanical power for working the stage of a theatre has been limited to the use of steam or hydraulic pressure. In this country, as a matter of fact, there has as yet been no application of mechanical power whatsoever, with the exception of some small experimental hydraulic jiggers laid down in Edinburgh in the seventies, some lifts in the Lyric Theatre in the eighties, and then about two years back, at the Drury Lane Theatre, a somewhat more elaborate installation was attempted in the form of two hydraulic "bridges." The application of modern mechanism has been practically reserved for the Continent, and even in the United States little has been done. As far as the Continent is concerned, hydraulic power has primarily been in favour as compared with steam, and some of the larger stages of the opera houses in those countries, have been entirely equipped with hydraulic appliances. But both in installation and maintenance, the hydraulic stage has been found to be very expensive, hence it was necessary to apply some other power. Attention was naturally at once directed to electricity, and some slight attempts have already been made in Munich to use electrical power in moving the big "turntable" or the so-called "turntable stage." But it has been fortunately left to this country and to the metropolis to apply electricity for stage purposes on a really large scale, and also in a manner that is novel as compared with continental work. It is at the historic old Drury Lane Theatre that this example has been set, and it is here that on Boxing Night last the floor of the stage was for the first public performance moved with electric motors worked in a very economic manner from the ordinary lighting mains.

The work of remodelling the Drury-lane stage has been entrusted to Mr. Edwin O. Sachs, the architect, who for some considerable time has been zealously advocating the application of electricity to the stage, and whose work, entitled "Stage Construction," was recently referred to in these columns. He had the good fortune of holding the commission from Mr Arthur Collins, a manager who believes in the more modern equipment of the theatre, and he has further had invaluable assistance from the Thames Ironworks and Shipbuilding Co., who, whilst acting as contractors, dealt with this experimental order in a manner that should elicit admiration. The present phase of the work entrusted to Mr. Sachs relates primarily to the movability of the stage floor, and he has divided this floor into six large sections. Of these two are the older hydraulic installation, whilst two others include the electrical installation just completed. The remainder will be taken in hand shortly on similar lines, and the hydraulic plant may also be transformed into an electrical one in the near future.

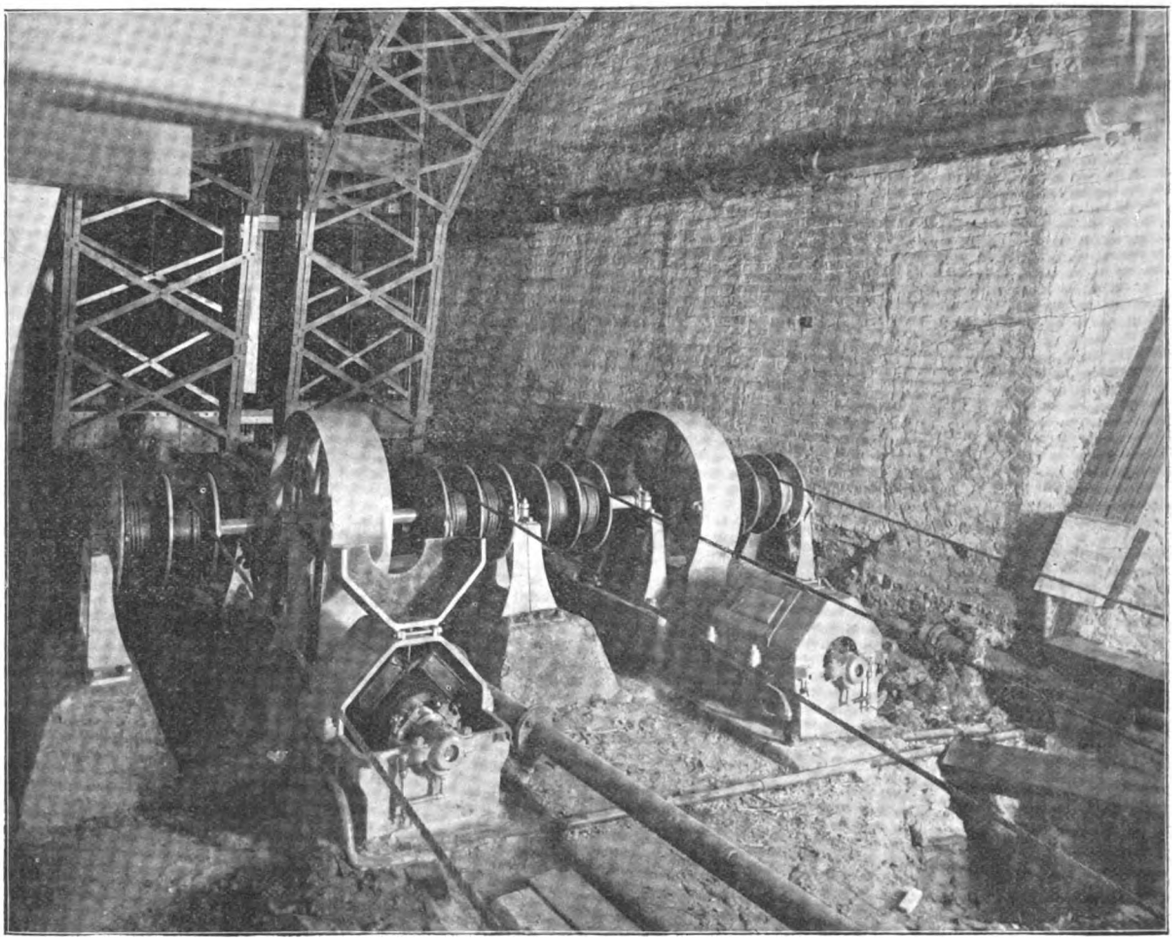

FIG. 2.—Electrically-Operated Hoisting Gear for the Moveable Sections of the Stage at Drury-lane Theatre.

It is not, however, with the stage as a whole, nor even with the stage floor as a whole, that we wish to deal at the moment. The point of interest for us lies in the new electrical plant and its possibilities. This plant, as just completed, practically takes the form of two gigantic lifts (Fig. 1), which rise above the stage or sink below it, and have to be very carefully balanced, so as to travel smoothly, absolutely noiselessly, and with a great factor of safety. The work for which they are principally intended is the rapid change of stage floor level, either with the view of forming terraces, or similar features in the mounting of a play, and, of course, the changes will frequently take place with the curtain up, as for so-called transformation scenes. They are to obviate the former endless building-up, which requires a large staff of men, and is always dangerous and unsatisfactory, and which, further, precludes any such movement as indicated with the curtain up. The load that any one section will probably carry is that of a crowd of 30 or 40 actors, with an ordinary load of scenery; but the contingency of coaches, horses, &c., travelling over

Digitized by Google

the lifts had to be considered, for, with the ever-increasing spectacular effects, there seems no limit to the strains which mechanism at Drury Lane would have to meet.

Mr. Sachs' principle for obtaining the desired results might be shortly expressed as that of a railway bridge suspended from cables and travelling in guides, the cables being wound

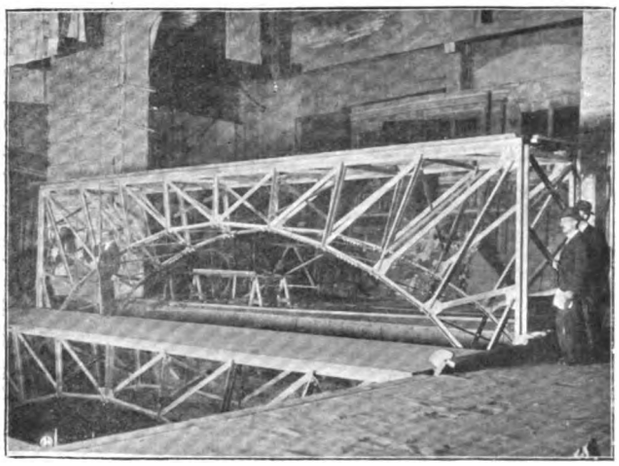

FIG. 1.—Two Electrically-Operated Sections of the Stage Floor at Drury-lane Theatre. One section is shown at the stage level, the other 10ft. higher.

round "drums" and worked by electric motors (Fig. 2). The dead weight of such a bridge has to be partially taken by counterweights, and provision made for working the whole appliance by hand should the current fail. Each section, measuring 40ft. by 8ft., comprises two light steel arched lattice girders of simple but substantial design, 38ft. 10in. in length, spaced 5ft. 6in. apart, and well braced together to form one rigid structure, on the top of which the flooring forming part of the stage is fixed. The steel portion of each lift weighs a little over $4\frac{3}{4}$ tons; the wooden platform which forms part of the stage floor, together with the joists on which it rests, weigh about $1\frac{1}{2}$ tons more, the total weight lying between 6 and $6\frac{1}{2}$ tons. From 4 to $4\frac{1}{2}$ tons of this total weight is counterbalanced. The elevators have been designed to travel from the mezzanine floor, situated 8ft. 6in. below the stage, to a height of 10ft. 6in. above the stage; and to ensure smoothness and silence in working, with freedom from "binding," the ends or legs of the girders have been made of a considerable depth, sliding in angle guides attached to steel stanchions. The mechanism which elevates the lifts is placed entirely below them (Fig. 3), in order to allow a clear, uninterrupted floor when the top of the lifts are "flush" at ordinary stage level. Each lift has a totally independent and complete set of mechanism to work it. Power is supplied from the electric mains to a four-pole enclosed shunt-wound motor, which develops $7\frac{1}{2}$ H P. at 520 revolutions per minute, but is capable of working at higher rates on emergencies. The speed is reduced in the ratio of 104 to 1, through a large worm-gear, the worm-wheel being geared to a shaft which carries two winding drums making five revolutions per minute. Upon these drums are wound steel wire ropes, which pass over guide pulleys and are connected at four places to the legs of the lift—one near each corner. The speed of lifting corresponding to the full speed of the motor is 16ft. per minute, which, however, can be reduced through resistances in circuit with the motor to 6ft. per minute. Compensating arrangements equalise the tension in the ropes, so that the pull is quite steady and uniform. The movement of the lift is controlled by a combined starting and reversing switch, which is operated by a man at a station below the stage level, and so placed that he can see the elevators. The operation of changing from "power" to "hand" working, or *vice versa*, takes but a few seconds. On the end of the worm shaft opposite to the motor is keyed a spur wheel, a similar wheel keyed upon a double hand like an ordinary crab being arranged to slide into or out of gear with it.

These notes will not be complete without duly allotting the credit of certain features in this installation. Mr. Grove, of the Thames Ironworks Co., had charge of everything relating to the electrical part and designed the motors, as well as the minor electrical appliances. The combination of the motor, winding gear and "crab," which is particularly ingenious, particularly well suits its purpose, and there were, of course, numerous difficulties to contend with to obtain what was desired. The execution of the contract generally, and primarily everything relating to the constructional work, was in the hands of Mr. Alexander Stuart, of the same firm.

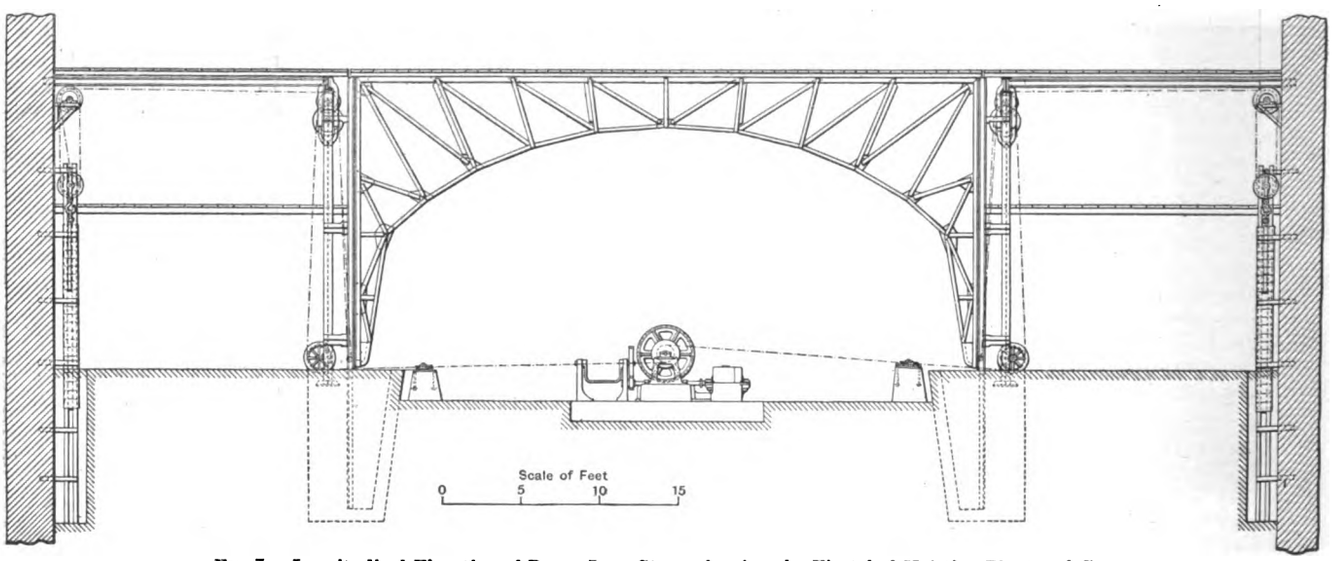

FIG. 3.—Longitudinal Elevation of Drury Lane Stage, showing the Electrical Hoisting Plant and Gear.

India-Rubber Culture.—The *Elektrotechnische Zeitschrift* is informed that an expedition is being equipped which will proceed to the German colonies in West Africa to introduce rational methods of rubber culture. The expedition will first investigate the botanical conditions for a suitable cultivation and utilisation of the plantations, and profit by the experiences of foreign colonies to the advantage of those within the German sphere of influence. It is intended to transplant the wild rubber plants and cultivate them on a large scale in plantations. At the same time investigations will be made as to the relative suitability of the various separation processes to the West African rubbers.

ELECTRICAL INSTALLATION AT THE KENNINGTON THEATRE.

An interesting electrical installation was put in operation for the first time at the opening of the new Princess of Wales Theatre at Kennington on Boxing Night. This installation has been carried out by Messrs. Owen Lucas and Pyke, to whom we are indebted for the following particulars :—

The steam plant includes a Babcock and Wilcox boiler, which had to be specially designed to fit into the small engine and boiler space at disposal. This boiler is capable of working a 112 H.P. engine; it works at 150lb. pressure, and has a heating surface of 1,010 sq. ft. The water is supplied to the boiler by means of a feed pump, or, as an alternative, an injector, direct from the main, a provisional tank being provided to hold sufficient water for two performances. A feed water heater is provided to raise its temperature to 212°F. Owing to the engine room being below the level of the main drain a special sump tank has been provided to carry all the waste water, &c., it being emptied into a drain trap on a higher level by means of an ejector worked from the boiler. The engine is a compound vertical Willans three-crank engine, with combination bed, coupled direct to a Johnson and Phillips dynamo, compound wound for 75 kilowatts. A battery of E.P.S. accumulators, consisting of 56 115 kilowatt S. type cells, has been erected in a specially-designed battery room, nearly 60ft. long. These cells were delivered and erected by the Company in the exceedingly short space of five days. They have an output of 480 amperes for five hours, and in case of breakdown of the plant are more than capable of supplying light to the theatre for one performance on all ordinary occasions.

The engine-room board has been designed to give great facilities in regulation and equalising of the load. The following circuits are run direct back to this board, and are provided with two-way double-pole switches :—

Auditorium (*b*)	carrying	100	amperes.
Auditorium (*c*)	,,	100	,,
Auditorium (stage)	,,	100	,,
Stage main	,,	750	,,
Dressing room	,,	50	,,
Stage projectors	,,	400	,,
Open main	,,	150	,,
Supplementary service	,,	500	,,
Arc lamps	,,	170	,,

The dynamo and cells are provided with automatic current alarms and indicators, so that immediately the current rises above a certain percentage of the maximum safe load notice is given to the engineer, and he can, by means of these two-way switches, throw off any circuit on to the cells, thus relieving the plant, so that in case of necessity the whole current from the dynamo and the cells can be taken at the same time, giving an available output of over 120 kilowatts. The board is provided with a complete set of indicating and recording instruments. The accumulator charge and discharge switch consists of two sets of contacts mounted horizontally, the connecting arms travelling between them by means of worm gear, the first 10 cells (positive end) being used as regulators. The circuit mains from the board run to the various distribution boards throughout the building in earthenware conduits, provided with brick chambers and draw boxes.

The stage board has been specially designed to give an exceptionally complete control with as few movements as possible. The colour lighting is operated from a board so designed that master switches are rendered unnecessary, the colours being arranged in horizontal lines, two of these switches in each line being linked together in such a way that they can be operated independently or the whole together by the movement of a main lever. The colour plugs on the stage and auditorium lights are controlled by similar means. Special resistance switches have been supplied on a similar principle and have been designed to occupy as little space as possible. Each of these resistance switches can be operated independently or the whole of those belonging to one colour simultaneously by means of a main lever. The resistances consist of platinoid wire coils mounted on slate frames, a special resistance room, with fire-proof lining and ventilating shafts being built to contain them. The pay office and sub-distribution boards are of the porcelain bridge fuse type, each circuit carrying five amperes and being provided with a single pole switch. The stage board, pay office and sub-distribution boards were manufactured by the Edison and Swan Co., and the engine room board by Messrs. Barclay (the main contractors), who have satisfactorily carried out the whole of the wiring.

The wiring system throughout, beyond the main boards, is contained in iron barrel, there being no right angle bends in the building, all tappings and bends being made through the iron draw-boxes. The system is completely watertight, and it is possible by means of these draw boxes to withdraw any length of cable in the building for examination and repairs. Artistic fittings have been supplied by Messrs. Barclay, the Edison and Swan Co. and others. The exits of the theatre are illuminated by eight double-carbon Brockie-Pell arc lamps, worked two in series. There is in addition a powerful search-light mounted on the roof. The total number of lights installed, exclusive of plugs and plug board connections, is over 2,000.

THE COMMERCIAL AND BUSINESS ASPECTS OF MUNICIPAL ELECTRICAL SUPPLY.

BY ALFRED H. GIBBINGS, M.I.E.E.

(*Concluded from page 269.*)

Fitting Up and Managing a Corporation Show room.

A show-room for the purpose primarily of exhibiting and explaining the apparatus and other articles which are supplied to the public will always be found to be an exceedingly useful, if not an absolutely necessary, adjunct to the ordinary works and clerical departments of a municipal electricity undertaking. During the first year of such a business, when the department will probably be fully occupied in connecting to the supply mains a heavy rush of applicants, and in providing a proper complement of machinery, mains and meters, the subsidiary matters already dealt with in these articles may have to be postponed, and no necessity for a show-room would then exist. In the course of the second or third year, however, it will probably be found advisable, because advantageous, to "start" a show-room, the purposes of which will be entirely distinct from those of either the works or clerical departments.

The show-room section should be constituted and arranged to entirely relieve, if possible, the general clerical staff of the casual and extraneous, though no less important work, which would otherwise fall upon it. It should, first of all, perhaps, be an office of general inquiry. By natural sequence it would thus become the medium for imparting information gratuitously to the public on all matters relating to the business of the whole department and the apparatus used. Such a medium may be said to be a recognised necessity. Every municipal electrical engineer knows how many and varied are the inquiries made by consumers and prospective consumers with reference to installation work, fittings and electrical apparatus generally, of which, in the majority of instances, they have no knowledge whatever. It is this want of knowledge which is often taken advantage of by the unscrupulous wiring contractor, and hence in the protection of their own interests, as well as in the interests of the consumer, stringent wiring regulations are, or should be, laid down by the Corporation. Judging superficially, and they can judge in no other way, the public very often consider these regulations unnecessarily severe. There can be no doubt that a little explanation would throw great light on the subject, and the apparent unreasonableness of certain conditions and requirements to be observed in wiring work would soon disappear. The most appropriate means for such a desirable purpose is afforded by instituting a show-room to deal *inter alia* with this matter, and the discharge of this duty should form one of its principal features. It is far, otherwise when such matters are left to take care of themselves, or at best are left entirely to the clerical staff. As the old wise saying has it, "What is everybody's business is nobody's business," and in that case

Digitized by Google

inquiries are apt to be treated as no part of the business at all, and answers are given usually in a very perfunctory way. The tendency and temptation to give indifferent and incomplete information is almost sure to exist. At all events the same satisfaction is not likely to be given as if the duty devolved expressly upon one official, specially engaged for the purpose.

The staff of a show-room need not be an expensive item; one man, with the possible addition of an errand boy, will be found amply sufficient in most cases. This very modest equipment has met the requirements of gas companies' show-rooms for the hire of gas stoves, &c., in cases where the customers number many thousands. A great deal depends, however, upon the selection of the man for such a post. Anybody will not do. He should be, of course, specially qualified in a technical sense, and also be of an obliging and courteous disposition. It is advisable that the show-room should be located in a convenient, easily accessible, and, if possible, central position of the town. A shop front, where articles could be exhibited with, say, one or two working models of motors, would possess a double advantage; the premises would be attractive, and their locality would soon become well known. When a portion of the electricity works or the town hall office is set aside for the purpose, much of the usefulness of the show-room will, of course, be lost. The former is usually too far out of the town for many persons to reach, and the latter is not likely to offer the same attractions to the public as a shop.

In addition to the function which it has just been suggested should be the characteristic feature of the show-room, there are other ends it may well subserve. But the further scope will, of course, depend upon local circumstances and the extent to which the electricity committee considers it advisable to enlarge their enterprising borders. Where the Corporation themselves contract for installation work, or a hiring out department exists, much of the clerical work can be allocated to the show-room. The books of these departments, the nature and method of keeping which have been explained under the head of *Equipment and Management* and *Hiring-Out of Motors, Arc Lamps and other Apparatus* should be kept by the show-room staff, which, of course, would have to be augmented for this special and superadded work. In such cases it could be arranged that the payment of small accounts, such as for motor oil, carbon brushes, arc lamp carbons, &c., and the rental for apparatus on hire, should be received at the show-room at the time of making the purchase or applying for goods on hire. This would save considerable time and work by superceding the usual routine of making out formal accounts, which have to be paid at the collector's office at the Town Hall or elsewhere, to say nothing of avoiding bad debts and relieving the consumer from much trouble.

We have thus dealt with the show-room, considered specifically as a general inquiry office. Let us now proceed to look at it in the aspect of a show-room, taking the term in its usual significance. The articles on exhibition should include heating and cooking apparatus, of which the radiator has hitherto been the most popular; electric motors fitted up in sizes varying from ½ H.P. to 10 H.P.; electric fans and forms of ventilating apparatus; samples of material used in wiring work, showing the quality and design required by the Corporation; printed matter relating to every branch of the undertaking; apparatus, if any, used in the method of charging for electricity supplied, such as demand indicators, time switches, &c.; types of arc lamps, such as open, enclosed and double-carbon and incandescent lamps, showing classes of terminals, methods of frosting and efficiencies of different candle-powers for varying situations.

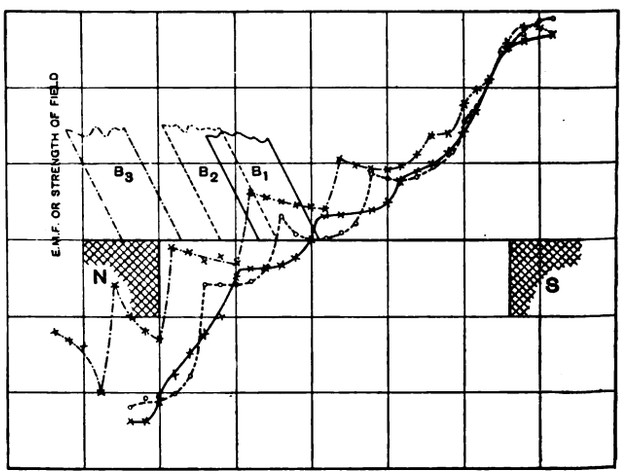
Some municipalities who do not care to undertake the sale of goods enter into an arrangement with different firms to exhibit their goods, referring purchasers to the firms direct, but charging a small commission on transactions. A list is then kept at the show-room, giving prices and approximate current consumption of each article.

It is almost unnecessary to add to what has already been suggested the necessity of having a supply of electricity for show-room requirements. If the system is low tension continuous current with three wires, then the three wires should be brought into the premises. If, however, the system is alternating current, then it will be advisable to keep at hand transformers for varying voltages. Suitable switchboards should be arranged on one or more sides of the room, with cut-outs on both poles, and a series of terminals for branch circuits to be readily connected to any apparatus. Each of these branch circuit terminals should also have double-pole fuses. There should also be ample floor space. Not that a large supply of stock should be stored in these premises. It should not, indeed, be necessary to keep at the show-room more than a sample or two of each kind of apparatus. Space is a desideratum rather because of the necessity which will frequently arise of setting out individual items of stock for inspection and examination. The stock proper should be kept at the works stores, as the storekeeper should be responsible for all goods received into the department, no matter to what particular branch they are ultimately allocated.

THE EFFECT OF COMMUTATION ON THE FIELD OF DYNAMOS AND MOTORS.

BY W. H. EVERETT, B.A., B.E., AND A. H. PEAKE.

In a previous article* we described some experiments on the character of the change of current in an armature coil of a dynamo and motor respectively while that coil is passing under either brush. We now give an account of an investigation as to the effect of this change of current on the field. The experiments were carried out with the two-pole 5 kilowatt Crompton machine previously used. An exploring coil of 10 turns of fine wire was wound on one of the armature coils,



Full line curve, 2·2 amperes. Dotted line curve, 8 amperes. Chain-dotted line curve, 27 amperes.

FIG. 1.—Motor Curves with Thin Brush.

one end being connected to a slip-ring and the other to a revolving adjustable contact-maker. In this way the E.M.F. generated in the coil at any instant could be found by charging a condenser with this E.M.F. and then discharging at will through a ballistic galvanometer. Each armature coil consisted of two layers of three turns each, and the exploring coil was wound between the middle and rear conductors of the upper layer.

In the figures given below, abscissæ show the relative positions of the centre of the armature coil on which the exploring coil was wound, the pole-tips (N, S) and the brush (B), the intercept between successive ordinates representing the width of one coil; and ordinates represent the E.M.F. induced in the exploring coil. A change in the speed of the machine merely produced a proportionate change in the deflections of the galvanometer, so that for the sake of com-

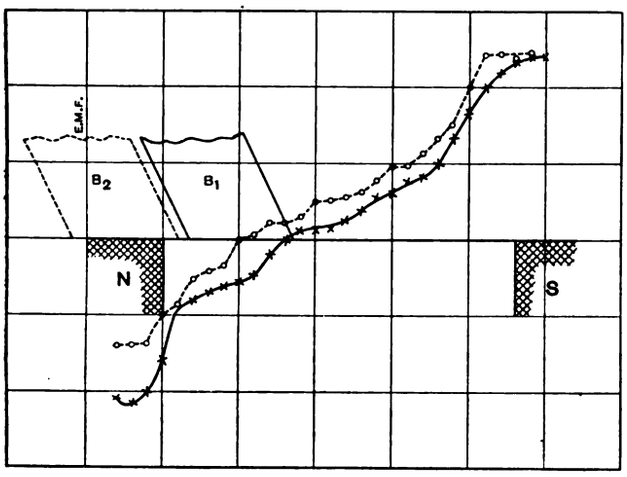
* See *The Electrician* April 22, 1898, p. 861.

Digitized by Google

parison the vertical scale is made inversely proportional to the speed in each case.

Three different brushes were successively used. The first was that described in the previous article, being divided into two parts connected by a low resistance, and giving E.M.F. curves under the same conditions as for the current curves previously obtained. The second was an ordinary brush, but of the same thickness only as the first. The third was an ordinary brush of sufficient thickness to cover about one segment and a third.

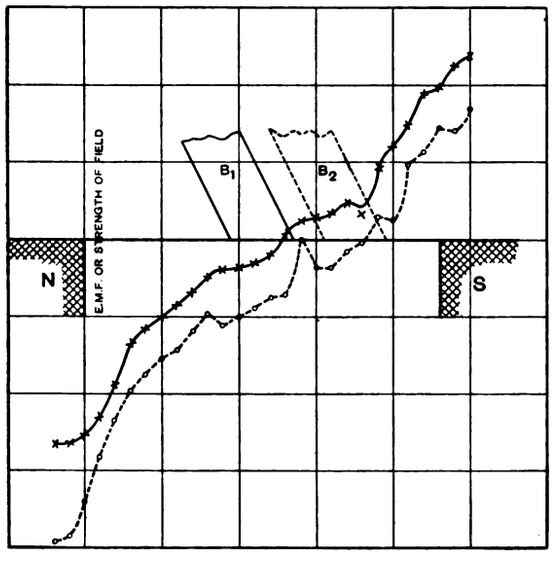
Broadly speaking, the curves show that the E.M.F. decreases from its initial negative value under the trailing horn,



Full line curve, 2·3 amperes. Dotted line curve, 26 amperes.

FIG. 2.—Motor Curves with Ordinary Brush.

rapidly at first, then more gradually, to zero; and then increases, slowly at first, and afterwards more rapidly, to its final value. The general shape of the curve is, of course, due to the distribution of the main field. The relative flux densities under the pole-tips are shown by the heights of the first and last ordinates of the curve, but the examination of the field was not carried beyond these points. The greatest



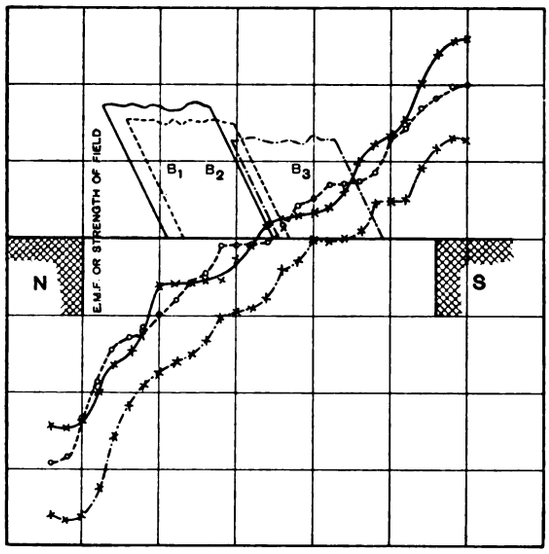
Full line curve, 7 amperes. Dotted line curve, 35 amperes.

FIG. 3.—Dynamo Curves with Thin Brush.

ordinate in the curves represents an E.M.F. generated in the armature coil of about half a volt when the total E.M.F. of the machine is 30 volts. The field is found to be affected by the change of current in the coil under the brush, and this effect is repeated at regular intervals corresponding to the distance between the centres of adjacent coils. The presence of this effect is clearly shown in the curves, causing successive ripples, of which the one under the brush is, as we should expect, the most marked. A decrease in the positive, or an increase in the negative, current in a coil causes a positive induced E.M.F. in that coil, and *vice versâ*; therefore, comparing these ripples with the curves of current change shown in the former article, a descent in the current curve should correspond to a positive distortion or excessive rise in the E.M.F. curve, and an ascent in the current curve to a depression in the E.M.F. curve. In some of the curves it will be seen that there is an indication of this correspondence.

When the brush was not in the correct position to avoid sparking, sudden sharp deflections were found to occur in the curves at points where the segments of the commutator leave the toe of the brush. These deflections are downward when the brush is too far backward, and upward when it is too far forward, as would be expected from the change (due to contact resistance) of the current in the coil leaving the brush.

When the thin brush is used (*see* Figs. 1 and 3), the ripples, in both dynamo and motor curves, are much more pronounced with heavy than with light loads, since the current change is greater. Again, the difference between the dynamo curves, at various loads, is not nearly so great as between the motor curves; moreover, in the case of the dynamo the curves are smoother than in the case of the motor. These results are probably both due to the same cause, namely, that the current and E.M.F. in the coils under the brush are changing in the same direction in a dynamo, but in opposite



Full line curve, 3 amperes. Dotted line curve, 18 amperes. Chain-dotted line curve, 35 amperes.

FIG. 4.—Dynamo Curves with Ordinary Brush.

directions in a motor. In comparing curves for different loads it should be borne in mind that the brush does not remain in the same position, being always adjusted to avoid sparking; this accounts for the crossing and recrossing of some of the curves.

Experiment shows that there is no appreciable difference produced in the character of the curves by exchanging the split brush for an ordinary one of the same thickness; accordingly none of the solid thin brush curves have been included in the figures. With the thicker brush the curves are comparatively smooth in all cases; this, of course, is chiefly noticeable in the heavy load curves, since they were originally the most rippled. The reason for this smoothing effect is, presumably, that whenever one coil has just come under the brush, or is just leaving it, there is an adjacent coil also short-circuited, which acts like the closed secondary of a transformer, and thus partly counteracts the self-induction of the first coil. Hence any sudden change of current in one of the shorted coils has a less effect on the main field, since its influence is counteracted by a corresponding change in the adjacent coil. The field, therefore, is steadier and the E.M.F. curve smoother with the thicker brush.

TELEGRAPHY BY MAGNETIC INDUCTION.*

BY S. EVERSHED.

Although many practical trials of telegraphy by means of the mutual induction between two distant circuits have been made during the past ten years, this form of wireless telegraphy has of late been rather overshadowed by the more brilliant possibilities of telegraphy by means of Hertzian waves of high frequency, and the low-frequency electromagnetic system has hardly received the attention it deserves. It is probably not capable of such general application as Hertzian telegraphy, but it has a distinct advantage in employing electromagnetic waves of low frequency, the laws of which are simple and well understood, and the necessary apparatus for transmitting and receiving will not be too remote in type from dynamos and motors to enable us to readily understand the principles on which their design and workingshould be based. Moreover, with one limitation, to which reference will afterwards be made, our knowledge of the laws of magnetic induction is sufficient to enable us to determire precisely what conditions are requisite for communication with a place at any distance.

The author's attention was directed to the subject some years ago in connection with communication between light-vessels and the shore, and his magnetic induction telegraph was, as is pretty generally known, tried between the North Sand Head light-vessel and Dumpton Gap, and proved a total failure, owing to the almost complete absorption of the electro-magnetic waves by the media through which they were required to pass. During the time these trials were in preparation exhaustive experiments were carried out at Woodfield Works by the author, in conjunction with Mr. Oswald Cox, and the main principles of telegraphy by magnetic induction were investigated, and one or two fundamental formulæ worked out. It will not be inappropriate at the present time, when wireless telegraphy is coming into prominence, to put the conditions then arrived at before the members of the Institution as briefly as possible.

When we desire to convey energy through space from one place to another by electro-magnetic waves, we must provide a primary circuit at one place to emit the induction waves, and a secondary circuit at the other place to receive them. Every time a current is varied in any way in the primary a certain fraction of the energy linked with this circuit will appear in the secondary, to run down there into heat (as C^2R), unless there is a motor or other translational device included in the secondary. By maintaining an alternate current in the primary a continuous supply of energy is available in the secondary, and a suitable indicator in the secondary —that is to say, a motor adapted to convert part of the received electrical energy into energy of motion, either visible or audible— will enable the receipt of the energy to be detected. Break up the primary current into dots and dashes and you have a working telegraph. Of course there are other means of indication which are not in any ordinary sense motors. For example, electrolytic effects may give a direct indication of the secondary current, or a coherer may be used to give indirect indication by closing a local circuit. But the principles underlying the application of magnetic induction to wireless telegraphy will be better understood if we assume the indicating device to convert some part of the received energy into motion. It may be motion only capable of bringing two contacts together to close a local circuit, or capable of making audible sound waves in the air, or it may be directly visible; but in any case something is made to move; and the moving body being, presumably, attached to some support, either by pivots or an elastic suspension, cannot be moved without the expenditure of energy to overcome the mechanical friction of the pivots or the molecular friction of the suspension. If sound waves are set up there is a further expenditure of energy.

The secondary current being, of course, an alternating one, it is probable that the motion imparted to the indicating device will be oscillatory also. The ordinary Bell telephone will occur to everyone as typical of such an indicating device. The friction—resistance to motion—may follow any law with regard to velocity, it may even be constant (independent of velocity), but in every case examined by the author the frictional resistance has proved to be simply proportional to the velocity—at all events, at such frequencies as are likely to be used in practice. In what follows it will be assumed that when moving with velocity v, the moving body requires a force equal to rv to overcome friction, r being a constant for any particular moving system. Calling the amplitude of oscillation a, and if $p=2\pi F$, the mean power required to oscillate the moving part will be $=\frac{1}{2}ra^2p^2$, and at its maximum value the power spent in overcoming friction will be ra^2p^2, the oscillation being a simple sine function.

Having got an indicator, the first step towards it application to an induction telegraph must be to determine the value of the coefficient r, and to decide upon a value for the amplitude a, which will give indications of the necessary magnitude. These two data will enable primary and secondary circuits to be designed to give the required secondary power with any given primary power.

The Inductive Circuits.

There are two practicable ways of building such circuits. The first consists of running a pole line of sufficient length at each end of, and at right angles to, the imaginary line joining the two points between which communication is to be established. Each pole line being earthed at both ends, the circuits complete themselves through the earth, and form two circuits in parallel vertical planes. This is the system devised by Mr. W. H. Preece. It was in practical use long before any other system of wireless telegraphy was heard of, and, indeed, it is very largely due to Mr. Preece's early and continuous work in this connection that we have any wireless telegraphy to discuss to-day. The efficiency of this system, taking cost of materials as a measure of efficiency, depends on the average depth at which the current travels in returning through the earth from one earth pole to the other. Many experiments have been made by the Post Office authorities to determine the mean depth of the return path, but the author understands that the results do not indicate any definite law governing the relation between length of pole line and depth of return. In these circumstances it becomes impossible to accurately forecast what any proposed pair of lines will do. Moreover, leakage from one circuit to the other complicates matters.

The other method of forming the primary and secondary circuits consists in running a pole line completely round the boundary of a sufficient area of ground at each station. This, in effect, turns Mr. Preece's two vertical circuits into two horizontal circuits, and there is the immediate loss of one-half the mutual induction between them—an effect only compensated for if the area of the horizontal circuits can be increased. If the areas of the primary and secondary circuits are A_p and A_s respectively, and the distance between them is D (D being large compared with the diameters of the circuits), then the total induction threading the secondary,

$$B=\frac{2\,A_p\,A_s\,C}{D^3}, \qquad \ldots\ldots\ldots \quad (1)$$

when the circuits are in parallel planes normal to the line joining their centres; while in the case of the two circuits lying in the same plane,

$$B=\frac{A\;A_s\,C}{D^3}. \qquad \ldots\ldots\ldots \quad (2)$$

Another point to bear in mind when comparing the vertical and horizontal systems is that in the former a pole line is only used over half the whole length of circuit, the remainder being made up by the earth return. In the latter the pole line extends right round the circuit, and is on that account likely to prove more costly. However, horizontal circuits possess compensating advantages which may easily outweigh their drawbacks, and in the following formulæ for determining the volume of copper in the lines, areas of circuits and primary power required for signalling over any given distance, the circuits are supposed to be laid in a horizontal plane.

The expressions given in (1) and (2) show that circular circuits will give the maximum effect for a given length of pole line. But this is an ideal form which could hardly be contemplated in practice, and it will, therefore, be assumed that each circuit forms the boundary of a square area. Since each circuit will have to serve for both transmitting and receiving, it is clear that they must, if possible, be identical in size and shape.

Let

V_p, N_p, R_p	be the total volume of wire, number of turns, and resistance of the primary circuit.
V_s, N_s, R_s	the corresponding values for the secondary circuit.
a	sectional area of line wire.
ρ	specific resistance of line wire.
s	length of side of square circuit.
D	distance from centre of primary to centre of secondary.
C_p	value of primary current.
W_p	value of power spent in primary.
W_s	total electrical power in secondary.
B	total magnetic induction threading secondary.
E_s	impressed E.M.F. in secondary.
C_s	current in secondary.
M	mechanical power of indicator or motor in secondary.

All the cyclic quantities are assumed to be simple sine functions, and the letters denoting them stand for their maximum (crest of wave) values.

The whole of the power required in the primary circuit is assumed to be that wasted in heating the wires. To be strictly accurate, the power radiated into space, of which a minute fraction appears in the secondary, should be added; but at the low frequencies suitable for working the whole radiated power is very small compared with $C^2_p R_p$. To get the greatest possible conversion into mechanical energy in the secondary E_s must be in step with C_s, and the condition for maximum activity of a motor must be fulfilled. As is well known, this condition requires the back E.M.F. of the motor to be equal to one-half the impressed E M.F. The highest possible value for the mechanical power of the secondary indicator is, there-

* Paper read before the Institution of Electrical Engineers, Dec. 22, 1898.

Digitized by Google

fore, $$M = \tfrac{1}{2} E_s C_s.$$

But $$C_s = \frac{E_s}{2R_s}\ ;\ \text{so that}\ M = \frac{E_s^2}{4R_s}.$$

Now $$E_s = pB = \frac{ps^4 N_s N_p C_p}{D^3}\ ;\ \text{and since}\ C_p = \sqrt{\frac{W_p}{R_p}},$$

$$R_p = \frac{4\rho s N_p}{a},\ \text{and}\ a = \frac{V_p}{4sN_p},\ \text{we have—}$$

$$E_s^2 = \frac{p^2 s^6 N_s^2 W_p V_p}{16 D^6 \rho} \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

also, $$R_s = \frac{16\rho s^2 N_s^2}{V_s}\ ;$$

so that, finally,

$$M = \frac{E_s^2}{4R_s} = \frac{p^2 s^4 W_p V_p V_s}{16^2 D^6 \rho^2}. \quad . \quad . \quad . \quad . \quad . \quad (4)$$

Here we have an expression for the power turned into audible, visible, or in any other way discoverable motion by an indicator considered as a motor—a motor which is only required to overcome its own mechanical friction, and working under the ideal conditions of maximum activity, negligible, electrical resistance and self-inductance, E.M.F. and current in step, and, lastly, *absence of any medium which can absorb* or distort the magnetic waves on their road between the two circuits. As might have been anticipated, the mechanical power does not depend in any way on the number of turns of wire into which V_p and V_s may be divided. The number of turns in primary and secondary will depend only on the E.M.F. of primary generator, and E.M.F. for which the motor is designed; these are questions entirely distinct from the mechanical work to be done, just as the bearing friction in an ordinary motor is quite independent of the volts and amperes of the machine. Formula (4) also indicates that the least volume of wire will be used if we make $V_p = V_s$; and in that case, if we put V_t for the total volume of wire used in the construction of the two circuits, (4) becomes

$$M = \frac{p^2 s^4 W_p V_t^2}{32^2 D^6 \rho^2}. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4A)$$

At this point it will be useful, by working out an example, to give an idea of the mechanical power which can be delivered at a distance of several miles by the expenditure of a reasonable amount of power in the primary circuit, and by means of a practicable weight of wire. Suppose we put 1,000 kilogrammes (about 1 ton) of copper wire into circuits, 1,000 metres square and 10 kilometres apart. Let the frequency be 100 $\sim$, and the mean power spent in the primary circuit be 100 watts. That is to say,

$$p = 628,\ s = 10^5 \text{cm.},\ W_p = 200 \times 10^7 \text{ ergs per second},$$

$$V_t = \frac{10^6}{8{\cdot}9} = 1{\cdot}1 \times 10^5 \text{ c.c.},\ \rho = 1{\cdot}7 \times 10^3 \text{ C.G.S. units},$$

and $$D = 10^6 \text{cm.}$$

If these values are put into (4A), we get

$$M = 0{\cdot}34 \text{ ergs per second.}$$

Now, as will presently appear, it is quite easy to obtain indicating instruments which will work with less than one-third of an erg per second; but it must not be forgotten that the value just given for the mechanical power available is under ideal conditions that can only be approached—never reached.

Transmitting Devices.

It is not necessary to discuss in any detail the apparatus required for producing the alternate or interrupted current in the primary circuit. An interrupted current may be derived from batteries by means of a rotary contact wheel driven by clockwork or by an electro-motor. For telegraphing over great distances the primary power must be considerable, and it will probably prove more economical and convenient to have a small alternator driven by an oil or gas engine. No particular difficulty is likely to be met with in designing a compact plant for the purpose.

Receiving Devices.

In every instance, so far as the author is aware, in which communication has been carried on by magnetic induction or by earth leakage, the ordinary Bell telephone has been used as a "sounder." It is well adapted for the purpose, as it enables exceedingly minute currents to be detected. This sensitiveness does not arise so much from the efficiency of the telephone as a current-detector as from the marvellous delicacy of the human ear, which is able to distinguish sound waves produced by motions so exceedingly small as to be absolutely invisible, even when magnified many times. In the course of the investigation already referred to the author made careful measurements of the magnetic and electrical quantities involved in the telephone, but up to the present he has been unable to devise adequate means for measuring what fraction of the electrical power supplied is converted into mechanical power. This conversion can be estimated for any given amplitude of the diaphragm from a knowledge of the change in induction threading the coils for different displacements of the diaphragm; obtaining in this way the back E.M.F. But the difficulty remains of determining the amplitude when an alternate current is flowing in the coils.

However, in the case of the telephone it is not essential to know the mechanical power in order to ascertain the conditions for working to a given distance. By measuring the alternate current required to produce readable signals it is possible to deduce with fair accuracy the distance over which Morse code signals can be sent. The author has measured the current flowing in a Post Office pattern Gower-Bell telephone while receiving Morse signals readable by a skilled operator in a quiet room—"readable" implying that the message could be read without difficulty. Two operators were found to agree very closely in their estimate, and it appeared that the current for readable signalling was nearly twice the minimum current which produced an audible sound. The current was determined by connecting the telephone to a circular ring of wire through which a measured induction was alternating. The resistance and self-induction of the telephone were separately determined, and the whole impedance was sufficiently large to enable the current to be estimated without reference to the back E.M F. of the vibrating diaphragm. The mean of several observations gave for the maximum (crest of wave) value of the readable current.

$$C = \frac{2{\cdot}9}{10^6} \text{ amperes.}$$

A current of one-half the above value makes a just audible sound.

When a telephone of this type is used as receiver on the secondary of an induction telegraph, the only condition to be fulfilled to get the best effect is that the resistance of the secondary circuit should equal that of the telephone. This is only another way of saying that the telephone is a very badly designed motor, with such an enormous combined resistance and inductive drop that the current is quite independent of its back E.M.F. A large component of the current—namely, that required to force the vibrations—is, of course, in step with the diaphragm, and, therefore, in quadrature with the back E.M.F.; in short, an idle* current in the sense that it does no mechanical work. Suppose this particular telephone is connected to the secondary of the two circuits which are given above as an example. To get maximum current we must either wind the telephone to equal the line resistance, or divide V_s into a sufficient number of turns to bring R_s up to the resistance of the telephone. The resulting ampere-turns in the telephone coils is the same in either case, and it will be simpler to choose the latter alternative, although in practice the telephone would, of course, be wound to suit the line. Using the same notation as before, and calling x the impedance of the telephone coils at frequency F, we have first to make

$$\frac{16\rho s^2 N_s^2}{V_s} = x\ ;$$

that is, $$N_s = \frac{\sqrt{V_s x}}{4p\sqrt{\rho}}.$$

Now $$C_s = \frac{E_s}{2x} = \frac{ps^3 N_s \sqrt{W_p V_p}}{8 D^3 x \sqrt{\rho}}\ ;$$

and, substituting the value just found for N_s, we find

$$C_s = \frac{ps^2 V_t \sqrt{W_p}}{128 D^3 \rho \sqrt{x}} \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

Working out the value of C_s from the data already given, the frequency being now 400 $\sim$ per second—the rate adopted by the Post Office after many trials at different speeds—and the impedance of the telephone $x = 220$ "ohms" at 400 $\sim$, we find

$$C_s = \frac{12}{10^6} \text{ amperes;}$$

that is to say, a little more than four times (4·1) the minimum for readable signals; so that the weight of copper in the lines might be cut down to a quarter of a ton, or the distance increased by multiplying by $\sqrt[3]{4{\cdot}1}$, making the distance between the centres of primary and secondary circuits 16 kilometres (10 miles).

It is clear, therefore, that in the absence of wave-absorption an ordinary telephone without any modification will enable induction telegraphy to be carried on at considerable distances. In the absence of any measurements of the absorption of electromagnetic waves by the earth it is, of course, impossible to predict to what distance it will be possible to signal by means of a system working at 400 periods per second, but the author is inclined to think that at this speed absorption will rapidly damp out the waves as the distance increases.

* The author regrets to see that Dr. Thompson sanctions the inappropriate phrase "wattless current" for a current in quadrature with the E.M.F. Such currents are, alas! only too wattful,—they are never wattless. But they are distinctly idle, in that they never do any useful work.

Digitized by Google

The telephone may easily be improved for signalling purposes. When articulation is not required the pitch of the diaphragm may be lowered with advantage. During the working out of the apparatus for the lightship telegraph Mr. Cox devised several form of telephone sounders in which the coil was rigidly attached to the diaphragm, and adapted to move in a powerful magnetic field. One or two instruments of this type were made, and worked well. Time, however, did not allow of our bringing any of them to perfection. But in whatever way the telephone may be improved as a motor, the most serious difficulty will always remain. To get an easily audible note, it is necessary to work at a fairly high frequency. At 100 periods per second one can just hear a low hum in a telephone, but it is not until the frequency reaches 200 or 300 that dots and dashes become at all distinct. At 400 periods the note is sufficiently piercing to enable an operator to read a message without any serious strain. Whatever form the telephone as a "sounder" may ultimately take, its suitability for induction telegraphy must depend on the degree of absorption met with in practice. If absorption is serious, audible indications must be abandoned, and an indicator working at a very low frequency will become necessary. What form such an indicator should take for Morse code signalling is by no means clear, but a simple form of vibratory indicator devised by the author in 1892 for use in connection with the light-vessel experiments may be described, as it illustrates very clearly the principles involved in all vibratory indicators of minute alternate currents, and possibly contains the germ of a practicable "speaking" instrument.

The essential parts of the author's indicator are shown in Fig. 1. A rectangular loop of fine wire, a, b, c, d, is fixed in an insulating block in a position which allows its end b—c to move freely in the air-gap of a magnet, N S. When the rectangle is traversed by an alternate current it vibrates up and down about its fixed ends a—d, and if the rectangle is tuned so that its free period of vibration is equal to the periodic time of the current, it becomes an exceedingly sensitive alternate-current voltmeter, the amplitude being strictly proportional to the impressed E.M.F. on the terminals of the rectangle.

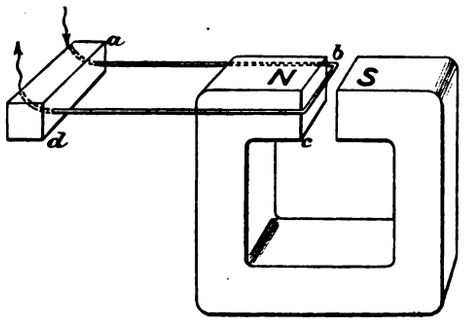

FIG. 1.—Vibrating Rectangle, with Magnet.

By combining the mechanical equation of motion with the equation of the electrical quantities concerned, the following simple equation is arrived at for the amplitude in terms of the molecular and other frictional resistances to motion, the condition of synchronism or resonance being assumed :—

Let a = amplitude at end b—c.
r = force required at end b—c to overcome frictional resistances at unit velocity.
R = electrical resistance of circuit, including rectangle.
L = self-induction of circuit, including rectangle.
E = impressed E.M.F.
$h = \mathrm{H}l$ = field in air gap × length b—c.

Then
$$a = \frac{\mathrm{E}h}{p\sqrt{(h^2+\mathrm{R}r)^2+r^2p^2\mathrm{L}^2}} \quad . \quad . \quad . \quad . \quad . \quad . \quad (6)$$

Also, if i and v are instantaneous values of the current in, and velocity at the end of rectangle,
$$hi = rv,$$
and the maximum velocity is pa; so that, if C is the maximum value of current,
$$\mathrm{C} = \frac{rpa}{h}.$$

Also the maximum back E.M.F. $-\mathrm{V} = pah$; hence maximum power is
$$\mathrm{VC} = ra^2p^2 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (7)$$

By differentiating (6) it is seen that a will have the greatest possible value when the field is adjusted until
$$h^2 = r\sqrt{\mathrm{R}^2 \times p^2\mathrm{L}^2}.$$

Writing R' for $\sqrt{\mathrm{R}^2+p^2\mathrm{L}^2}$, we have for the value of amplitude under most favourable conditions,
$$a = \frac{\mathrm{E}}{p\sqrt{2r(\mathrm{R}+\mathrm{R}')}} \quad . \quad . \quad . \quad . \quad . \quad . \quad (8)$$

The condition for maximum amplitude is clearly that for maximum activity also, and accordingly we find that when L=0 and $h^2 = \mathrm{R}r$, the back E.M.F. is equal to half the impressed E.M.F.

So much for the theory of this simple alternate-current synchronous motor. It is gratifying to add that its actual behaviour is, within the limits of observational error, strictly in accordance with theory.

By adding a fixed contact screw adjacent to the free end of the rectangle a local circuit will be closed whenever the vibrations are sufficient to make the rectangle touch the contact screw. Another and better arrangement is to have two rectangles connected to two separate secondary circuits in such a direction that they oscillate in opposite phase. The two rectangles being made, the poles of a local circuit can be made to act as a relay on coming into contact with each other. Two relays of this type were made by the author's firm in 1896 for use in the light-vessel trials, and a few months ago they were attached to the wireless telegraph erected by the Post Office for communicating between Lavernock and Flat Holm, in the Bristol Channel. They are in daily use as relays for closing a call-bell circuit. The primary current is derived from a small alternator with a very heavy fly-wheel on the armature shaft. The machine being driven by hand to a speed above the synchronising frequency, the exciting current is switched on, and the alternator allowed to come gradually to rest—passing slowly through the synchronising speed, so that the two rectangles of the distant relay have time to come to their maximum amplitude. The rectangles in these two relays are made of iridio-platinum wire 3 mils in diameter. They are each 4cm. in length, 2cm. in breadth, and their frequency is 16 periods per second. The twin-rectangle relay has one great advantage over the single pattern shown in Fig. 1. When the twin rectangles are properly tuned to unison it is almost impossible to bring them into

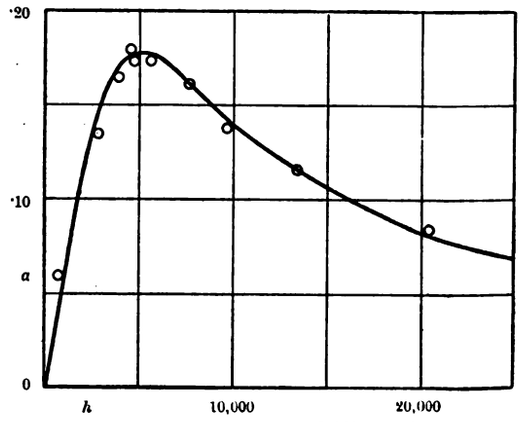

FIG. 2.—Curve connecting a and h for Iridio-Platinum Rectangle: a in centimetres, h in C.G.S. lines.

contact by shaking the instrument. Even when the contact points of the rectangles are separated by only 0·002 inch, it is difficult to make contact by shaking the relay. They may be oscillating over a large angle; appearing to overlap each other, but oscillating in unison and in the same phase, as the rectangles do when shaken, they do not come into contact. These relays were designed for use on board a light-vessel, and entire freedom from accidental contact due to shaking was, of course, essential.

Measurements of the value of the frictional resistances of rectangles made of copper, platinum, and iridio-platinum were made, and showed very little difference between them. The value of r was determined by means of a vibrator like Fig. 1, having its field produced by an electromagnet, so that h could be varied. The process consisted in observing the amplitude at synchronism for different values of h, and plotting the curve connecting them.

There being no self-induction in the circuit, the amplitude follows the law,
$$a = \frac{\mathrm{E}h}{p(h^2+\mathrm{R}r)}.$$

The impressed E.M.F. was provided by a secondary circuit of a single turn in which the total induction B could be measured. That is to say, $\mathrm{E} = p\mathrm{B}$; so that
$$a = \frac{\mathrm{B}h}{h^2+\mathrm{R}r} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (9)$$

Having plotted the observed values of a and h, a curve is determined by means of equation (9) to fit the observed points as closely as possible. One of the curves is given in Fig. 2. It shows the relation between a and h for a rectangle of iridio-platinum wire 3·3 mils diameter and 2·9cm. long, having a frequency of 25 periods per second. The curve is drawn from the equation,
$$a = \frac{1{,}770h}{h^2+25\times10^6} \text{ cm.};$$
so that
$$\mathrm{R}r = 25\times10^6 \text{ C.G.S. units.}$$

Digitized by Google

Now $R = 4{\cdot}28$ ohms $= 4{\cdot}28 \times 10^9$ C.G.S. units; hence

$$r = \frac{25}{4{\cdot}28 \times 10^3} = \frac{5{\cdot}85}{1{,}000} \text{ dynes.}$$

In the relays on the Lavernock-Flat Holm telegraphs the greater length of rectangle—4cm.—results in a lower value for r, namely,

$$r = \frac{4{\cdot}0}{1{,}000} \text{ dynes.}$$

The power required to work a 4cm. rectangle at any amplitude can now be calculated from the value for r just given, and the known frequency—16 periods per second—for, as we have already seen, the mechanical power expended is

$$M = ra^2p^3.$$

Let $r = \frac{4}{1{,}000}$, $a = \frac{1}{10}$cm., $p = 2\pi \times 16 = 100$;

then $M = 0{\cdot}4$ ergs per second ($a = 0{\cdot}1$cm.):

or, if $a = 0{\cdot}01$cm.,

$M = 0{\cdot}004$ ergs per second ($a = 0{\cdot}01$cm.);

and so on.

An amplitude of one-tenth of a millimetre is, however, far more than is necessary under favourable conditions. The author has repeatedly worked a twin-rectangle relay with less than 2 mils between the contacts, and a relay was purposely set up at Woodfield Works with the contacts 2 mils apart to ascertain how often accidental shaking made contact. The relay was tested every day by alternate current, to see that it was in working order, but in the course of a three weeks' trial no accidental contact occurred. Taking 2 mils—say, 0·005cm.—as the limiting value for the clearance between contacts, the mechanical power expended becomes

$M = 0{\cdot}001$ ergs per second ($a = 0{\cdot}005$cm.).

This must be considered as the limit of sensibility for this particular relay. When the clearance is reduced to less than 2mm. difficulties arise from the electrostatic attraction between the rectangles drawing them into contact, and when in contact the elastic force of the wires is insufficient to pull them apart again. It is clear, however, that the energy received in a secondary circuit can be detected by means of a synchronous vibrator of the kind described, in which frictional resistance has been reduced to 4×10^{-3} dynes. Returning to equation (4^a), and assuming the resistance of the rectangle is negligible compared with the least possible resistance of the secondary circuit, we can now write—

$$M = ra^2p^2 = \frac{p^3s^4 W_p V_t^2}{32^2 D^6 \rho^2}.$$

Hence,

$$a = \frac{s^2 V_t \sqrt{W_p}}{32 D^3 \rho \sqrt{r}}. \quad \ldots\ldots\ldots \quad (10)$$

When, as in the former example, $V_t = 1{\cdot}1 \times 10^5$ c.c., $s = 10^5$ cm., $W_p = 200$ watts, $D = 10$ kilometres, $\rho = 1{\cdot}7 \times 10^{-6}$ ohms, and, in addition, $r = 4 \times 10^{-3}$ dynes, the amplitude will be

$a = 0{\cdot}014$ cm. (about $5\frac{1}{2}$ mils);

so that, if the rectangle is used as a relay, and set to its maximum sensibility, it would be possible to work with a weight of copper amounting to

$$1{,}000 \text{ kilos.} \times \frac{0{\cdot}005}{0{\cdot}014} = 350 \text{ kilos.},$$

or about one-third of a ton.

Or, still using 1,000 kilos., the distance may be increased by multiplying by $\sqrt[3]{\frac{0{\cdot}014}{0{\cdot}005}} = 1{\cdot}42$, bringing up the distance to 14·2 kilometres—a value only a little less than the limiting distance found for readable signals with a telephone as receiver. A very small rate of absorption of waves would, however, tell enormously against the telephone, while the vibrating rectangle, working at so low a frequency as 16 periods per second, would not be appreciably affected.

It is interesting to note that when the telephone and the rectangle are worked under exactly the same conditions as regards primary power and distance and size of circuits, but at frequencies of 400 and 16 periods respectively, the total power available for the telephone is more than six hundred times as great as that available for the rectangle. Yet the rectangle gives a *visible* indication—for by means of a magnifying glass the vibrations are easily visible down to about half a mil. It has already been remarked that this synchronous vibrator may contain the germ of a "speaking" instrument. It has ample sensibility for practical purposes, and is not likely to be affected by a moderate rate of absorption. It is to be hoped that some means will be discovered for enabling it to be used for indicating Morse code signals, either directly or by employing it as a relay.

Absorption.

So far as the author is aware, the absorption of electromagnetic waves by the earth—considered as a solid conductor—has never been calculated or measured under the conditions assumed in this Paper. What is wanted is a complete series of observations of the absorption at different frequencies and over different distances, and it would be desirable that observations should be made in several different localities of widely differing geological character. The author hopes to be able to carry out at least a part of this investigation in the course of the next few years. Apart from absorption, it is clear that communication by magnetic induction can easily be established in those cases where the ordinary telegraph line or cable is impracticable. The author has endeavoured to illustrate the fundamental principles involved in the working of induction telegraphs, and if he has in any way cleared the ground for future investigators, and thrown a little light on matters relating to the design of appropriate receiving apparatus, the object of this Paper will have been fulfilled. In conclusion, the author desires to express his sense of the great obligation he is under to Mr. Preece and Mr. Gavey for their kindness in giving facilities for his investigations, and placing at his disposal the results of the many experiments carried out by them in connection with wireless telegraphy.

TRAMWAY CONSTRUCTION OVER CHILKOOT PASS.*

BY W. A. BURKHOLDER.

Building an aerial tramway over Chilkoot Pass, or rather, to speak more accurately, the building of an aerial tramway *up* the Chilkoot Pass from the foot of the canyon to Scales, at the summit of the mountain, is an engineering problem of expedients and frontier experiences, rather than of technical detail. To begin with, the work was of the variety best known as a "rush job," but to make matters more interesting, the contract was executed in the depth of an Alaskan winter, with labour mildly characterised as "unskilled," and in a country where the monotony of having different parts, if not the entirety, of one's anatomy frozen, was varied only by the excitement of death-dealing avalanches. Labour—spare the mark!—cost $3·50 to $5 a day and board. At times it was necessary to dig through 20ft. of snow before reaching the ground, and then, particularly during the last two miles of the line, the ground proved so hard that it was almost impossible to break it with dynamite, to say nothing of the difficulty, if not the impossibility, of thawing the explosive. It was at all times necessary to put the poles into the holes as soon as the latter were dug, or otherwise the holes would quickly fill with drifting snow. As to the weather, that at the foot of the summit is of a severity I cannot describe. It is with the greatest difficulty, at times, that one can stand up against the hurricane that blows there, and this, with a temperature perhaps far below zero, makes it almost impossible at times for human beings to exist there for any length of time. Both my cheeks were frozen one morning while making an inspection of the line, and a few days before the hard frozen bodies of two Indians were taken from the trail. It was below this point that occurred the great avalanche of February last, where nearly 60 adventurous gold-seekers were buried alive, and which was so fully reported in the daily Press at the time. Although the great avalanche crossed the pole line of the Dyea-Klondyke Transportation Co.'s tramway, it did not injure it beyond tearing down a few stretches of wire. Nevertheless, the work on the tramway, which was begun on June 15th last, was completed on March 20th, when it commenced operations. The original plans for the building of the tramway of the Dyea-Klondyke Transportation Company contemplated the erection of a power house, to be driven by steam, at Dyea, and an 18-mile transmission thence to Scales, at the foot of the pass. This transmission was to be at 5,000 volts, three-phase, with step-up and step-down transformers, and the equipment for it reached Dyea in January. On arriving on the ground, however, I advised against the transmission as proposed from Dyea, when the power house could be both installed and operated as cheaply and as satisfactorily at the mouth of the canyon as at Dyea. Some 11 miles of transmission line, as well as the raising and lowering transformers, and all attendant losses would be obviated should the change be effected, and, accordingly, the power house was located at the mouth of the canyon.

The generating station is a plain log building measuring 20ft. by 60ft., and the steam equipment place therein consists of a 16ft. by 64in. marine type boiler, and an 11in. by 12in. automatic engine, from which is belt-driven a Westinghouse 45 kilowatt two-phase generator, delivering 2,000 volts. The station contained no "frills," but the behaviour of the boiler is worthy of special mention. It was of the marine type, designed for burning coal under forced draught, but no coal was to be had. The only wood available was green hemlock, at $5·50 per cord, and while we did succeed in getting up steam, I have often thought that it was due to the sulphurous heat of the fireman's outbursts of wrath more than to any calorific virtue of the wood itself.

Canyon City is nine miles above Dyea, which is the seaport for those who go to Dawson and the Klondyke by the most direct route.

* From the *Journal of Electricity*, of San Francisco.

Digitized by Google

The distance from Canyon City to the foot of the pass is a little over seven miles, and along this distance the pole line passes, thence up the canyon to Scales. The poles are of 30ft. spruce, cut from the mountain side, and measure from 6in. to 8in. in diameter at the top, to from 10in. to 12in. at the butt. In the canyon the line is run in the most direct route possible, the poles being set in holes blasted out of the solid rock, and so that the line runs from point to point along the side of the canyon. This pole line carries only the two-phase transmission circuit, consisting of four No. 6 B. and S. gauge hard drawn copper wires, supported on Locke triple petticoat glass insulators, on wood topped steel pins. The transmission line is barrelled twice in its length, and the poles also carry a telephone circuit.

The motor house at Scales contains a step-down transformer which reduces the line potential to 200 volts for driving a Westinghouse 15 H.P. induction motor (type "C"). The motor is belted to a shaft operating winding drums through clutches, so that one of the drums takes up the cable while the other pays it out at the same speed. The outfit is a regular mine hoist, and was, in fact, taken from the Sheep Creek Mine, near Juneau. The length of the cable, which is, of course, double, is about 4,000ft., and the greatest single span is approximately 3,000ft. in length. Loads varying from 1,200lb. to 1,500lb. are carried with ease up grades running as high as 30 per cent., and some parts of the tramway run along the side of the canyon from 500ft. to 600ft. almost vertically above the trail. It should be explained that the Dyea-Klondike Transportation Co. tramway, which is now being described, consists of a traction cable of $\frac{5}{8}$in. plow steel, supported at intervals as close as possible, on staunch overhanging pole structures. On these traction cables run, or rather underrun, two buckets, not unlike two coal conveyors joined together, and these buckets are hauled along the traction cable by means of a pulling cable, also of plow steel, but having a diameter of $\frac{1}{2}$in. It is this latter cable that is wound on one or the other of the two drums referred to, according to whether the buckets are being raised or lowered. The tramway, which is 4,000ft. in length, is used only for freight. Although employés have been over it often, and one young lady a Miss Edgerton, who is a Red Cross nurse, made the perilous trip in safety shortly after the completion of the tramway. She was the first and only woman who ever went over the trip, despite the full-page story in a New York Sunday paper describing, with thrilling attributes, the journey as made by one of its women reporters. The tramway is capable of handling 50 tons of merchandise daily, and the cost for the service is 10 cents per pound from Dyea to Lake Linderman, which is a cut from the rate of 40 cents which existed for the same service last fall. The rate for the 4,000ft. of the Pass alone is 1 cent per pound.

So great was the activity of the transportation companies during last winter, that by the commencement of the season this summer, three different tramways were in operation over the Chilkoot. In addition to the one described, the Alaska Railway and Transportation Company were operating a single 1in. cable between the top of the hill above Stone House to the top of the mountain overlooking Crater Lake. This cable has a length of about 7,000ft., and is run by a 40 H.P. gasoline engine. The third system is known as the "Bleichert system," and uses a steam plant for operating its tramway from Canyon City to Sheep Camp, and another for that section from Sheep Camp to the summit. These three systems were consolidated early last summer, and now only the Bleichert system is in active operation.

ELECTRICITY WORKS ACCOUNTS.

Harrogate Municipal Electric Supply Works.

The municipal electricity supply undertaking at Harrogate commenced business on April 15, 1897, with about 90 consumers and an equivalent of 8,000 8 c.p. lamps connected to the mains. Our table therefore embodies the accounts of working for the period from the above date to December 31, 1897.

Of the authorised capital of £40,996 £25,235 had been borrowed temporarily at one-half per cent. above the bank rate of interest, but the Corporation were about to take the loan up at 3½ per cent.

At December last the total capital expenditure had amounted to £27,298, representing £99 4s. per kilowatt of generating capacity of plant. With 110 consumers and an equivalent lamp connection of 8,700 the output for the year was 62,886 units sold, for which an average revenue per unit of 5·976d. was obtained. The total costs at 4·17d. per unit represented about 70 per cent. of the revenue.

No reserve fund has yet been started, so that with the working profit of £468, and after paying £565 as interest on loans the deficit is £97. To this a sum of £254, representing the expenses of executing the provisional order, has been added as this expenditure is not chargeable to capital account.

Windsor Electrical Installation Co. (Limited).

Electricity supply at Windsor started near the end of 1896, the equivalent lamp connection being then about 2,700, with 60 consumers, and the plant capacity about 100 kilowatts.

The authorised capital of the Company amounts to £25,000. At December 31st last the total capital paid up (raised by the issue of £1 shares) was £19,970, while the total expended capital amounted to £20,469, representing some £73 per kilowatt of generating capacity of plant in the station. It was proposed to issue the remaining capital of £5,000 during the current year.

The equivalent 8 c.p. lamp connection to the mains at December 31, 1897, was 4,985, and the output for the year—52,095 units sold—realised a revenue of £1,558, representing 7·16d. per unit. In addition to this and such other items as meter rents £84, pupil's premium £33, and rents £52, the total revenue received has been augmented by what appears to be a by no means unremunerative department of the business—the installation work—this having realised a profit of £621, thus raising the total revenue to 10·6d. per unit sold.

The costs come out high, at 5·22d. per unit, generating costs at 8·56d. being somewhat abnormal, even for the moderate output of 52,000 units.

A working profit of £1,163 has been made, representing 7·09 per cent. of the mean capital. No payment to any reserve fund has been made, thus enabling an ordinary dividend of 4 per cent. to be declared, leaving a balance to carry forward of £604.

Neglecting the profit of £621 made by installation work, the working profit would stand at £542, and the ratio of the total costs to the revenue at 67·7 per cent.

The following is a list of electric supply works the accounts of which have been analysed, together with the dates on which statements and analyses of accounts have appeared:—

Ayr (Municipal)	Nov. 11	Kens'gton & Knightsbr'ge (Co.)	Sept. 30

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal 1861—1879).

Published every Friday, Price Sixpence; Post Free, Sixpence Halfpenny

Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone: 949 Holborn. *Telegrams:* "Electrician Newspaper London."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "The Electrician," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "The Electrician" *Printing and Publishing Company, Limited, and be crossed "Coutts and Co."*

All Editorial letters to be addressed to The Editor.

All letters for insertion in "The Electrician," *or containing questions, must be accompanied by the name and address of the writer as evidence of good faith. No notice whatever is taken of anonymous communications.*

'The Electrician" is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices, as above.

New Volumes of "The Electrician" *commence in April and October.*

Subscription Rates.—The Rates for Subscriptions to "The Electrician" are as under:—

	Year	Half-Year	Quarter	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Postal Union	30s. 0d.	16s. 0d.	8s. 6d.	

"The Electrician" *offers exceptional advantages to Advertisers.* It has by far the largest circulation of any English Electrical paper, and circulates all over the World. *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

Trade Advertisements *intended for the current issue must reach the Office not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday. Wrapper Advertisements by Wednesday morning.*

Official Announcements, Auctions, *and* Small Advertisements *accepted up to 6 p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct o "The Electrician" *Printing and Publishing Company, Limited. The well-known* "Electrician" Series *of Standard Electrical Works at present consists of—*

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young, M.I.E.E. Price 10s. 6d., post free; abroad 11s.

THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By Messrs. H. K. C. Fisher and J. C. H. Darby. Price 6s. net; abroad, 6s. 3d.

BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH. Edited by C. E. S. Phillips. With an introduction on the history of Crookes Tube and Röntgen Ray work, and a chapter giving "Practical Hints," on the subject.

THE POTENTIOMETER AND ITS ADJUNCTS. By W. C. Fisher. Price 6s., post free.

LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS. By F. C. Raphael. Price 5s., post free.

MOTIVE POWER AND GEARING. By R. Tremlett Carter. Price 12s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson. Price 12s. 6d., post free.

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. Fleming, M.A. F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d., post free 13s. *Vol. II. is nearly ready.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. Fleming. VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. NEW EDITION. Price 12s. 6d., post free. VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. 93 original Illustrations, price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. Snell. 10s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. George Gore. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. Weymouth. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By Gilbert S. Ram. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Gruphl and H. M. Kilgour. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d., post free. New edition in the press.

"THE ELECTRICIAN" PRIMERS. In Two Vols. Paper covers, 2s., post free, 2s. 3d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d.

WIRELESS TELEGRAPHY: Signalling across Space without Wires by Electric Waves. By Dr. O J. Lodge. Enlarged Edition. Price 2s. 6d. net.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c. By A. C. Curtis-Hayward, B.A. Price 3s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont. Price 3s. 6d., post free.

FULL CATALOGUE POST FREE ON APPLICATION.

"ELECTRICIAN" SERIES FORTHCOMING BOOKS.

ELECTROMAGNETIC THEORY, VOL. II.—By Oliver Heaviside. The second volume of this important work is in an advanced stage, and will be ready shortly.

PRACTICAL TELEPHONY.—By Dane Sinclair and F. C. Raphael.

PRIMARY BATTERIES.—A work on this subject will shortly be published, bringing the theory and practice of the Primary Battery up to date. The book will be fully illustrated.

SECONDARY BATTERIES.—By E. J. Wade. Fully illustrated. The Author in this work will deal briefly with the theory and fully with the chemistry, design, construction and manufacture of secondary batteries or accumulators.

"THE ELECTRICIAN" WIREMAN'S POCKET-BOOK.—"The Electrician' Company will shortly publish a valuable pocket-book for the use of those engaged in wiring work, both external and internal.

CARBONS FOR ALL ELECTRICAL PURPOSES.—By Francis Jehl. A work will shortly be published dealing fully with the manufacture of carbons for all electrical purposes. The book will illustrate the machinery and apparatus used in carbon manufacture on the Continent and in America, and will give the latest practice in this important subject.

THE ELECTRIC ARC.—By Mrs. Ayrton. This work will shortly be published, and will contain an historical sketch of the early experiments on the electric arc, as well as the important results of recent research.

SPECIAL NOTICE.

NOW READY.—Vol. XLI. of "The Electrician," bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

A complete set of the Second Series of "The Electrician" can now be supplied. These sets are very scarce, and early application should be made.

ELECTRICITY IN STAGE-LAND.

The history of electricity in the theatre is both instructive and interesting, revealing as it does remarkably rapid progress from small beginnings to its present important position among affairs theatrical. Before and behind the footlights, though more especially in the second-named domain, the ornamental and useful possibilities of the electric current have gradually been appreciated and utilised to an increasing extent. In the apprentice days—or nights, should we say—of electricity in stage-land, its duties were more ornamental or fantastic than severely utilitarian. Corps de ballet were equipped with belts of now obsolete primary or secondary cells, lighting lamp-tipped magic wands; "chipped lightning," as we believe it was called, was a popular stage effect, produced by the sparks from a large Wimshurst machine; and the demoniacal flash that leaped from the sword of Mephistopheles when he slew Valentine was produced by an artfully-contrived induction coil, which, on one occasion at any rate, gave the unhappy man a shock that "greatly tickled the devil" and much amused the audience. These were amongst the many quaint uses to which electricity was first applied, at a time when the electric light as a main illuminant in the theatre was but little known and was at best a somewhat heroic experiment. But this was also a time when electricity was rapidly revealing its potential superiority as an illuminant, and when the shadow even of its advent as a motive power was dimly forecast. And despite the many seemingly insurmountable difficulties, and the lamentable failures which met the efforts of those who endeavoured to supersede with electricity older methods of lighting theatres, this form of illuminant has gradually come to be recognised by theatrical managers as the only safe and satisfactory one both for general lighting and for artistic stage effects. Stage scenery and properties are, as a rule, so highly inflammable that it is not surprising that the glow lamp bulb should be preferred to the wire-encased or naked gas flame, or the electric arc to

Digitized by Google

the dangerous oxy-hydrogen "lime." An example of the completeness and even elaboration with which the electric light equipment of a theatre is now invested is to be found at the recently-opened Kennington theatre. At that house Messrs. Owen Lucas and Pyke have erected a self-contained steam-driven electrical plant of some 2,000 lamps capacity. An account of this installation will be found in an article we publish this week.

As with the outside prosaic world, the people of stage-land were more ready to realise the advantages of electricity for lighting than for mechanical power purposes. Indeed, the theatrical profession was and still is far behind the general public in this respect; for it appears to possess no engineering tradition whatever. Not merely electrical power, but every form of mechanical power is practically unknown in stage-land, where, with but few exceptions, all scenic constructional work is done by carpenters, and all operations are effected by hand. The stage has never been thoroughly engineered. In the larger cities of Europe, at some few of the principal houses, hydraulic power has been introduced for operating the stage floor and turn-tables; and this source of power has also been used to a limited extent at Drury Lane Theatre and in one or two other houses in the United Kingdom. But the vast majority of even large modern stages are quite unengineered, and the traditional methods to be found on them compare with modern engineering practice much as a rope-hauling crowd of ancient Assyrians would compare with an electric motor. The reason for this is probably to be found in the predominance of traditionary modes of constructing a stage, and the difficulty, to say nothing of the cost, of adapting stages built on older lines to the more modern ideal. Yet in sanitary, acoustic and other respects the theatre has been advanced to meet the latest requirements, so that it is not impracticable that its stage should be properly engineered and equipped with all the convenient appliances which the introduction of cheap electric power renders available. We publish in an article this week some account of the work that has just been accomplished by Mr. E. O. Sachs in the electrical operation of part of the stage at Drury Lane Theatre. Looking not merely at the electrical plant, but having regard to the solid construction of the stage, it will be seen how great and radical a change in stage structure the adoption of mechanical motive power, such as electricity, involves. Instead of a clumsy contrivance of timber beams we have a series of light steel girder-built arches, a form of structure that is well adapted to rapid yet silent motion and adjustment. Apart altogether from the use of electricity, this transition is in itself a decided advance, and it is surprising to learn that so late as the present year of grace its superiority has first been recognised. Turning to consider the advantages directly resulting from the use of electric motors, we may observe that (1) cheapness, (2) rapidity, silence and certainty in action, and (3) the enhanced safety secured, are among the most important features. The compactness of electrical plant is also often one of its advantages. As regards most of these points little need be said by way of defence; those who are in a position to compare electrically driven machinery with similar machinery worked by a group of men or by hydraulic power, will readily bear out our assertion that the first is the most convenient of manipulation and the readiest in regard to rapid adjustment. In the matter of cost, we understand that one of the principal inducements which led Mr. Arthur Collins to adopt electricity for the Drury Lane stage was the low cost of power as compared with hand or hydraulic working. When it is remembered that the actual time during which the motors consume power is very small, it will easily be seen what great economy must be effected by their introduction. The success which thus far has attended the electrical equipment at Drury Lane Theatre will go far to encourage the adoption of electric motive power in other houses. Indeed, we hear that several theatrical managers are already considering the matter with a view to extending its use to their own stages.

REVIEWS.

Jahrbuch der Elektrochemie. By Dr. W. Nernst and Dr. W. Borchers (Halle-an-S: W. Knapp. 1898.)

This is the fourth time that the Jahrbuch has appeared. The work has already established its position as a useful repertory of all that concerns the electro-chemist, and the present issue does not fall behind its predecessors. The editors have obtained the aid of three collaborators (Dr. H. Danneel, Dr. F. W. Küster and Dr. K. Elbs) in certain sections of the work, but the greater part of it remains as a monument to their own industry.

The book is composed of two main divisions. The first deals with the results of researches in electro-chemistry which may be regarded as purely scientific; the second describes such technical advances as have been achieved during the current year. In the former we notice a summary of the conclusions of Förster and Seidel concerning the conditions necessary to be observed to ensure the accuracy of the indications of the copper voltameter. Recognition of the possibility of the existence of cuprous copper in the ordinary cupric sulphate solution, is needful if irregular deposits are to be avoided. The precautions laid down agree generally with those which have been already arrived at in a purely empirical manner—a result not uncommon in research, but not cause for invidious comment on that account. The usual batch of determinations of conductivity in electrolytes agreeing nicely with predicted figures is not lacking. The quantity of work recorded is large; its quality not so easily to be appraised. Without carping, one may fear that true knowledge of the nature and principles of electrolysis may run some danger of being smothered beneath a mass of facts and pseudo-facts. It is necessary to be discriminating, "distinguishing fyttes which appal and disgust from fyttes which are simply inane," if we may risk a rough quotation. A short section on electrolytic analysis, sandwiched between the scientific and technical parts of the book, contains little of note save a description of Hollard's method of copper analysis which is an attempt to extend his useful process for the determination of copper to those impurities commonly found in the commercial metal.

In the technical part of the book there is much of highly practical interest. Many of the more notable articles and Papers which are abstracted have appeared as original matter or translations in *The Electrician* during the past year. A most elaborate *précis* is given of the experiments of Liebenow and Strasser on the Jacques carbon cell, from which the authors have drawn more favourable conclusions concerning that device than have most other investigators. There is a similarly prodigal devotion of space to the Borcher's gas cell. Dr. Elbs, who is responsible for this part of the book, displays some needless irritation at our *exposé* of that *chimæra bombinans* in CO. Such chastening as we administered was necessary, and we trust not unwholesome, and should be received in a gracious and docile spirit, not with partisan cries.

The chapter on accumulators is concerned chiefly with the description of mechanical improvements in plates and cells. There is no news yet of a workable secondary cell independent of lead for its action. Considering the flood of devices which have been invented for electric furnace work, the chapter on this subject is commendably short. That it might have been much longer is shown by the string of patents at the end. We have in previous years referred with approval to this useful list of patents. It is good as it stands, and in our judgment might have its range extended to include some

Digitized by Google

of the barren and tedious contrivances which are allowed the privilege of description in the text. We admit freely that the task of discrimination is no light one, but we would suggest to the authors that they might next year be less lenient in their admission of the irrelevant and absurd. On p. 266 is a description of an ingenious attempt to induce the crystallisation of carbon in the diamond form, by the simultaneous application of heat and pressure, using means which are certainly novel and striking. Briefly, it consists in heating by means of the arc, a piece of carbon attached to a piston rod carried by a piston working in a vertical cylinder. When the carbon is at the highest temperature of the arc a charge of gunpowder is exploded in the cylinder, and propels the piston, so that the piston-rod carrying the carbon is driven with great violence into a small cavity in a steel block. The carbon is thus strongly compressed while at its boiling point, and is, in consequence, partly converted into microscopic diamonds. The chapter on the manufacture of aluminium does not contain mention of any great novelty, but gives an interesting estimate of the world's production for 1898, which is set down as 6,000 tons. A good deal of information is given regarding the working up of anode sludge and purifying the electrolyte in the copper refining industry. Incidentally occurs a significant comment which may be taken to heart by those who believe that the possession of a German patent implies any particular novelty in the invention. "Je bekanuter die Reaktion, desto leichter augenscheinlich die Erlangung eines deutschen Patentes in Klasse 40." Under the head of nickel is set down a most elaborate process of nickel smelting which should act like a charm, and indeed reads like a bad dream. The appended diagram is a work of much art.

The excellent work of Förster on the conditions necessary for the electro-deposition of nickel in plates of reasonable thickness, so that its refining becomes a practicable proceeding, is noticed. It was duly described in *The Electrician* shortly after its appearance. Naturally there is a good deal about calcium carbide and its manufacture. Useful information is given concerning the various industrial ventures which have entered this trade, but there seems little substantial improvement in furnaces or methods. One thing is clear—viz., that there is a very considerable market for carbide at a reasonable price, whence one deduces that there must be a greater amount of acetylene lighting that seems probable to a dweller in civilised regions; doubtless it serves for remote and desolate places—*e.g.*, country houses.

The section on the alkali and chlorine industry is comparatively meagre, not, as we think, from any oversight or neglect on the part of the authors, but because of the accomplished or impending collapse of the various impracticable schemes which have troubled this manufacture, and the steady, silent growth of the few good processes which have been devised in the years of struggle now almost past. The book closes with a short chapter on electrodes, diaphragms and such necessary instruments of electrolysis.

We have indicated our opinion of this work sufficiently clearly in running comment. We reiterate that it is a book of merit and usefulness; when it errs, the error is on the side of commission rather than of omission—an excellent fault in a work of reference.

Alternating Currents of Electricity and the Theory of Transformers. By ALFRED STILL, A.M.I.C.E. (London: Whittaker and Co. 1898.)

Notwithstanding the fact that the literature dealing with the theory of alternating currents and the alternating-current transformer has received many and important additions of late, a perusal of this little book by no means gives us the impression that it is redundant. As the author remarks in the preface, there was room for a small work "in which the principles determining the behaviour of single-phase alternating currents under various conditions are considered less from the scientist's point of view and more from an engineering standpoint than is usually the case," and we must admit that the author's treatment of the subject shows that throughout he has kept his objective, as thus defined, well in mind.

Analytical treatment is abjured—graphical methods being almost exclusively used from beginning to end. The first 19 pages are devoted to a consideration of magnetic principles, and very satisfactorily leads up to what follows on alternating currents. The effect of magnetic saturation on leakage is more clearly dealt with than is usual. A commendable feature of the book is the care that has been taken—in a work such as this, written for purely practical men—to show the effect of wave form, and when and where come in the limitations and errors due to assuming the electrical quantities varying as a sine function. Most of the cases likely to arise in practice, involving self-induction and capacity, singly and in combination, are dealt with by the aid of the never-failing clock-face diagram.

A problem instructive to students is that dealing with the result, under certain conditions, of shunting with an inductionless resistance a choking coil, which is connected in series with a non-inductive resistance. In consequence of the closing of the shunt to the coil the total impedance of the circuit is increased and the total current drops in consequence of a shifting in the phase relations. An analogous case in connection with a transformer is given further on in the book. *Apropos* of these effects we might mention another experiment based on the phase-shifting principle. If a choking coil provided with a few auxiliary turns of wire—distinct from the usual coil and normally kept open-circuited but capable of being short-circuited be included in a circuit having certain proportions of resistance and self-induction, the current flowing through the circuit is increased, though the pressure across the choking coil falls when the auxiliary winding on the coil is short-circuited.

In referring to Dr. Fleming's method of plotting the curve of magnetisation from the E.M.F. curve, we notice that the author criticises Dr. Fleming's diagram in this connection given in his 1896 Cantor lectures before the Society of Arts, but surely it is but a matter of convention whether a wave diagrammatically shown as displaced in phase to the left of another wave is to be taken as preceding or as following the latter in the absence of a definite origin being indicated on the abscissæ. In fact, in some of the diagrams representing phase relations in "The Alternate Current Transformer" Dr. Fleming diagrammatically denotes a lagging wave by a displacement to the left.

The author gives a very clear exposition of the experimental determination of leakage drop in transformers; on the other hand, more attention might usefully have been given to the treatment of the subject of transformers with large leakage for supplying arc lamps from constant pressure circuits. In discussing this case the assumption is made that an arc lamp is a non-inductive device. Not till a later section is any mention made of the large influence exercised by self-induction in the secondary circuit on the leakage drop in secondary pressure between various loads. The section on transformer core losses is well up to date, and includes a brief and useful summary of the result of recent investigations on the influence of wave form on these losses.

An index is provided in addition to the table of contents at the beginning of the book, which forms one of "The Specialists' Series."

Practical Telegraphy. By H. W. JENVEY, Electrician and Electrical Inspector, Victorian Post and Telegraph Department. Two vols. (Melbourne: Robt. S. Brain, Government Printer. 1898.)

Although not in all respects suited for the telegraph operator of this country, these two handy volumes may be cited as excellent samples of what such handbooks ought to be; and we are desirous of bringing them under public notice, if only to emphasise the fact that there is no such work provided for their staff by the British postal telegraph authorities. Mr. Jenvey has taken upon himself to educate his subordinates, a task which he has performed with infinite pains, and a great deal of skill; what is more, his efforts are so much appreciated that these volumes bear the imprimatur of the Postmaster-General of Victoria, and are published by the Colonial Government as "A Guide for the use of Officers" of the Department. They are essentially of the Blue Book order of publication, and appear to be distributed among the employés gratuitously. Vol. II., which is devoted to the description and explanation of Duplex and Quadruplex signal-

Digitized by Google

ling, and to the higher branches of testing and measurements, would be a welcome addition to the technical handbooks of the mother country, the text being full, clear, and concise; the illustrations profuse and well drawn. Submarine telegraphy is, of course, left out of account; but when this is said, the book remains one of the best that could be put into the hands of an intelligent operator, or indeed of any student of the practical and technical aspects of overland telegraphy. Of the first volume, although it has gone through three editions, and has well deserved its popularity, we cannot speak in such unqualified terms. This, however, is chiefly due to the prevalence of working with "closed circuits," a practice which has long been out of favour in this country, and which consequently destroys the utility, for English readers, of a great deal that is described and illustrated in Mr. Jenvey's book. Making due allowance for this, the descriptive matter is always simple and to the point, leading the student gradually on from a working theory of the elementary stage to the more obscure problems that confront the expert electrician. The illustrations in this volume, however, suffer as they usually do at the hands of the draughtsman or the engraver. Where the author himself has made the drawing matters are generally pretty plain; but when a draughtsman has been left to draw the apparatus he has followed the common practice of sketching a pictorial front view and leaving out all the, electrically speaking, essential details. This is the case with Fig. 22, where not only the connections, but the lettering referred to in the text, are omitted. As a rule the tongues of relays are balanced midway between the stops, and, what is far worse, the Morse keys are in touch with neither the anvil nor the back stop. Fig. 32, for example, would be unintelligible to a novice, the current not being traceable in any direction. Even the diagram relating to Wheatstone bridge testing is by no means clear; but this is remedied in the second volume. On page 11 either Fig. 10 is wrong or the text is so, the circuit requiring both keys to be depressed. This is so stated at the beginning of the paragraph; but, later on, "key" is used in the singular, whilst the diagram flatly contradicts it. There is a strange slip at the top of page 40, where the letter F is probably meant for a D. We notice, too, that no mention is made of the use of a permanent magnet for restoring demagnetised needles. The process described in the text is effectual, certainly, but far more troublesome, we should say, than handling a horse-shoe magnet. We have only one other fault to find with these two useful volumes—and this by way of compliment—the index to each of them falls far short of what their contents entitle them to.

The Archives of the Rontgen Ray. August, 1898. (London: Rebman Publishing Company.)

The current number of the "Archives of the Röntgen Ray" reports, as usual, the doings of the Röntgen Society of London, and contains, as well, an interesting collection of data bearing especially upon the medical applicability of the rays. That energetic body, the Röntgen Society, has had read before it Papers by Mr. Apps, Dr. Macintyre, Mr. Swinton and some other enthusiasts, a distinct feature of the meetings apparently being the often excellent discussions which followed. Mr. Apps discourses upon a new induction coil—what could be more appropriate?—and criticises severely some statements recently put forward by M. Rochfort in connection with an apparatus introduced by him. As there are no illustrations to Dr. Macintyre's article upon "contact breakers," his contribution is not of that real practical use which it otherwise might have been; it may serve, however, to emphasise the existing want of more perfect means for interrupting the primary current in induction coils. What can have induced Drs. Wolfenden and Forbes-Ross to publish a "preliminary note" as to the "Action of Röntgen Rays upon the growth and activity of Bacteria and micro-organisms" is difficult to understand. At the present state of that question, with so much uncertainty rife, when, in fact, there is held in many minds the belief that X rays exert no action whatever upon micro-organisms, the results set forth in this addition to the literature of the subject can scarcely be considered helpful. We were unable to perceive that the authors had taken any special precautions in regard to the "earthing" of the cultures. What is really wanted at this time is a thorough and systematic examination of the whole question, and it is to be hoped that Drs. Wolfenden and Forbes-Ross will, in the near future, supply that want. The pin-hole camera has been turned to good account by Mr. Swinton, and on page 15 of the "Archives" there is a description of its useful application to X-ray problems.

Everyone who has treated Röntgen ray matters at all seriously knows of the early work done at Oxford by Mr. Porter, and will be glad to see here collected the curious results of his observations. This complete account of his work, got together, as he explains, at the request of the Röntgen Society, occupies some eighteen columns of exceedingly interesting reading. The "Archives" this time contains a description of "Some X-ray appliances," besides a few scraps of miscellaneous information and the usual "Notes and Abstracts"; there are also comprehensive articles upon "The Röntgen Rays in the Diagnosis of Pulmonary Tuberculosis," "Experiments on the Application of the Röntgen Rays to the Study of Anatomy," and so forth. Then come the "Plates," which are always good—seven beautifully executed photographic reproductions.

The "Archives of the Röntgen Ray" is keeping up its reputation for thoroughness in this respect, and the journal fills a very definite place amidst the scientific literature of the day.

Chemistry in Daily Life. Popular lectures by Dr. Lassar-Cohn. Translated by M. M. Pattison Muir, M.A. Second edition, revised and augmented. (London: H. Grevel and Co. 1899.)

The fact that this book has run to a second edition is proof sufficient that there is a demand among the general public in this country for information respecting those technical processes which conduce so much to the comfort of our everyday life, and this is a very satisfactory state of things. But why should Mr. Pattison Muir have thought it necessary in order to meet this demand to translate a series of lectures delivered by Dr. Lassar-Cohn at Königsberg? Surely the information might have been supplied from home sources. The lectures themselves are lucid, and the explanations given of the various processes, and the underlying scientific principiples on which they are based are all that could be desired. Starting with the air we breathe, Dr. Lassar-Cohn leads us on to the consideration of how the carbon consumed in the process of respiration is to be renewed, and so on to the question of food, and the properties of its various constituents, and he notes the beneficial effects of good cookery. The properties and chemical constitution of our food and drink being explained, the question of our raiment necessarily comes under consideration, and then we pass on to the explosives used in sport and war. Toilet articles are also dealt with, and the manufacture of glass, which introduces us to mirrors, photographic lenses and the Röntgen rays, and the work concludes with a chapter on metallic alloys and the alkaloids. The author has treated his subject in a manner eminently human and suggestive, and one rises from a perusal of the work with the feeling that chemical phenomena are intimately connected with our daily life, and that, whether consciously or not, we are always carrying on chemical operations.

Kalender fur Elektrotechniker. (1899). By F. Uppenborn. (Munich and Leipsic: R. Oldenburg. 1899.)

Some of the matter contained in the fifteenth edition of this well-known pocket-book has been omitted in the sixteenth, and its place has been filled by material of greater importance. Among the additions we notice a method of estimating the return-circuits of electric tramways from an article written by Herr F. Natalis in the *Elektrotechnische Zeitschrift* this year, and a reference to the system of measuring leakage-currents, described by Dr. Kallmann at the last meeting of the Verband Deutscher Elektriker. Some alterations in the conductor tables are also apparent. The list of historical dates concludes with 1891, the date of the Frankfort Exhibition. Surely some electrical events have happened since then of equal importance to that of the first publication of the *Kalender für Elektrotechniker* in 1884.

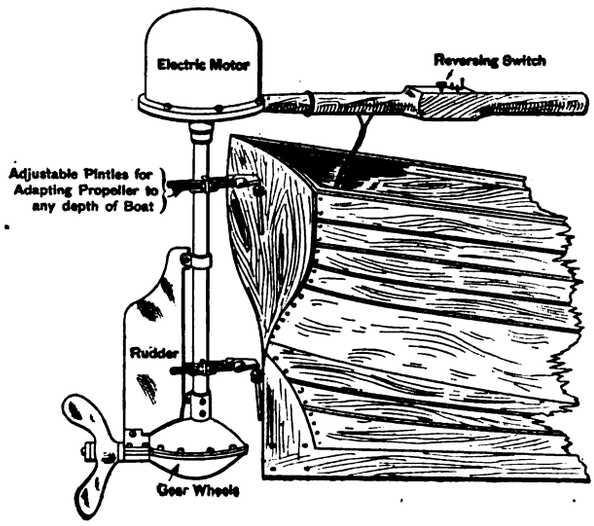
PORTABLE ELECTRIC PROPELLER FOR BOATS.

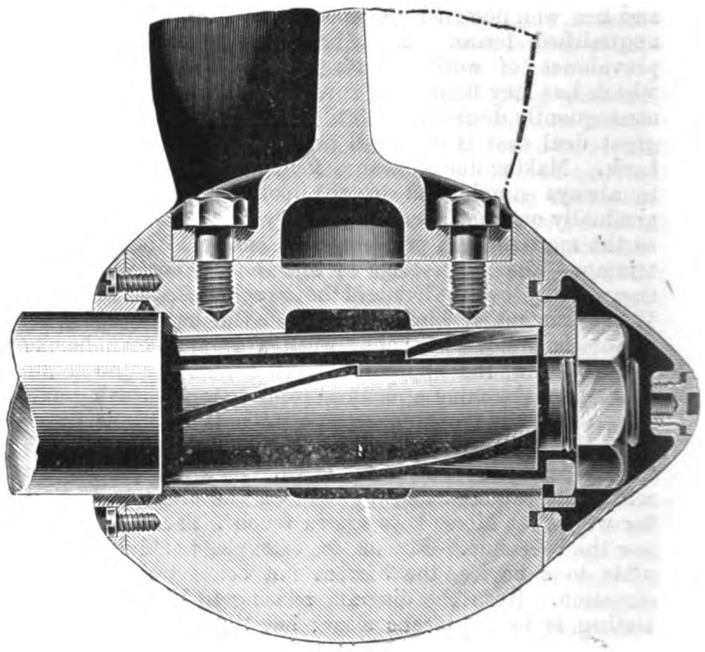
In connection with the correspondence recently published in our columns on the subject of electric canal haulage, Mr. E. A. McLachlan has sent us particulars of a portable electric propeller, which he can fit to any boats, although they may not have been originally designed for electrical propulsion. The apparatus, which is illustrated in the accompanying figure, was originally intended for river boats, but it is equally applicable to canal barges. To apply it, it is only necessary to unship the ordinary rudder, and attach the combined propeller and rudder, as shown. Storage batteries are placed on the floor of the boat, and connected by a twin flexible cable to the motor switch on the tiller handle. For ordinary pleasure boats a ½ H.P. motor is used, and in every case it runs on ball bearings, its spindle being vertical. The weight of this size of motor-rudder is only 35lb., and it is claimed that, with 20 storage cells of a suitable size, sufficient power can be obtained to drive a 16ft. sea dinghey with five passengers on board, at five



miles an hour for five hours. The 20-cell storage battery weighs about 180lb. As already mentioned, the apparatus is made in larger sizes, 5 H.P. being the maximum.

THE "BALLOT" SHAFT COUPLING AND PROPELLER.

The accompanying figure illustrates a novel system of shaft coupling, the invention of Mr. John Ballot. The coupling is adapted for fixing in position driving pulleys, flywheels, main shafts, screw propellers, and for many purposes where a coupling is required which is secure in every direction, and at the same time readily attachable and detachable. The shaft has formed upon it at the place where the pulley or flywheel is to be fixed three curved or cam-shaped projections, each of which extends in a helical longitudinal direction partly round the shaft. The one face of each of these projections is formed radial to the centre of the shaft, while the other face is formed with a curvature. The boss of the pulley or flywheel is, on the other hand, formed with three correspondingly shaped grooves or recesses extending in the same helical direction The projections and recesses consequently constitute an infinite series of a peculiar form of full and open screw threads of very steep or quick pitch, so that if the shaft be pushed longitudinally into the boss it will pass in with a screw motion. It will be found, however, that the longitudinal motion can at any point be arrested, if on holding the boss stationary there be applied more or less suddenly to the shaft a force in the circumferential direction, by which the curved surfaces of the projections will be firmly jammed or wedged against the corresponding curved surfaces of the recesses; and the frictional resistance to longitudinal motion produced by such jamming action will, with a sufficiently steep pitch of the screw, be greater than the force tending to produce a longitudinal motion. Thus, assuming the shaft to have been screwed into the boss of the pulley or flywheel until the helical projections of the former are situated entirely within the recesses of the latter, and the one part or the other then have a force applied to it in a circumferential direction so as to produce the before-mentioned jamming action, the pulley will be firmly fixed on the shaft for transmitting power when rotated by the shaft in that direction. If, on the other hand, a force be applied to the one or the other part in the contrary circumferential direction, the jam of the curved surfaces will be released, and as the radial surfaces of projections will then bear against the radial surfaces of the recesses, a screwing action will be produced, causing the pulley to be screwed longitudinally off the shaft. In order to enable the coupling to be employed for the transmission of rotary motion in either direction, longitudinal keyways are formed in the shaft and in the boss in such positions that



when the curved surfaces fit tightly against each other, as described, the grooves will be exactly opposite each other, so that keys can be inserted into them; but these keys will not be subject to the total strain exerted.

CORRESPONDENCE.

THE BRIGHTON BREAKDOWN.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: On looking through your issue of the 9th, I notice that Mr. Arnold Philip asks whether a pulsating current set up by an earthed armature has ever been actually observed. In one of the London supply stations some few years ago, an intermittent earth occurred on the armature of a direct-driven set, very much to the surprise of the attendant at a railway company's signal box in immediate proximity to the station, by the effect caused to their instruments. On shutting down the plant, the armature was tested, and no fault could be detected, but on revolving the machine an intermittent earth was found which put the armature to earth at every revolution. I know of several instances in direct-driven sets, where on an armature being short-circuited, the other units running in parallel have immediately dropped all their minimum cut-outs, entirely shutting down the station, and the cause was attributed to the dropping of the volts of the running machines and the fields ceasing to excite.—Yours, &c., INTERESTED.

London, Dec. 22, 1898.

Prof. Forbes' Power Transmission Schemes.—Prof. Forbes, writing in the *Journal* of the Society of Arts, gives two corrections to his recent Paper. The one is the fact, recently pointed out in our correspondence columns, that the copper-mortgage scheme was not new; the second is that the negotiations for the concession to utilise the water power of the Victoria Falls and Zambesi river were not dropped, but that a concession was actually granted to the African Concessions Syndicate in 1896.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *December 16, 1898.*

A Large Contract for Railway Equipment.—On December 15 the Third Avenue Railway Co. awarded to the Westinghouse Electric and Manufacturing Co. the contract for the complete steam and electric equipment for its entire street railway system. The Westinghouse Company will construct the steam engines, boilers and entire steam plant, besides the car equipment, the electric generators and all the electrical apparatus required. The total capacity of the station, which is located at 216th Street and Kingsbridge Road, in the upper part of this city, will be 64,000 H.P., and it is expected that the station will be one of the largest and most complete of its kind in the world. The entire equipment, which will be the most modern of all the lines operated by the railway company, will be supplied with power from this one station. Part of the electrical apparatus will be manufactured at the Pittsburg works of the Westinghouse Company and part at the works of the old Walker Company, in Cleveland. The engines will also be built at Pittsburg. It is stated that the new plant will be completed in about one year, and will involve an expenditure of between five and six million dollars. Work on the reconstruction of the roadbed on the Third Avenue line was commenced some weeks ago, and is rapidly being carried forward. It is too early yet to give further details regarding this interesting work. The company will instal 78·66 miles of electric conduit, of which at the present time 28·5 are being operated by cable power and 45·16 by horses. On the main Third Avenue line the present conduit will be utilised. The 125th Street and Tenth Avenue cable line will, however, be entirely reconstructed. The construction adopted for the new work differs radically from anything heretofore installed in America. The chief feature of novelty is in the employment under the track rails of a creosoted yellow pine longitudinal sleeper 5½in. wide and 6in. high laid in 30ft. lengths, the object of which is to secure an easy riding track. The yokes for the new construction are spaced 5ft. apart and are made up of three pieces riveted together, namely, a steel I-beam and two cast-iron side pieces. The yokes rest on a concrete bed 4in. in thickness. The track rail is laid in 60ft. lengths. It is 9in. high, and weighs about 107lb. to the yard. The insulators and conductors will be of the same type as those used by the Metropolitan Street Railway Co. in its conduit construction. The joints will be cast welded, and where the base of each rail rests on the yoke a spring is employed to give easy riding. It is estimated that 3,600 wheels pass over a given spot on this line in 24 hours.

An Electrical Exhibition Next Year.—The Electrical Exhibition Co., under whose auspices the electrical exhibition was held at Madison-square Garden in this city last May, will hold another exhibition at the same place during the same month next year, and all preliminary arrangements therefor have been completed. The show will be held under the auspices of, and in connection with, the twenty-second annual convention of the National Electric Light Association, which will be held in New York during the same month.

Electric Vehicles in a Snowstorm.—The recent severe snowstorm in this city gave the first opportunity for observing the behaviour, under trying climatic conditions, of the electric cabs and broughams now in operation in this city. To the surprise of even some of their most staunch upholders these vehicles gave better service through the trying night of November 26th than did horse-drawn vehicles. The cabs ran through the entire night, the last one coming in about six o'clock in the morning, at which time the snow had reached an average depth of about 8in., and much more where it had drifted. Other cab companies turned over orders to the electric service rather than fill them themselves. No very marked change in their running was noticed, although the mileage per charge of battery was, as a precautionary measure, greatly reduced, the vehicles being ordered in for fresh charges after covering 10 or 12 miles. The ease with which they ran was probably due to the large pneumatic tires, 5in. in diameter, which give a large bearing surface and reduce the tendency to cut deeply into the snow.

The Plans of the New Electric Light and Power Co.—The latest reports concerning the plans of the recently incorporated New York Gas, Electric Light, Heat and Power Co. are to the effect that it is negotiating to acquire the controlling interest in the various electric lighting companies in New York city and the Empire Subway Co., which controls all of the high-tension subways in Manhattan borough. It is stated that the new company, in order to obtain control of the subway company, has acquired an interest in the New York Telephone Co. This interest, it is stated, will enable the new company to use all the high-tension wires in the subways for light, heat and power purposes, the telephone company retaining the control of the low-tension subways for telephone purposes only. There is reason to believe that all of these reports have some foundation in fact, and it would not be surprising to find on January 1st next, all of the electric lighting interests in Manhattan and possibly in the entire city under one management. Everything points that way, and the truth of the above reports has been practically confirmed by those intimately connected with the enterprise.

THE USE OF ELECTRICITY IN THE SPANISH-AMERICAN WAR.*

BY THOS. G. GRIER.

The application of electricity in the army and navy for their various and many purposes is recent, but its progress is rapid. The object of this Paper is more to note the uses than to describe the details. The Fortification Board established ten years ago by the United States Government has developed complete and elaborate plans for the equipment of coast fortifications. In these plans electricity plays a very important part. Submarine mines connected by cable with harbour forts have been planted, electric light and power stations have been installed; search-lights, motors, telephones, telegraph instruments and many other devices have been used in preparing for the defence of our harbours. Range-finders for determining distances were extensively used; these instruments may be dependent upon electricity for their operation, as in the case of the Fiske range-finder, or may be operated mechanically. Just prior to our recent war with Spain 200 Lewis depression range-finders were ordered by the United States Government to equip our various fortifications. While these instruments are operated mechanically their efficiency in action depends upon the application of electricity in communicating the distance observed to the gun captain or commander.

To condense as much as possible, a brief summary of the applications can be given by describing the methods employed at Fort Wadsworth, which lies just below New York City. In this fort the fire commander directs the attack from a sheltered station equipped with a Lewis range-finder. There are also a position-finder station and four battery commander stations. The fire commander is in direct communication with all by means of telephones. In the position-finder's station, together with numerous other instruments, are a dial telegraph, electric clock and telephone. One of the guns is equipped with a dial telegraph, and another with a Sheehy teleotype, an instrument which indicates the azimuth or angle from a predetermined line, and gives the range or distance in yards the observed vessel is from the fort. All of the commanders' stations are, however, connected with the guns both by speaking tubes and telephones. Observations are signalled to the guns, and the course and speed of a ship are plotted upon a miniature representation of the harbour. By means of an electric clock placed at every station absolute uniformity of time is obtained, and the probable course and range of a vessel for several minutes can be plotted from these observations, and without even seeing the vessel the gun can be elevated for the range and trained for the proper angle, and by means of a stop watch the order to fire given so that the shot will fall upon the deck of a vessel whose course has been observed by men at a distance from the guns.

Fort Wadsworth has two 60,000 c.p. searchlights to sweep the harbour and guard against the approach of vessels on dark and stormy nights. An electric light and power plant forms a portion of the outfit, with a reserve storage battery to supplement the power station. The channel above the fort is mined, and should some of the vessels of a hostile fleet pass the guns of the fort the observer at the submarine station would be plotting the course of nearby ships, by means of range-finders or by information furnished him by the fort, and at the proper time fire the mine and sink the

* Abstract of a Paper read before the Chicago Electrical Association.

Digitized by Google

remnant of the fleet. The mining of the harbours was an important part of our coast defences, and the greatest demand for electrical wires and cables was for "torpedo cables" for use in submarine mines. It seems that our coast defence department has for years requested that an appropriation be made for cable, but the appropriations have been so cut down that not more than 5 per cent. of the amount needed was carried on hand by the Government. When war was declared, each of the manufacturers of submarine cable in this country received orders for all they could make in thirty days, and some were kept busy for 60 days, producing, probably, 200 miles of multiple cable and 200 miles of the single conductor. This has been distributed from the Bay of Fundy to Florida. Some was sent to the gulf cities, and some to California, Oregon and Washington. One hundred and fifty miles of each size was under contract in the early part of August.

There are three different kinds of mines used in our harbour defence:—(1) Observation mines, which are fired from shore when a ship is judged, by observation, to be within effective range of the explosive; (2) Automatic mines, which are self-firing on being struck by a vessel; (3) Electrical contact mines, which, on being struck by a ship, give notice on shore, and the operator, by the throw of a switch, fires the mines. The methods of firing observation mines and electrical contact mines are similar. Automatic mines may or may not be fired by electrical means. Mines may be placed upon the bottom of the harbour, and in such cases are called ground mines, and if they are contact mines the contact mechanism is contained in small buoys anchored at a depth below low-water mark just sufficient for them to be an obstruction in the path of vessels. When the channel is deep, buoyant or floating mines are used. A buoyant mine is more effective, as it lies nearer the object of attack, and for an equal effect does not require as large a charge of explosive.

Mines in Boston Harbour.—The shape and material of mines or mine cases are various, and the kinds employed at different points not always identical. However, a general description of the mines employed in Boston harbour will give a good idea of the plan and design used in all other harbours. There were about 1,000 mines planted in Boston harbour, covering the main ship channel and ingress to the harbour where vessels of over 12ft. draft could go at low water. The regular Government mine consists of an upright iron case about the shape of a top, with a strap on the bottom for holding the cable. Galvanised steel rope secured by an anchorage of any kind, in many cases of old horse-car rails, maintained the mines in position. The cable containing the electric wires runs up separately from the cable holding down the mines.

As the demand was urgent and no mines of the Government pattern were to be had, the engineers in Boston used new ale barrels, a hole being bored in one end for the receipt of the contact mechanism and cable. The barrels were encircled with rope to make a sling to hold them down, a flat steel ring being put around the rope so the steel anchor cable attached to it would not cut through. These mines were of different sizes and held from 100lb. to 500lb. of explosive gelatin. Ordinary dynamite was used in some mines where there was not enough gelatin to be obtained. This was put in through a small hole in the top where the electric contact mechanism is placed. The contact mechanism is connected through high resistance and by a battery circuit, using the cable and ground return for its conductors to an indicating and circuit closing device located in the protected casement on shore. When a ship strikes a mine containing the device, deflecting the mine from its normal position, the battery circuit is closed; this operates an indicating mechanism which closes a break in the dynamo circuit and notifies the operator. To throw on the current for exploding a mine it is necessary to throw in a switch or plug after the first break is closed by the indicating device. This circuit can be closed without any contact from the vessel at the will of the officer in the casement.

The firing switchboards at Boston contained an ordinary knife switch suitable for 500 volts, with springs which hold them open at all times except when held closed by the operator. These switches, one for each group of mines, were mounted on slate boards and plainly numbered with large letters. A dynamo developing one ampere at 500 volts, driven by an oil engine, furnished the exploding current. All of the parts of the contact mechanism were of platinum or gold-plated brass to prevent any possibility of corrosion. The exploder consisted of a thin strip of platinum wire which was laid in a case of fulminate, which in turn was put in a case of dry gun-cotton; the remainder of the explosive was wet.

The mines were usually placed in groups of seven each, about 150ft. apart. These groups of mines in Boston harbour were strung clear across the channel, and in the main there were three lines. In this method, should a vessel be sunk by the first line of mines and the wreck not obstruct the passage for other vessels, the second line of mines would catch the next vessel and the third line the third vessel. Between the mines were small casks with contact devices connected to mines on either side. These were cheaper than mines, but were equally serviceable and made the line complete, so that no vessel could get through.

Our army in the field has its cable tents completely equipped with telephones and telegraph instruments. The telephone at Santiago and adjacent points before and after the siege was of great service, and cable tents now have their names lengthened into the title of cable and telephone tents. The special cable, used in the signal service by General Greely, is very light and very strong, weighs about 60lb. to the mile, and is furnished on reels in half-mile lengths—a two-conductor concentric cable. This outpost cable, as it is called, is carried by a scout on a reel fastened to his back like a knapsack. He carries a telephone, and one end of the cable being connected at headquarters enables him to communicate in whispers to his commander. An attendant accompanies the scout with extra reels, which are easily attached when the wire on the first reel has reached its limit. Telephones, in fact, are used everywhere—in forts, in camps, in the field, and on boardvessels.

Among the most recent applications of electricity that found a place in the army and navy was the "X-ray" apparatus. It was used in the field, in the hospitals, and on the hospital ships.

Aboard modern men-of-war the electric light is found to be absolutely necessary for the efficiency of the ship. Searchlights are used to observe the movements of other vessels to find buoys or landmarks on entering shallow channels, to pick up disabled boats or men overboard, to make landings, and for signalling. The incandescent lamps illuminate the entire ship, dispensing with oil lamps and candles; they are also used for night signalling. Electric motors are used in hoisting boats and ammunition, for removing ashes, for steering, for training gun turrets and many other purposes. Steam whistles are opened and closed by electrically-operated valves. The range for guns and the speed and direction of revolving shafts are indicated by the electric current, and guns are fired by an electric spark. Telephones and electric signalling devices aboard ship are extensively used.

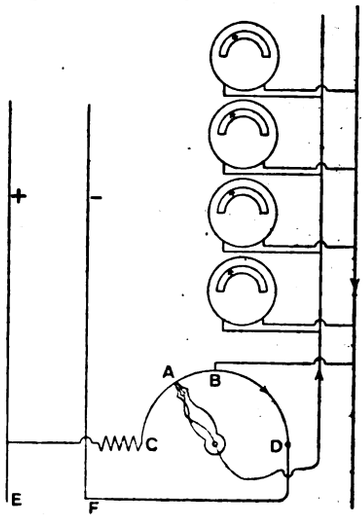

FIG. 1.—Principle of Helm Indicator.

This, in brief, covers the application of electricity ashore and afloat in the recent Spanish-American war. A description of the principles governing some of the signalling devices on board ship will materially assist in showing to what a great extent modern vessels depend upon electricity. The signalling and indicating devices used on vessels are: "helm indicators," "steering telegraphers," "speed indicator," "direction indicator," "range indicating system," "Fiske range finder," "azimuth telegraph" and "transmitter of orders." All of the devices consist of galvanometers, which indicate on their dials a difference of pressure, the dials being marked for the different offices the instruments perform, and with each instrument or system of instruments proper devices are used for altering resistances and consequently-changing pressures to accomplish the ends in view. A description of the principle applied to the helm indicator will explain the operation in general of all the others.

The object of the helm indicator is to indicate, at different parts of the ship, the position of the helm. The principle of operation is shown in Fig. 1. Attached to the helm and insulated from it is a metallic contact, A, which presses continually on an arc of resistance wire, C D. At the centre of this resistance wire is a permanent contact, B, which is connected by a wire to one side of a number of galvanometers located at various stations. E and F are the positive and negative wires of the electric lighting system. A dead resistance is inserted in the circuit connected with the arc of resistance wire C D, which reduces the current to about two

Digitized by Google

amperes. As the pointer A is moved toward the left, or toward C, the difference of pressure between A and B becomes greater and the flow of current through the galvanometer is greater. The galvanometers are adjusted so that they take the same angle as the helm, or pointer A. In Fig. 1, when the pointer is on the left of B, its pressure, as compared with B, is positive. When B and A are both in the centre, or when the pointer A coincides with the fixed point of contact B, then the needles of the galvanometers come to rest at zero or the centre of the scale. When A is moved toward the right, or toward D, then the conditions are reversed, A becomes negative compared with B, and the current flows in the opposite direction of the galvanometer, bringing the needle toward the right. One of the instruments can be on the bridge, one in the captain's cabin, one in the wheelhouse and one in the conning tower.

The steering telegraph is the same arrangement of galvanometers, with a device for altering the resistance by hand. The captain sets the resistance from his station, having an instrument before him. The same indication appears upon an instrument in the wheelhouse, and by noting the helm indicator the captain is advised when his order is obeyed. The same thing is true of the engine telegraph, the transmitter for orders and the azimuth telegraph.

In the Fiske range finder, the general principle is the measurement of the resistance of a conductor in the form of a Wheatstone bridge, there being two arcs of wire at the ends of a base line, corresponding to two contiguous members of the bridge. Two telescopes are located at the ends of the base line and carry contacts which move over the resistance wire as the telescopes are turned to be pointed upon any object. In Fig. 2 let the arms *a b* of a Wheat-

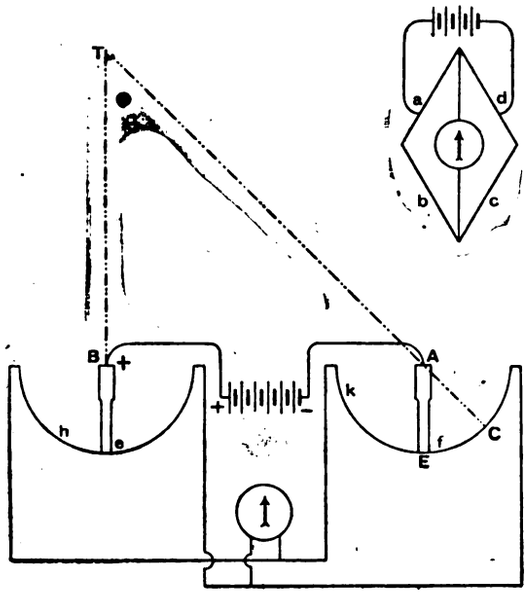

FIG. 2.—Principle of the Fiske Range Finder.

stone bridge be represented by arc *h*, while *c* and *d* are bent into arc *k*, both of these arcs being wires of conducting material. Let contacts *f* and *e* be attached to telescopes pivoted at A and B. When the telescopes are parallel, and when at right angles to the base line, the galvanometer will not deflect, and its point of rest is marked infinity. Now, let the telescopes converge and the angle of convergence is A T B, and presuming the telescope at B is pointing at right angles to the base line, the angle of convergence is measured by the arc C E. The bridge is out of balance—that is, the needle deflects, and the amount which it is out of balance will vary with the difference of position of the telescopes. The angles of convergence are not indicated upon the galvanometer or reading instrument, but the deflection of the needle is marked in yards.

The speed indicator is, in reality, a small alternating current dynamo, the current being great or small according to the speed of the shaft, and the strength of the current indicating upon an alternating-current galvanometer graduated in revolutions per minute. Six soft iron cores or inductors fastened to an iron ring on the shaft form the armature. These are rotated, the pole of a north and south magnet having two coils of wire at its extremities, the coils of wire being connected in series with the galvanometer.

The direction indicator simply tells in which direction the shaft is turning. A permanent magnet fastened to a ring on the shaft revolves in front of a soft iron bar, around which is a coil of wire that is connected to a galvanometer. The shaft revolving in one direction throws the pointer to one side, and when its direction is reversed throws it to the other side.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

NEW BOOKS AND EDITIONS.

The following New Books and Editions can be obtained of the Booksellers or direct from the Publishing Offices, 1, 2 and 3, Salisbury-court, Fleet-street, London :—

NOW READY.

"ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS."—By J. Elton Young, M.I.E.E. The scope of the book aims at furnishing a fuller treatment of the subject, from the standpoint of the Telegraph Engineer, than it has hitherto received, whilst it endeavours to facilitate a thorough comprehension of the theory of testing as applied to electrical lines in general. The Author hopes that, besides Telegraph and Telephone Engineers, it may, perhaps, also prove of service to those in charge of cables for the transmission of light and power. The localisation of faults has been very fully investigated, including the different degrees in which the various methods are affected by the presence of a second fault or of general leakage.—*Extract from Preface.* Demy 8vo, fully illustrated. 10s. 6d., post free; abroad 11s.

"SUBMARINE CABLE-LAYING AND REPAIRING."—By H. D. Wilkinson, M.I.E.E., &c., fully illustrated; price 12s. 6d.

"THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING."—A new work by Messrs. H. K. C. Fisher and J. C. H. Darby, with the above title, is now ready, price 6s. net; abroad, 6s. 3d. This work is intended to serve as a guide to operators already in the telegraph service, and to those who desire to enter that service. The great cable companies now insist that their operators and probationers shall pass certain examinations in electrical subjects. The book is very fully illustrated. *Second Edition now ready.*

"PRACTICAL NOTES FOR ELECTRICAL STUDENTS."—By Messrs. A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free.

"ELECTRO-CHEMISTRY."—By Dr. G. Gore. Third Edition. Price 2s., post free.

"ELECTRIC MOTIVE POWER," by Albion T. Snell, contains the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 280 illustrations. Price 10s. 6d., post free; abroad, 11s.

"WIRELESS TELEGRAPHY: SIGNALLING ACROSS SPACE WITHOUT WIRES BY ELECTRIC WAVES."—By Dr. O. J. Lodge, with many original illustrations. *Enlarged Edition*, 2s. 6d. net, 2s. 9d. post free.

"LABORATORY NOTES AND FORMS."—With the above title we have ready the New Edition of a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators and Students. The object of this series is the saving of the time of the Teacher and his Assistants, and to serve as a record of the work done by the Student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen net; in sets of any three, 1s. net; or the set of Twenty (Elementary or Advanced) Exercises can be obtained, price 5s. 6d. net. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. net; or in handy portfolio, price 12s. net; or bound in strong cloth case, price 12s. 6d. net. Strong portfolios can be had, price 1s. each.

NOW READY.—The cheaper edition of Dr. J. A. Fleming's "Electrical Laboratory Notes and Forms." These cheaper Forms have been prepared for the use of students and teachers at the Polytechnic and other science classes throughout the country. The demand for the original set of these Notes and Forms has led to a request for a cheaper set for use at the day and evening classes at many of the technical institutes. These new Forms, which differ only from the higher-priced set in being printed on smaller and cheaper paper and with less space for tabulated records, are issued at half the price of the original set.

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready. Price 7s. 6d.; abroad, 8s.

"THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS."—Edited and enlarged by W. Worby Beaumont. Price 3s. 6d., post free.

"THE ART OF ELECTROLYTIC SEPARATION OF METALS."—A second issue of Dr. Gore's book is now ready, price 10s. 6d., post free.

"THE MANUFACTURE OF ELECTRIC LIGHT CARBONS."—A Practical Guide to the establishment of a Carbon Manufactory. Fully illustrated. price 1s. 6d.; post free, 1s. 9d.

"THE BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH, 1896-97." A valuable, up-to-date compilation. Being an attempt to classify the data relating to X-Ray work. This work contains a quantity of general as well as special information bearing upon the whole subject of electrical discharge research. Price 5s., post free; abroad, 5s. 3d.

"LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS."—By F. C. Raphael. Price 5s., post free; abroad, 5s. 6d. Prospectus on application.

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book, by Messrs. W. Geipel and H. M. Kilgour; price 7s. 6d.; by post, 7s. 9d.; abroad, 8s. A fine large paper edition with wide margins for notes can also be supplied. Price 12s. 6d.; post free, 13s.; abroad, 13s. 6d. *New Edition in the press.*

"THE ALTERNATE CURRENT TRANSFORMER," Vol. I.—By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. *New Edition.* Price 12s. 6d., post free. Vol. II., price 12s. 6d. post free, is also ready.

"ELECTROMAGNETIC THEORY."—By Oliver Heaviside. Vol. I., price 12s. 6d.; post free, 13s.

"The Electrician" Electrical Trades' Directory and Handbook.—An important announcement in connection with the 1899 issue of the "Big Blue Book" will be found in an advertisement on another page of the present issue, to which our readers will please refer.

TENDERS INVITED.

The *Glasgow* Corporation invite tenders for providing and erecting generating plant at one or other of their new electricity works, including two 200 I.H.P., two 400 I.H.P., three 1,100 I.H.P. and two 2,200 I.H.P. engines, with dynamos and condensing plant. Copies of specification, &c., may be obtained from the city electrical engineer (Mr. W. A. Chamen), 75, Waterloo-street, and tenders must be lodged with the town clerk (Sir J. D. Marwick), City Chambers, Glasgow, by *Saturday, Jan. 21.* Some additional particulars are given in an advertisement.

As announced elsewhere, the *London* County Council invite tenders for the manufacture, delivery and erection complete of four continuous-current dynamos, one motor generator, two switchboards with switches, measuring instruments and other work required for the proposed Victoria Embankment electric generating station. Tenderers may, on and after Jan. 4, inspect the drawings and obtain specifications, &c., at the engineer's department, County Hall, Spring-gardens, S.W. Tenders, addressed to the clerk of the council (Mr. C. J. Stewart), must be sent to the County Hall, by 10 a.m., Jan. 31.

The *London* County Council also require tenders for the erection of four gas engines at the proposed Victoria Embankment electric generating station. Specifications, &c., from the engineer's department, Spring-gardens, S.W., and tenders to the clerk by 10 a.m., Jan. 31.

The Committee of Visitors of the *Cumberland* and *Westmoreland* Asylum invite tenders for the supply and erection of an electric tell-tale clock, with 30 stations. Tenders to the Committee, Garlands Asylum, Carlisle, not later than 2nd Jan.

The Corporation of *Burnley* invite tenders for the supply and delivery of underground cables. Tenders to Town Hall, Burnley, by Jan. 10.

The *Edinburgh* City Council require tenders for the supply of switchboards and boosters for their Macdonald-road electricity station. Tenders to Mr. Thomas Hunter, W.S., City Chambers, Edinburgh, by *Jan. 9, and not Jan. 2* as previously announced.

The Commissioners of the Burgh of *Stirling* invite tenders for the following :—(1) Lancashire boilers, with mechanical stokers ; (2) engines, dynamos, pumps, steam pipes, &c., Green's economiser and tools ; (3) storage batteries ; (4) switchboard and boosters ; and (5) arc lamps. Tenders to Mr. Thomas L. Galbraith by Jan. 2.

The *Barrow-in-Furness* Corporation require tenders for wiring the Free Library. Tenders to the Town Hall by noon of Jan. 20.

The Gas committee of the borough of *Rochdale* require tenders for the erection of electricity station buildings. Tenders to town clerk by Jan. 17.

The Municipality of *Merbes le Chateau*, Belgium, require tenders for the electric lighting of the streets. Particulars from le Bourgmestre.

The *Roumanian* Post and Telegraph authorities require tenders for the supply of 10,000 large, 15,000 medium, and 2,000 small porcelain insulators. Tenders by Jan. 16.

The *Shanghai* Council invite tenders for a concession, for a period of thirty years, for the exclusive right of establishing and working a telephone system in Shanghai. Particulars of Messrs. J. Pook and Co., 8, Jeffrey's-square, London, E.C. Tenders to Mr. J. O. P. Bland, Shanghai, by noon of March 31.

The *Shanghai* Council also invite tenders for a concession for constructing and working about 23 miles of electric tramways on the trolley system. Particulars from Messrs. John Pook and Co., 8, Jeffrey's-square, London, E.C. Tenders to Mr. J. O. P. Bland by noon of March 15, 1899.

TENDERS RECEIVED AND ACCEPTED.

The *London* School Board have received the following tenders for the supply of electrical plant to the training ship "Shaftesbury" :—

Generating Plant.

Electrical and General Engineering Co. (*recommended for acceptance*)	£785 0
Laing, Wharton and Down	1,080 0
Spagnoletti and Crookes	1,023 16
L. G. Tate	990 10
Wenham and Waters	980 10
Joel and Potter (United)	970 0
Woods and Co.	959 10
Drake and Gorham	933 10
Westminster Engineering Co.	880 0
Foote and Milne	871 0

Storage Battery.

Pritchetts and Gold (*recommended for acceptance*)	£152 2
Chloride Electrical Storage Syndicate	242 10
D.P. Battery Co.	222 0
Tudor Accumulator Co.	215 0
E.P.S. Co.	178 19

Pritchetts and Gold tendered for the annual maintenance at £13, the E.P.S. Co. at £35. 7s., the Chloride Syndicate at £20, and the Tudor Company at £18.

The *Great Northern Railway Co. of Ireland* have accepted the tender of Messrs. Victor Coates and Co. for the electric lighting of the station and offices at Amiens-street, Dublin. Messrs. Dobson and Curtis (Limited) also tendered.

All the tenders received by the *Braila* Municipal Council for the erection of electricity works in the town were from German firms.

APPOINTMENTS VACANT AND FILLED.

The London County Asylum, Bexley (Kent), require a working foreman engineer to take charge, under the asylum's engineer, of the engineering appliances, including heating, electric light, laundry and cooking. Salary £12. 10s. per month, and quarters. Forms of application from clerk to Asylums Committee (Mr. R. W. Partridge), 21, Whitehall Place, London, S.W., and must be in by Wednesday, Jan. 11.

The Urban District Council of St. Anne's-on-the-Sea, Lancs., invite applications for the appointment of electrical engineer to design and superintend the erection of an electricity supply station and the laying of mains, and to afterwards take charge. Commencing salary £170 a year, advancing to £200 and beyond, proportionally to the success of the undertaking. Applications to Mr. Thomas Bradley, clerk to the Council, by 5 p.m. of Jan. 2nd. See also an advertisement elsewhere.

The Corporation of Eccles require a switchboard attendant. Commencing salary £62 per annum. For further particulars see advertisement elsewhere. Applications to town clerk (Mr. George William Bailey), Town Hall, Eccles, by Tuesday, Jan. 3.

The St. Pancras (London) Guardians require an engineer with knowledge of electricity. Salary 50s. per week. Applications to Clerk, Vestry Hall, Pancras-road, N.W., by Jan. 2.

Mr. J. R. Blaikie has been appointed resident electrical engineer at the electricity works of the Newington (London) Vestry. Mr. Blaikie, who was selected out of 77 candidates, has for some time past been chief assistant at the Bristol Municipal electricity works.

BUSINESS NOTICE.

Mr. W. C. C. Hawtayne has removed to 9, Queen Street-place, London, E.C. The telegraphic address, "Hawtayne, London," and the telephone number, "5288 Bank," will remain the same as previously.

BANKRUPTCIES, LIQUIDATIONS, &c.

The meeting of the creditors of Lionel Riley, trading as L. V. Riley and Co., engineers and electricians, at various addresses in London, was held at the Guildhall Tavern, London, E.C., on Wednesday. The debtor estimated the net trade value of his stock at £135. 17s. 10d., and book debts reckoned as good at £175. 5s. 2d. The list of creditors are almost exclusively associated with the engineering trades, and the amounts are not very large. The debtor made an offer of 10s. in the £, to be paid in sums of 3s. in March, 3s. in June, and 4s. in September, the security for the payment being his own promissory note. A discussion ensued mainly upon the value of the guarantee, and dissatisfaction was expressed at the length of time asked for by the debtor, who subsequently agreed to reduce the period to six months. The meeting was adjourned to Jan. 4 to enable debtor to procure some more definite guarantee for the payment of the proposed composition. The failure is attributed to loss in equipping and opening works at Holloway, and "to a wrong system of pricing out prime costs, &c."

Creditors of the United Ordnance and Engineering Co. (Limited) must send particulars of their claims to the liquidator (Mr. W. E. Davies), Broad Sanctuary Chambers, Westminster, S.W., by Feb. 3.

The creditors of Thomas King, engineer, St. Peter-street, Maidstone, Kent, include :—

A. C. Hands	£174	Young and Marten	£19
Kemster and Co.	86	W. H. Willcox and Co.	18
Electrical Co.	85	Edison-Swan Co.	17
E. P. S. Co.	61	Woodall and Son	17
Robertsons and Co.	47	Fletcher, Russell and Co.	17
G. Farmiloe and Sons	40	J. Yates	16
Barry, Henry and Co.	36	Lambeth Brass and Iron Co.	15
Veritys (Limited)	32	National Telephone Co.	15
General Electric Co.	27	W. B. Haigh and Co.	15
J. Goldsmith	25	J. Smith and Sons	14
J. Miller and Co.	23	Siemens Bros. and Co.	13
Foster Bros.	22	Evered and Co.	12
Indiarubber Co.	21	Lumby, Son and Wood	11
Fieldings (Limited)	20	G. Braulik	10
J. B. Garnham	19	T. P. Cook and Co.	10
Hodges and Todd	19	John Russell and Co.	10
International Electric Co.	19	J. Hayward and Co.	10

The total liabilities are £2,497. 19s. 6d. (unsecured £2,103. 13s. 5d.), assets £1,109. 11s. 11d.

Digitized by Google

It has been resolved to wind up the Midland Motor Carriage Syndicate (Limited) voluntarily, and Mr. W. T. Smedley, 7, Newhall-street, Birmingham, has been appointed liquidator.

The application for the discharge in bankruptcy of W. R. Smith, electrical engineer, St. Andries, Hitherfield-road, Streatham, London, S.W., willbe heard on Jan. 16, at Wandsworth.

A first meeting of creditors of J. E. Liardet, engineer, 16, Hyde Park-gate, London, W., will take place on Jan. 6, and the public examination on Feb. 10, at Bankruptcy Buildings, London, W.C.

It has been resolved to wind up the B. C. Electric Syndicate (Limited) voluntarily, and to appoint Mr. A. E. M. Davis liquidator. Claims must be sent in to Mr. Davis, 1 and 2, Great Winchester-street, London, E.C., by Jan, 23.

Fixtures and Glassware Catalogue.—The ninth edition (1898-99) of the electrical fixtures and glasswork catalogue of the General Electric Company is to hand, and forms pages 551 to 838

FIG. 1.

of the company's main catalogue. From this mass of nearly 300 large quarto pages of text and illustrations it is difficult to select any particular items for special mention. The simple arrangement of the catalogue enables intending buyers to see at a glance what the company has to offer in each section of the book, and as the

FIG. 2.

illustrations are in the main direct photographs from the manufactured articles, and where this is not the case are guaranteed to be drawn direct from the originals. The General Electric Co. may be congratulated upon having done all that is possible to save the time of the contractor and to minimise the labour of their own supply departments. In Fig. 1 is shown a new arc lamp cradle and carrier made of wrought iron with copper cap to take a 14in. globe and to fit a 4in. spigot. This fitting is designed for the tops of lamp columns. Fig. 2 is a strong, well-made, watertight fitting suitable for street lighting, made up with a cast iron top, white enamelled inside, and a 15in. enamelled iron reflector. This fitting will carry one 100 c.p. or a group of three to five lamps and is constructed for a ½in. iron barrel. These are but two out of hundreds of illustrations in the catalogue, but we have said sufficient to induce those of our readers engaged in contracting work to obtain a copy of the catalogue. This is certainly one of the most complete and useful compendiums of electric light fittings and accessories ever offered to the trade. The General Electric Co. may be congratulated upon having brought their list up to a very high degree of excellence and completeness. We are promised shortly the full catalogue of the company's goods, of which the list under review forms an important part.

Telephone Apparatus.—Mr. G. A. Nussbaum has sent us his catalogue of the telephones and accessories made by the Société Industrielle des Téléphones, of which company he is sole agent in this country. One product of the Société's workshops is well known and very largely used in this country, viz., the Ader receiver. The catalogue is well illustrated, and a large number of instruments are described and priced. Among others we may mention a practical double head-gear receiver, which might be appreciated by electrophone users, and a neat military telephone set, which appears to supply all that is needed for military purposes in a very small compass.

Lead Seals.—Messrs. Marshall and Co. have sent us a price list and sample card of lead seals. These seals may be found useful for sealing standard electrical instruments, meters, and by electrical inspectors generally.

Seasonable Presents.—At a season of the year when gifts are especially the order of the day we make no apology for suggesting that few presents are more welcome than a good fountain pen; for, whether it be used for private or business purposes, it is one of the most convenient of pocket companions either a busy or an idle man can possess. Speaking of fountain pens brings us naturally to the firm which stands *par excellence* as pioneers of this class of trade, Messrs. Mabie, Todd and Bard, of 93, Cheapside, E.C., and 95, Regent-street, W., London, and Manchester, who have forwarded their latest list of "Swan" pens, specially designed for New Year's gifts. The Swan fountain pen is not only an ornamental present, but a very useful one, and as this make of a popular article is designed to meet the requirements of everyday use, it is safe from the annoyances of many so-called fountain pens. The fact that this particular type of pen is not made in low-priced qualities, and is yet the pen in most general use, is, to a considerable extent, a safeguard to users that they will, in buying a Swan pen, obtain a serviceable and reliable article. We can say from experience that the Swan pen is a useful travelling companion, and one which we should find some difficulty in replacing. It certainly forms a most acceptable present, and, as such, we commend it to those in doubt or difficulty as to what to buy. It can be sent to any destination by registered letter post.

Calendars, &c.—We have received for another year the pocket diary sent out by the Brush Company.

The Eastern and Eastern Extension Telegraph Companies have forwarded the usual handy paper-knife calendar and map of cable routes, which forms a highly useful adjunct to the desk and office.

We have to acknowledge the receipt of the much appreciated large-size blotting-pad and diary from the Electrical Power Storage Co. In addition to particulars of the E. P. S. accumulators, postal and other useful information is given.

There are to hand from the Accident Insurance Co. a hanging calendar, with monthly tear-off sheets and a small pocket calendar.

Exports of Electrical Apparatus and Material.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from Dec. 21 to Dec. 28, with the ports of destination:—

Argentina—Buenos Ayres, £2,059. *Australasia*—Adelaide, £500; Melbourne, £2,393; Sydney, £1,120. *Belgium*—Ostend, £7. *Canary Islands*—Las Palmas, £31. *Ceylon*—Colombo, £60. *China*—Shanghai, £145 (telegraph cable). *East Africa*—Mombasa, £23. *Egypt*—Alexandria, £86; Port Said, £30. *France*—Boulogne, £21; Marseilles, £18. *Germany*—Hamburg, £110. *Holland*—Amsterdam, £40; Flushing, £85. *Hong Kong*, £175. *India*—Bombay, £13; Calcutta, £384; Madras, £27. *Japan*—Nagasaki, £453; Yokohama, £813. *Malta*—£657. *Russia*—Libau, £100; Reval, £212 (telegraph material); St. Petersburg, £30. *South Africa*—Algoa Bay, £234; Cape Town, £289; Durban, £199; East London, £311; Port Elizabeth, £496. *Straits Settlements*—Penang, £107; Singapore, £61. *Sweden*—Gothenburg, £33. Total, £11,322 (for eight days) against £6,917 for three days last year (Dec. 22 to Dec. 24).

Digitized by Google

MUNICIPAL, FOREIGN AND GENERAL NOTES.

Asylum Lighting.—Messrs. Wallis-Jones and Dent have been appointed consulting engineers for the electric lighting, &c., of the Newport and Monmouthshire County Hospital.

Barmouth.—The Urban District Council have assented to the application of Mr. D. Davies for a provisional order for the town.

Birmingham.—The Corporation propose to introduce electric light into the Council House, at an estimated cost of about £2,000. The present gas fittings and pendants are to be adapted.

Buenos Aires.—The Municipality has sanctioned the transfer of the undertaking of the Metropolitan Tramway Co. to the German Electrical Company, which will equip the tram lines on the overhead trolley system. The City of Buenos Aires Electric Light and Power Co. has obtained the contract for supplying current to the Belgrano Electric Tramway Co. and the Anglo-Argentine Tramway Co. The lines of the latter company are to be converted to the overhead trolley system.

Croydon.—From March 25 the Town Council have decided to adopt the maximum demand system of charging for current, the first hour charge being 6d.

Dewsbury.—The Town Council have decided to construct electric tramways in this town at an estimated cost of £19,750. The scheme has been prepared by the electrical engineer (Mr. O. M. Jonas)

Electric Power Schemes.—The local authorities of the towns in Lancashire and Cheshire affected by the proposed schemes for the supply of electricity "in bulk" are already organising opposition to the bills to be presented to Parliament in the ensuing session. A meeting has been called for Jan. 10 by the Lord Mayor of Manchester to decide upon a course of action.

Electrical Progress in Brazil.—According to the recent report of a travelling representative of the Philadelphia Commercial Museum "the electrical goods trade of Brazil is growing by leaps and bounds," as a few years ago electric lighting, traction, power, &c., were unknown. Now nearly every place within 300 miles of the coast is either lighted electrically or the subject is under consideration. Many of the mining companies and mills in the interior have light and power plants in operation, several of the large plants having been shipped by British firms. Imports of electrical plant and apparatus are large and constantly growing, and the supplies are controlled almost exclusively by English and Belgian firms, but American houses execute a fair share of the orders for electrical machinery. Arc and incandescent lamps, fittings, carbons, cables, electric bells, batteries, &c., are in demand in the districts along the line of the Central Railroad, between Rio and Sao Paulo and Rio and Bello Horizonte. This latter city is the new capital of the State of Minas Geraes, and is a growing city of nearly 30,000 inhabitants. The towns of Sabara, Sete Lagoas, Curvello, Caethe, Ouro Preto, La Fayette, and about 10 other small towns are lighted electrically. The report states that: "At Juiz de Fora there is an electrical plant installed, and an agency in that town for sundries would do well in supplying not only Juiz de Fora and the adjoining town of Marianna Procopio, but also the towns on the lines of the west of the Minas and Leopoldina Railroads. Along the line from Rio to Sao Paulo are also many towns in which it might be advantageous to have agents. A competent salesman, familiar with the Portuguese language, travelling through this section, could do wonders in the way of securing orders and appointing responsible agents. This may also be said of nearly all the interior cities, as attention, so far, has seemingly been paid only to the large cities on the coast, and even there not to the extent the trade possibilities deserve."

Epsom.—Electricity supply works are to be erected by the District Council, and tenders are to be invited for supply of plant.

Glasgow.—The Tramways committee, on Wednesday, adopted the recommendation of its sub-committee that the present tramway system should be converted to the overhead trolley system as soon as possible. The entire conversion is planned to be completed by 1901.

Govan.—Owing to the National Telephone Co. having made arrangements with the Town Council for placing its wires underground, the company proposes to open a telephone exchange on the twin-wire system within the Burgh in connection with the company's Glasgow system.

Huddersfield.—There are at present 781 customers of the electricity department, and the equivalent number of 8 c.p. lamps connected is 52,784. The increase in the electrical undertaking has resulted in a rise in the assessment from £750 in 1894 to £1,800.

Kingston-on-Thames.—The General Purposes committee of the Town Council are considering the proposals of the Drake and Gorham Electric Power and Traction Syndicate to construct electric tramways in the district on the overhead trolley system. A company, with a capital of £100,000, would be formed to carry out the work, and electric current would be taken from the Corporation electricity works.

London Underground Electric Railways.—The following bills relating to London underground electric railways have been deposited at the Private Bill Office:—

Great Northern and Strand Railway Bill to incorporate a company to construct an underground railway from Wood Green to the Strand. The line to be worked by electricity or other motive power not being steam. The proposed capital is £2,400,000, in £10 shares, with borrowing powers up to £800,000. The promoters include the Right Hon. W. L. Jackson, Sir Andrew Fairburn, Mr. L. C. Probyn and Sir Henry Oakley, who are named as first Directors.

The North-West London Railway Bill to incorporate a company to construct an underground railway from the Marble Arch to Cricklewood, to be worked by electric power. The proposed capital is £1,750,000 and borrowing powers. The first Directors include Sir Robert Head, the Hon. C. M. Knatchbull-Hugessen, Mr. N. S. Russell and Mr. J. S. Brookfield.

The Central London Railway Bill seeks an extension of time for the completion of that railway.

Newcastle (New South Wales).—The Municipal Council received six tenders for the erection of electricity supply works, the tenderers being Messrs. Edge and Edge; Gibson, Battle and Co.; R. Thompson; Morrison and Cearby; Rodgers Bros., and the Brush Company. Mr. R. Thompson offered to erect the building and supply the necessary plant and apparatus for an aggregate sum of £8,499. 16s. The tenders are at present under the consideration of the consulting engineer (Mr. Norman Selfe).

St. Olave's (London).—The District Board of Works have authorised the London Electric Supply Corporation to lay distributing mains in Stoney-lane and low-tension distributing mains in Duke-street and Tooley-street.

St. Pancras (London).—The Workhouse Infirmary, Dartmouth Park, is to be lighted electrically.

S. A. R. Telegraphs.—The total receipts from the telegraph and telephone services for nine months to Sept. 30 last have been £69,546, against £71,319 for the same period of 1897. The telegraph service shows a decrease of £3,918, and the telephone service an increase of £2,145. 20,085 cablegrams, value £50,473, were sent, against 23,300, value £55,934, in 1897.

Southampton.—Major P. Cardew held an inquiry last week into the circumstances connected with the fatal accident to Walter Day, an electrical jointer in the employment of Messrs. W. T. Glover and Co., who was killed on the 12th inst. while engaged in jointing a cable. After the town clerk had narrated the facts of the case Mr. J. Brooking, electrical engineer and manager for Messrs. Glover and Co. in Southampton, gave evidence and stated that they had been working day and night to get the mains ready. Since the accident the joints had been taped over. He had traced back the cable to what he imagined to be the low-tension pipe. The two pipes, high and low tension, were nearly alike, and there was no external mark to tell which was the high-tension pipe. Had he known the leakage was in the high tension cable he would not have allowed Day to repair it without first having the current switched off. He did not remember having made temporary joints on a high tension cable before. He mentioned to Mr. Shepherd (clerk of the works) that he did not like putting in a temporary joint, but, on being pressed, he thought it better to do so. He was aware of the Board of Trade regulations, and did not think that they were strictly adhered to in this case. It was possible to make a temporary joint as safe as a permanent one, but only by using extra thicknesses. He had the joints made, as he thought, very safe, and had extra material, although not so much as he thought. Mr. John Shepherd (clerk of the works for the laying of the mains) stated that when he was told of the leakage he was apprehensive of danger. He had seen the joints made, and was satisfied with them. Mr. F. H. Chaplin, borough electrical engineer, believed that an undertaking had been given to supply current to several consumers on the 7th inst. Owing to this need temporary joints were made in that particular box and two others. There was a current of above 2,000 volts going through the high-tension cable on the day of the accident. He held the opinion that the reason of the joint being forced against the brickwork was owing to the vibration from the railway tunnel underneath. The current was complete as far as it went, and he tested the high-tension cable with a current of 2,300 volts. He thought that when the box was complete the joints would be secure. Mr. E. Manville, consulting engineer to the Corporation, said, in reply to a question from the inspector, that the work was very much behindhand, and the Corporation had pressed the contractors to complete it, and no doubt it was due to the non-completion of the work that the temporary joints were made. Although they were temporary joints, they ought to have been fit for the work they were to do. He maintained that if they had had proper metallic shielding an accident of that sort could not have resulted. Major Cardew will present his report in due course.

West Ham.—The applications for electric current have been so promising that the Town Council have decided, on the recommendation of the borough electrical engineer (Mr. J. J. Steinitz), to put down two additional 800 kilowatt steam alternators, and to carry out other extensions of the electricity works, which will increase the capacity of the station to the equivalent of 80,000 8 c.p. lamps connected. The total estimated cost of the extension is £47,600, for which borrowing powers are to be sought from the Local Government Board.

Weston-super-Mare.—At a special meeting of the District Council on Wednesday the agreement for the transfer of the Weston-super-Mare provisional order to the Electrical Power Distribution Co. was approved.

Wrexham.—There is, after all a probability that the scheme for the construction of electric tramways in this town will receive the sanction of the Town Council, as the General Purposes committee have withdrawn their report recommending the Council to oppose the scheme, the Chairman of the committee intimating at the same time that some of the members had altered their minds on the subject. The Lighting committee are collecting information as to the desirability of establishing electricity works.

COMPANIES' MEETINGS AND REPORTS.

Smithfield Markets Electric Supply Co. (Limited).

The first ordinary general meeting of this Company was held on the 23rd inst., under the presidency of Mr. J. BROWNE MARTIN.

The SECRETARY (Mr. G. M. Powell) read the notice calling the meeting.

The CHAIRMAN, in moving the adoption of the report, said it would be known to the majority present that about a year ago their Company purchased the undertaking called the Smithfield Electric Construction Co. When they came into possession they found that the machinery and other appliances connected with it had had a good deal of wear, and had not been kept up to date. They therefore at once proceeded to set matters straight, and employed the services of an eminent engineer, Mr. Cooper. Acting upon that gentleman's advice they overhauled all the machinery and, where necessary, supplemented it with other machinery, and also decided to put in accumulators which would effect a saving of about £500 a year. Nearly every shop in the new fish market had now been connected, and they had received instructions from the Corporation for the lighting of the old fish market, which would be re-opened as a meat market early next year. This would considerably increase the output of their Company. He might mention that when they first took over the business an arrangement was in existence to supply electricity on what was termed the "lump sum" system—that was, that any customer who was willing to pay a certain "lump sum" per annum had electricity supplied to him, whether a large or small quantity, for that sum. He thought it would appeal to everyone that in such circumstances as these there would not be the care and supervision in using electricity which consumers would exercise when they had to pay by meter. The Directors, therefore, decided that they must in future supply in the ordinary way, by meter. In making a change there was always a great deal of criticism, and, with all their care, attention and courtesy they lost a very large number of customers at the outset, but those who left them had not only returned but in several cases had induced others, who were not on previously, to take current. The shareholders were aware that the Directors had applied for several Provisional Orders, and he felt there was no doubt that they stood a very fair chance of getting one or more of them. He thought it must appeal to the citizens of London that if there was to be a second company introduced into the City, their Company should get the preference over any other. They were the only company, excepting the City of London Electric Co., which held any Provisional Order from the City. He thought it right to inform them that they were also applying to the Holborn and St. Luke's districts, which were both exceedingly valuable electric lighting areas. His colleague and himself were very confident that their company would ultimately be of very much larger dimensions than it was now. They were neither of them new to the electric lighting industry, and the companies which he was connected with, which began in a very small way, were now very large and paying well. The Directors would like to tell them a good deal more but in the interests of the Company it was not advisable "to give the show away." He concluded by moving the adoption of the report and accounts.

Mr. ERNEST SCHENK seconded the motion.

The CHAIRMAN, in answer to a question, stated that they had a very much larger plant than was required for present purposes, and they were quite able to supply a largely increased quantity of current without any additional capital.

Mr. EDENSOR asked whether it would be possible to give the shareholders some information how a prospective profit of £3,750 had been turned into a loss of about £700.

The CHAIRMAN stated that it was not a loss of £700.

Mr. EDENSOR said that after paying the debenture interest there was a loss, if not of £700, yet of several hundred pounds.

The CHAIRMAN said that this was all explained by what he had referred to—the change in the system of charges. They were obliged to make this alteration, or they would simply have dwindled on without making any way. He saw no reason why their Company should work on any different lines to those of other companies. They were supplying current at, he believed, less than any other company, but they could see that even at this price they could make an ample profit.

Mr. EDENSOR said he thought the explanation was satisfactory, but he considered it rather misleading to mention an estimated profit of £3,750 without first finding out whether the machinery was antiquated and a proper one to work with.

The CHAIRMAN said that he had not stated that the system was antiquated; he had meant to say that it was in bad order.

Mr. EDENSOR asked whether this could not have been found out first.

The CHAIRMAN replied that if machinery was kept bright and clean it was very difficult to find out until it was worked for some time whether it had been properly used or not. The Directors took all the precautions possible to find out these things; they took the best expert opinion they could get, but until they had positively worked the machinery, they could not find out that a great many of the bearings and other things required alteration. It was only through the efforts of Mr. Cooper (the consulting engineer) that they ultimately located the defects. In working machinery, particularly like theirs, there was very great wear and tear unless everything was true, and they found that it was of no use to patch things.

Mr. V. B. D. COOPER stated that the defects in the machinery to which the Chairman had referred were chiefly that the arrangements of the plant were not such as suited the particular load and the particular hours during which their load was employed; they were not so much inherent defects in the machinery itself. If they had had a more continuous load than they found they had the machinery would have been much more adapted to it. The changes made would be productive of economy and be more suited to the work they had to do. The storage battery about to be erected would be far more economical. Another alteration they had made had reference particularly to the distribution of the load, and would also be more economical.

Mr. EDENSOR said it seemed to him that the Directors had been misled, and that they had made statements in the prospectus leading those who read it to believe that they were getting a good working concern giving a certain amount of profit. The explanation just made had, however, proved to him that the thing was not in a condition in which it ought to have been brought before the public. He also wished to know how many shops were now connected.

The CHAIRMAN replied that he would rather not answer the question.

Mr. EDENSOR said that he saw no harm in the information being given. The prospectus stated that 175 shops were connected at that time.

Mr. COOPER pointed out, with reference to the last speaker's remark, that his (Mr. Cooper's) explanation had led him to suppose that the Directors were misled, that the change in their load was due to the policy which was considered necessary of insisting on supplying every customer at a remunerative price. If the load had remained the same as it was when they took the concern over the machinery would have been just the thing for it; but when they found that it was desirable to discontinue supplying those people who were using the light by contract, and in a very wasteful manner, it was necessary to make the changes he had alluded to.

Mr. WHITEHEAD inquired whether the Directors maintained their belief in the fairness of Messrs. Fuller, Horsey and Co.'s valuation of £86,566 for the going concern turned over to this Company. He also wished to know what portion of the £86,000 odd was goodwill, and whether the Directors would in future balance-sheets show this item separately. Their Company had only 15 years' concession, at the end of which he believed the Corporation had the right to take over the plant. Anything in the shape of goodwill they had paid for would then become valueless; and it seemed to him, therefore, that they ought to write off a large portion of this goodwill, or at the end of the concession their £5 shares might be worth only £2.10s. He noticed in the prospectus that there were two estimates of the cost of current, one being 3½d. and the other 3⅜d. He wished to know whether they were working at this cost. Was the sum to be received from the cold air store company likely to reach £2,500, as stated in the prospectus? Did the £5,788 which they received by the sale of current for the year ended September 30th last include the value of the current supplied to the cold air store company? Was the cold air store company a public or private one?

Mr. PROUD said that he was induced to subscribe to the company on the faith of the statements in the prospectus. If he were not mistaken, he believed the prospectus contained a statement that the Company made a large profit from supplying electricity by contract, and that that profit would enable them to pay a dividend of something over 4 per cent. He wanted to know who was responsible for issuing a misleading prospectus, as he regarded it, which led him to become a shareholder in a company whose shares he could scarcely sell. He maintained that the promoter of the company, and those who supported him, should be made to disgorge.

Mr. SCHENK (a Director) said the Chairman had asked him to reply. The Chairman had asked that the question as to the number of shops connected might not be pressed. They had nothing to be afraid of, and personally he would not mind publishing the fact. The shareholders would be glad to hear that they had substantially more customers on now than on the day the prospectus was published. As the result of the changes they had found it necessary to make, they had lost a large number of customers, and they ran the station for at least six months at a loss and they had to do so. As a result, however, of having faced the difficulty they were now running at a substantial profit. One shareholder had stated quite erroneously—no doubt, he was mistaken—that a statement was made in the prospectus that they were making a large profit by the sale of electricity by contract. No such statement, however, was made in

Digitized by Google

the prospectus. He thought that they had had to pay for mismanagement in the past; they received no complaints now. They never said in the prospectus—for which as Directors they were responsible, as they had to sign it—that they were making a profit on contracts. They stated in the prospectus that on the basis of contract sales for the previous nine months, they were selling at that time (the time the prospectus was published) something like 800,000 units a year, and they estimated a reduction down to 600,000 units a year as the result of adopting the meter system. He would not mention exactly the number of units sold in the year, but it was less than that. He might, however, say that the figures for the present quarter showed that the estimate of 600,000 units a year on which the 4½ per cent. was based was almost precisely borne out. He had not anticipated anything in the nature of a strike among their consumers, who were only asked to pay the Company what they were now paying, which they were satisfied to pay, and what was actually the lowest price charged by any other electric lighting company in London. It was only by comparison with their previously absurdly low rate that the altered price looked high. As to the question whether the estimate of the cost of production given in the prospectus had been borne out, he ought first to explain that they had two or three conditions to deal with in making up their accounts which no other company in London was affected by. In the first place they had to make a present to the Corporation of 50,000 units a year for lighting the avenues of the market.

A SHAREHOLDER: That is not stated in the prospectus.

Mr. SCHENK, continuing, said that he did not think that it was material; they could quite well afford to do it, but it was a point to be borne in mind in making up the price of the unit. The Company also maintained the customers' installations free. The total cost per unit supplied for the whole of the twelve months to September, 1898, was 3·37d., of which market maintenance, &c., would account for the ·37d. It therefore came out that their total cost for the last twelve months had been 3d. per unit. The cost in the case of the Notting Hill Co. (and figures were not particularly interesting unless they were comparative)—whose output might reasonably be compared to their own, and whose shares stood at a very good premium—was for that year 3·12d. In the present quarter—the December quarter—when they were themselves making up for lost ground, he was able to inform them that their cost of production—making allowance for the lamps and the maintenance of the market—was positively less than that of any other company in London, and was less, of course, than the estimate given in the prospectus. He said this with the more satisfaction in view of the remark of one of the shareholders who had wanted to sell his shares. If they could only produce their electricity at less than any other company in London there could not be very much mismanagement. The Directors had been asked whether they maintained their belief in Messrs. Fuller, Horsey and Co.'s valuation of £86,000 odd, and how much of it was goodwill. Now that they had had twelve months' experience he had greater confidence than when he signed the prospectus that the property was worth the £86,000 odd as a going concern.

Mr. EDENSOR said he thought that this statement was quite satisfactory.

Mr. SCHENK, in further reply, stated that their revenue did not include anything from the cold store excepting £575, which they received for the first instalment of one quarter of that year; there was nothing to pay for the previous nine months. At the present time he thought that the Cold Storage Co. might be described as private; but in due course he thought it would be public; but the people behind it were sufficiently well known and substantial for this Company's purposes. He had no hesitation in saying that they would be able to pay a dividend on the ordinary shares next year; he believed that they would be able to do so out of their ordinary business alone, but they had certain developments on hand. If they got the Provisional Orders to which reference had been made, they would require to raise a large sum of money, and he might state that whatever price their shares might stand at the whole of the money they required would be forthcoming.

The motion was carried, and a vote of thanks to the Chairman and Directors terminated the meeting.

Automatic Telephone Co. (Limited).

The annual general meeting of this Company was held on Friday last. Mr. MAX MARGOWSKI presided.

At the outset Mr. J. D. GIBBS stated that it was incumbent upon him to make some explanation with regard to the action that he took against some of his co-Directors. Owing to the fact that certain sums were due to the consulting engineer, Mr. Gustave Selegmann-Lui, for salary and for patents, he thought there ought to be sufficient money in the coffers of the Company to meet such demands. However, the money was not there, because the signatories to the memorandum and articles of association considered they were not bound to pay up the 3s. a share which other shareholders had paid. The speaker joined Mr. Alexander in commencing proceedings to ascertain whether signatories were not bound to pay the 3s., which would put the Company into a position enabling them to discharge all their liabilities. The proceedings had not yet led to any result. He was unwilling to say anything which would cause bitterness amongst the shareholders towards the Directors.

Mr. ALEXANDER (another Director) also spoke, emphasising the statement that when the books were laid open to their inspection they found that the signatories' shares were not paid.

The CHAIRMAN, in a long speech, which was frequently interrupted, observed that the new Company had been formed, not for the purpose of watering the capital or increasing the number of shareholders, but with the object of securing the services of Mr. Seligmann-Lui. An agreement was arrived at, under which it was stipulated that no public issue should be made, but that all the subscriptions should come from the shareholders, and unless £10,000 was subscribed Mr. Seligmann-Lui would not join the Company. However, he (the Chairman) secured this gentleman's services. He was sorry to say that the shareholders subscribed to the amount of only 9,000 shares at 5s. each. Furthermore, the Company had a liability of £2,000. In order to carry the scheme through, he, as Managing Director, became responsible for no less than 34,900 shares. Out of the £10,000 he became responsible for £8,000. He had subscribed to the Syndicate 98 per cent. of the working capital and now he held 80 per cent. in the new company. Having become responsible for so large an amount, he had a clause inserted in the articles that not more than 1s. a share should be called up. In these circumstances he had found it necessary to form a "pool." He then went on to refer to the friction on the Board, and finally moved the adoption of the report.

For something like an hour there was a scene of the wildest disorder, shareholders putting to the Chairman innumerable questions. Amid the disorder it was impossible to follow the speakers.

Eventually an amendment for the adjournment of the meeting to February 1st next was carried by an overwhelming majority.

The CHAIRMAN demanded a poll, and with much vehemence expressed his intention of proceeding with the meeting.

Shareholders contended that no poll on a mere adjournment could be taken, and the great body of the proprietors then left the room.

NEW COMPANIES, STATUTORY RETURNS, &c.

A.B.C. ELECTRIC ARC LAMP AND INCANDESCENT MANTLE CO. (LIMITED).—This company was registered on Dec. 19, with a capital of £60,000, in £1 shares, to enter into an agreement with F. Fanta for the acquisition of certain patents and patent rights relating to improvements in electrical apparatus, and to develop and turn to account same, manufacturers of and dealers in electrical apparatus of every description, and also as engineers, machinists, motor-car builders, &c.

ABERDEEN ELECTRICAL CO. (LIMITED).—This company was registered in Edinburgh on Dec. 21 with a capital of £10,000, in £1 shares, to acquire, take over as a going concern, and carry on the business of an electrical engineer now carried on by Richard G. Botting. The first subscribers are: J. Edwards, G. England, G. Rainst, J. McBain, W. Ironside, Alex. Ledingham and R. G. Botting (engineer). The first Directors are: J. Edwards, G. England, W. Ironside and Alex. Ledingham.

BUCK AND CO. (LIMITED).—This company was registered on Dec. 20 with a capital of £2,000, in £1 shares (of which 1,000 are £5 per cent. Cumulative Preference), to carry on the business of electricians, electrical, mechanical and metallurgical engineers, suppliers of electricity, founders and smiths, cycle and motor-car builders and designers, electro-platers, &c. The first subscribers, with one share each, are: H. T. Underwood, J. H. Bailey, W. R. Whitehead, W. G. Brown, Mrs. C. J. Buck, E. A. Hill (electrical engineer), and Albert G. R. Buck (electrical engineer). The first Directors are: H. T. Underwood and Albert G. R. Buck.

HART ACCUMULATOR CO. (LIMITED).—This company was registered on Dec. 23 with a capital of £40,000, in £1 shares, to acquire and take over the business now carried on by the Hart Secondary Battery Syndicate (Limited), to enter into an agreement with the Hart Secondary Battery Syndicate (Limited), S. W. Hart and E. J. Clark, and to carry on the business of electricians, electrical and mechanical engineers, and the general business of an electric lighting, heating and power company. The first subscribers are: Samuel W. Hart, G. A. Bacon, J. G. Abraham, G. B. Kidd, L. W. Spratt, G. Hay and E. H. White.

KIDDERMINSTER AND DISTRICT ELECTRIC LIGHTING AND TRACTION CO. (LIMITED).—This company has been registered with a capital of £100,000, in £10 shares (5,000 Preference) to carry on the business of electrical engineers and contractors, electricians, suppliers of electricity, manufacturers of electrical apparatus, mechanical and chemical engineers, tramway and light railway proprietors, carriers of passengers and goods, &c., and to generate, produce, and supply electric light, heat, &c. The subscribers are:—Emile Garcke, George Stevens, Charles H. Dade, Charles H. Gadsby, W. Howard Smith (engineer), C. Walmsley, and Henry M. Sayers (engineer).

PEARSON FIRE ALARM SYSTEM (LIMITED).—This company has been registered with a capital of £150,000, in £1 shares, to acquire the benefit of three inventions, known respectively as the Pearson Automatic Fire Indicator, the Pearson Automatic Box Telegraph Fire Alarm Apparatus and the Pearson Automatic Railway Signal, and to carry on business as manufacturers of fire inductors, fire extinguishers, fire engines, &c. The first directors are Hon. L. Holland, H. Gamman and R. Pearson.

ALLIANCE ELECTRICAL CO. (LIMITED).—The statutory return, to Oct. 27, has been filed. The capital is £1,000, in £1 shares, of which seven have been taken up and paid for in full.

CRYSTAL ELECTRIC LAMP AND ROSE AND BIRD (LIMITED).—The statutory return, to Nov. 24, has been filed. The capital is £50,000, in £1 shares (of which 10,000 are Preference). 39,750 Ordinary and 6,000 Preference have been taken up, and 39,743 of the former and 1,000 of the latter have been issued as fully paid. The full amount has been called on the remainder.

Digitized by Google

CITY NOTES.

MEMORANDA.—Bank rate 4 per cent. (since Oct. 13, 1898). Price of silver 27⅞d. per oz. (Dec. 23). Consols (2¾ per cent.) 110⅛—110⅝ for money, 110⅝—110¾ for account; 2½ per cent. 104—104¼ (Dec. 22). Stock Exchange Settling Days: Stocks and Shares Continuation Day, Jan. 11; Ticket Day, Jan. 12; Pay Day, Jan. 13; Mining Share Carry-over Day, Jan. 10.

AMAZON TELEGRAPH CO. (LIMITED).—The coupons due 31st inst. of the £122,400 Five per Cent. Debentures will be paid by Messrs. Barclay and Co., 54, Lombard-street, E.C.

CAPE ELECTRIC TRAMWAYS (LIMITED).—An interim dividend of 3 per cent., free of income-tax, has been declared payable to all shareholders on the register on the 31st inst., and to holders of Coupon No. 3 attached to share warrants to bearer. The transfer register will be closed from the 2nd to the 7th Jan. inclusive.

DOUGLAS SOUTHERN ELECTRIC TRAMWAYS (LIMITED).—The annual meeting of this company was held on Tuesday. The Chairman (Mr. J. T. Hutchinson) moved the adoption of the report, which stated that during the last season of 132 days, 40,963 miles were run, 94,173 passengers were carried, and the total receipts were £4,135. 15s. 2d., from which £689. 5s. 10d. was paid to the Marine Drive for tolls. The whole of the promotion expenses (£600) had been written off, and £300 had been paid to the Douglas Head Marine Drive Co. as damages for failure to complete the line in 1896. £302 odd had been spent on the permanent way. These three extraordinary items reduced the profit on the year to £90. 13s. 2d., which brought the balance in hand up to £350. 19s. 7d. Although no dividend could be recommended on the subscribed capital of £41,045, the Directors hoped that, with a fine season, next year would be a profitable one.

ELECTRIC CONSTRUCTION CO. (LIMITED).—The holders of this company's Six per Cent. Second Mortgage Debentures agreed on the 21st inst. to accept an offer to pay off the debentures on Jan. 1.

KELVINSIDE ELECTRICITY CO. (LIMITED).—The ordinary general meeting of this company was held at Glasgow on Wednesday. The Chairman (Mr. J. Reid) moved the adoption of the report, and said the past year had been one of increased activity, and the Directors were glad to be able to report that the district of Kelvinside which their order covered had awakened to the desirability of having the electric light introduced. The number of consumers had increased 45 per cent., and, though the full benefit had not yet been felt of those lately added to the number, the revenue of the company would soon feel the addition. Last year they were supplying a considerable amount of electricity for power and heat, the contract for which terminated last year, and that circumstance made the increase in consumption rather less than might have been expected. The works costs continued to show the same very low proportion. The Directors were glad to be able to say that the company had now turned the corner. A small profit on the year's working was shown by the accounts, and they felt confident this would be largely increased as the company proceeded. In the report reference was made to the question of their negotiations with the Glasgow Corporation for the sale of the undertaking, and the shareholders could rely upon the Directors carefully safeguarding their interests. In the event of negotiations not coming to a satisfactory conclusion, they could confidently look forward to the undertaking being a highly remunerative one. Lord Kelvin said he had a strong feeling that they had a valuable property in the generating station and the underground conductors, and there was reason to expect that with the great increase of population in the district, and the number of new houses of the best class that were being erected, in respect to the consumption of electricity for light, the future of the company would be very good, and that although up till now profits had not been earned, they had every prospect of a large dividend-paying business. He had visited the station, and anyone could see that there was space for a great deal more machinery, and for doing more remunerative work than was being done. They had a slight balance this year on the right side, and he believed the state of things would be different in the course of a few years. And he for one would prefer to wait five or 10 years, or whatever time was necessary, for the full development of the profit-earning capacity of the company, to parting with it unless on terms of a throughly satisfactory character. They had underground wires with capacity for double or treble the present amount of dividend-paying work. The increased expenditure required for engines and dynamos was considerable, but the prospect of remunerative business for the outlay was exceedingly good. They had here, if they were to begin afresh just now with their provisional order, a central station building, and they had only to put in some more machinery, and to make arrangements for increasing the voltage of the supply to 200, to make it an exceedingly good property, not to be lightly parted with. The report was then adopted. The engineer (Mr. Munro) made a statement as to the position of the company, in course of which he said that the total number of lamps now connected to the station was 13,000, as compared with 9,000 last year. It was impossible to absolutely forecast variations of demand, but if the sales increased in proportion to lamps connected, the revenue next year ought to be at least a third more than that of the present year.

JUNGFRAUBAHN GESELLSCHAFT.—This company has been formed in Bern, with a capital of 4,000,000fr. (£160,000), and takes over the Jungfrau electric railway from the concessionaire, Herr Guyer-Zeller. The new company has also borrowing powers to the extent of 4,000,000fr.

MEXICO ELECTRIC TRAMWAYS (LIMITED).—Coupons (No. 1) of the Five per Cent. Debentures are payable at the offices on and after Jan. 2.

NEW ITALIAN ELECTRICAL COMPANY.—The business of the Tecnomasi Italiano, Ing. B. Cabella and Co., has been converted into a limited liability company, with a capital of about £80,000.

SIEMENS AND HALSKE ACTIEN-GESELLSCHAFT.—The Directors of this company have declared a dividend of 10 per cent. for the year ended July 31, 1898.

NOTES.

OUR issue this week, being the first in the year, contains the usual mass of statistical and other information relating to electric supply undertakings. We may first refer to the annual large sheet supplement Table of Electricity Supply Works of the United Kingdom, which is now made more complete than ever. Indeed, so numerous have these undertakings become, and so copious is the information which, with the kind assistance of the engineers and other officials, we have been able to collate, that to avoid unwieldy dimensions we have decided to print on both sides of the sheet. Those requiring copies of the Table, mounted on linen, will, as usual, be able to obtain these early in February. We take this opportunity to thank those who have contributed to make this Table a success, and we hope they will be adequately rewarded by the completeness and usefulness of the information now available.

APART from the length of this table, perhaps the most noticeable feature this year is the large increase in the number of electric supply undertakings which return a "declared pressure" of 200 volts, or over. These now number 87, of which about half do not give an alternative supply at 100 or 110 volts. We are glad to note also a considerable improvement in the motor connections; last year only five stations returned their motor load at over 100 H.P., while this year 18 have more than 100 H.P. in motors connected to their mains. There is still, however, considerable room for improvement in this respect.

AMONGST other matters relating to electric supply undertakings there will be found a list of the electric lighting notices under the Board of Trade, which confirms the evidence of our supplement Table as to the continued rapid expansion of this class of works. The financial aspects of electricity supply are well brought out in an article comprising a number of instructive diagrams and statistical tables. In this article the mass of figures embodied in our weekly analyses of electricity works accounts have been carefully and minutely systematised, with the result that the comparative performances and progress of a large number of representative works have been set out in a form that lends itself to handy reference.

WE may also direct the attention of our readers to a number of descriptive articles which we publish this week. The technical accounts of the recently-opened electric supply works at Salisbury and Eccles are especially appropriate to the special character of this particular issue. As representing some of the more interesting features of Continental practice, and thus affording an instructive comparison with home methods, Prof. SEMENZA's description of the Paderno installation will, we are sure, be welcomed by our readers.

THE Revenue Returns just issued for the third quarter of the financial year show a very satisfactory improvement, including a handsome increase in telegraph receipts amounting, for the whole period, to £40,000. There are indications that the trade of the country is at present in the growing phase; and of this no surer sign can be found than the steady rise in telegraph revenue which is the infallible barometrical indicator of national well-being. We may confidently anticipate, therefore, that the POSTMASTER-GENERAL will be able to report on April 1 next the unusual occurrence of a surplus in the Telegraph Account; and should this be the case he will have no difficulty in obtaining the funds which, according to the *Standard* of Monday last, he is at present in need of to carry out further extensions, whether for telegraphic or for telephonic purposes.

WE do not stand alone in complaining of the narrow scope of the latest batch of New Year's honours, nor in noticing the scanty recognition doled out to science and intellectual attainments. Political and military claims must naturally and rightly take precedence of the claims of art, literature and science; but there remains some ground for surprise that

Digitized by Google

such meagre acknowledgment of these peaceful fruits of civilisation has been exhibited in the latest list of recipients of these honours. The reason is certainly not to be found in any lack of eligible candidates; for even in the comparatively restricted circle directly associated with electrical science and its applications, we could name not a few whose services for the nation have not been duly recognised thereby. To cite only one instance, when will this country follow the example of other nations in doing honour to the excellent services of DAVID HUGHES? We have pleasure, however, in recording that among this year's honours are a C.B. for Mr. JASPER BADCOCK, of the Post Office, and a K.C.B. for Prof. W. C. ROBERTS-AUSTEN.

WE referred last week to the abandonment of the rental system of charging by the Smithfield Markets Electric Supply Co. Another "system" of charging has taken its departure at Norwich, where until recently there had been in operation a curious method of registering current by means of meters which worked at only half-rate before sunset and after 8 p.m. This system was ingeniously contrived, and it attracted considerable notice from electrical engineers; but we do not know of any instance where it has been imitated. The Norwich Electricity Co. have decided to adopt a uniform tariff of 5d. per unit in future, in place of the former scale of 7d. after sunset and before 8 p.m. and 8½d. at other times of the day.

PARTAKING in the extensive opposition to the General Power Distributing Company's Bill for the wholesale supply of electricity in the Midlands and South Yorkshire, the TOWN CLERK of Nottingham has sent a letter to the newspapers, in which he states that "Parliament is now asked to go back upon the legislation of the last quarter of a century, and to introduce into our localities those elements which have been destructive of the wise and peaceful administration of our commercial affairs in the past." He further adds that "the establishment in our midst of a company with the powers asked for by the Bill would land us in all the difficulties, perplexities and friction of the times when the gas and water were controlled by private companies."

THIS reference to the gas and water companies may be adroit, but it is not convincing; moreover, it is really quite beside the mark. It is not proposed that the General Power Distributing Company, nor any of the similar concerns, should have a monopoly like that of the gas or water companies; but that they should be permitted to supply cheap power, in healthy commercial competition with the local authorities who are professing such alarm. If the companies cannot supply as cheaply as the authorities themselves can do, these latter need not be alarmed; but if the companies can supply more cheaply, surely it is the prime duty of the local authorities to see that the ratepayers and others in their districts speedily obtain the benefits of the cheaper supply. Are great industrial interests to be placed in jeopardy because, forsooth, municipal bodies shrink from the "difficulties, perplexities and friction" a new combination of circumstances would impose upon them?

NOR is it fair on the part of the TOWN CLERK of Nottingham to represent the proposed legislation as "going back upon the legislation of the past quarter of a century." On the contrary, it is the most natural and logical step forward, as dictated by the engineering and social developments of electric supply during the last decade. It is equally preposterous to stigmatise these schemes for wholesale supply by companies as "elements which have been destructive of the wise and peaceful administration of our commercial affairs in the past." We are surprised at the confession that wise and peaceful administration has been destroyed; but it passes comprehension what particular piece of legislation on behalf of anything analogous to the schemes under discussion can have done this thing. Surely the one and only new element introduced lately into the relation of local authorities with electrical enterprise is the practice of municipalisation. It would not surprise us if *that* proved, indeed, an element "destructive of wise and peaceful administration."

THE doctrine is a mischievous one that, because local authorities have acquired works for any specific purpose, such as electrical supply, the protection of those works and of the capital invested in them demands the suppression of all private enterprise and independent progress in the same direction. It is a doctrine the effects of which must in the long run recoil most disastrously upon the very communities whose governing bodies adopt it. In our opinion, the fact of such a doctrine being advanced, in defence of the arbitrary protection of municipal capital, points clearly to the mistake in risking that capital in works of a commercial and progressive character—is, in fact, the *reductio ad absurdum* of municipal trading.

A NUMBER of important electrical patents will expire this year unless applications for prolongation are made and granted. Among those of particular interest, in the list which appears in another column, we may give the first place to No. 3,379 of 1885, which is the famous Zipernowsky-Déri transformer patent, now the property of Mr. MARTIN RUCKER, in connection with which extensive litigation was threatened last year. Since the meeting of the Municipal Electrical Association, at which it was decided by the interested owners of central stations to combine in resisting Mr. RUCKER's claims, we have heard no more of the matter. Probably this gentleman has been advised that to devote capital to fight the matter out would be an even more risky speculation than an investment in cycle shares. It is interesting to note that the patent in question was amended as recently as April 3, 1897. In addition to this patent claiming an alternate current transformer system with transformers in parallel, there is another patent by the same two inventors in conjunction with O. T. BLÁTHY, which has been kept alive since 1885 by payment of the necessary fees. This second patent refers to the construction of transformers.

ANOTHER alternating patent which will have run its allotted span this year is that of S. Z. DE FERRANTI, dated Dec. 11, 1885. It describes some useful and some necessary adjuncts to the alternating-current transformer system. The first of

Digitized by Google

these is the use of electromagnetic switches to automatically switch parallel transformers in or out according to the current required from them, the second is the high pressure main known now as the "Deptford" type. A claim is made for the combination of fuses or automatic cut-outs in the branches of the high-pressure circuit to which the transformers are connected, and finally the system of leakage indication by means of electrometers connected between each main and earth is described. Mr. FERRANTI has one more 1885 patent with a broad claim, namely, for a switch "so arranged that the continuous movement of the handle stores up energy in the spring bridge-piece and afterwards liberates it . . ."

ALTHOUGH the early alternating-current patents claim a large share of attention, there are other electrical patents dating from the same year of equal importance commercially. Mr. DESMOND FITZGERALD'S "lithanode" was patented in 1885, also the COWLES electric furnace. Three important patents of Mr. DELANY'S for multiplex telegraphy will expire in 1899 in the usual course of events, a motor-suspension patent of Mr. FRANK J. SPRAGUE'S, and, finally, a patent granted to JAMES BROCKIE and BENNETT PELL for improvements in arc lamps.

THE Publisher desires to call attention to the closing up of the Handbook and Directorial Divisions of the "Electrical Trades Directory and Handbook for 1899." Owing to the work of compilation proving exceptionally heavy this year, he will be glad to receive entries intended for insertion in the new edition as promptly as possible. The issue for 1899 will contain much new matter of interest and importance to the electrical and engineering industries, in addition to the old well-known features brought quite up to date.

Cable Interruptions.—	Date of Interruption.
Para—Maranham	Nov. 15. 1898

Erratum.—On page 338, column 2, line 27, in our issue last week, *for* "increased" *read* "decreased."

King's College (London).—The Lent term commences on Thursday, January 19th. Particulars of the courses of instruction are given in an advertisement elsewhere.

Electric Lighting in the Vatican.—On Sunday last the palace of the Vatican was for the first time lighted throughout by electricity. The cathedral of St. Peter is also shortly to be equipped with electric light.

Appointment.—Mr. John Aldworth, manager of the Isle of Man electric and other tramways, has been appointed to succeed Mr. Baker as manager of the Nottingham Corporation tramways. By this arrangement Mr. Baker will be enabled to take up his duties with the London County Council at the end of this month.

Gibraltar - Malta - Alexandria Cable.—The third cable of the Eastern Telegraph Co., between Gibraltar, Malta and Alexandria is now being laid by the Telegraph Construction and Maintenance Co.'s c.s. "Anglia," the shore end having been laid at Gibraltar on Tuesday. It will be remembered that the section connecting Porthcurno with Gibraltar was laid in the autumn of 1898.

Trolley Ropes.—A correspondent, signing himself "Pro Bono Publico," has written to us suggesting that the example set at Bristol should be followed on all trolley lines, viz., that the trolley rope should be attached to the trolley standard after the trolley arm has been reversed, the ropes being unhooked from the standards only when it is required to reverse the position of the arm.

Electrically-Driven Type-setting Installation.—The type-setting department of the *Newcastle Daily Journal* has just been equipped with an installation of Langdon-Davies alternate current motors, by Messrs. Ernest Scott and Mountain. This is stated to be the first installation of the kind in the northern counties. The motors are used for operating a set of the latest pattern of "Linotype" type-setting machines.

Supply Interruption at Ayr.—A report has only just come to hand of an interruption to the electrical supply at Ayr on the 29th ult. A short-circuit occurred on one of the circuits, and the consequent blowing of its fuse interrupted the supply to a considerable portion of the town. The local report is to the effect that the failure was due to a fuse blowing in a sub-station, causing a short-circuit and blowing the main works fuse. This, it is to be hoped, is not quite accurate.

The Wright System in America.—The Edison Electric Illuminating Co., of Boston, announces that, after having experimented for some months with the Wright maximum demand indicator, it is prepared to supply electric current on this tariff system. The price charged has hitherto been 1c. per hour for a 16 c.p. lamp, with discounts of 10 to 15 per cent., and it will now be 1c. per lamp per hour for the first annual 400 hours of maximum demand, and after that 0·4c. per hour.

"Electric Fluid" in Liverpool.—Judging by a paragraph in the *Liverpool Express*, headed "The Dangers of Electric Lighting: Startling Incident," it would appear that a most virulent form of "electric fluid" is in use in that city. In the evening of January 1, "a portion of the apparatus connected with the main in Tithebarn-street burst out into a flame, and the explosion created some alarm in the neighbourhood. The electric fluid ran along the pavement to a considerable distance, and a large stone flag was shattered." The occurrence appears to have been a slight gas explosion in an electric lighting conduit, of the usual character. Nobody was injured and the supply was not interrupted.

The National Telephone Co.'s Reconstruction Bill.—We referred in our issue of Dec. 2nd to three bills which are to be introduced in Parliament this session by the National Telephone Co. Of these, two relate to the acquisition of additional powers by the company, and the third seeks sanction for a scheme of reconstruction. Further particulars of the latter are now to hand. The share capital of the new company is to be £6,000,000 with power to raise a further £3,000,000 by the creation of debenture stock. Of this capital £4,000,000 is represented by the share capital of the existing company, and £1,669,471 has already been raised by debenture stock out of an issue of £2,000,000. The preamble of the Bill states that telephone messages at the rate of 450,000,000 are now passing annually over the company's system. A conversation is estimated as two messages.

Obituary.—We regret to announce the death of Dr. Eugene F. A. Obach, which took place on the 27th ult. at the house of his brother, at Graz, in Styria. Dr. Obach was born in 1852, at Stuttgart, and was thus 46 years of age at the time of his death. He studied at the polytechnic of his native town, and subsequently lectured on chemistry at the Veterinary School. Thence he went to Leipzig University, where he graduated as a Ph.D. in 1875. He entered the employ of Messrs. Siemens and Halske, as assistant to Dr. Werner Siemens, in the spring of the same year. In 1876 he came to England and joined the staff of Messrs. Siemens Bros. and Co. at Woolwich, as chief of the experimental department. He was the writer of several useful monographs and papers on electrical subjects. He also displayed considerable inventive ability, and his tangent galvanometer and dry cell are well known.——We regret to announce the death of Mr. Henry H. Beit, A.I.E.E., a partner with Mr. T. Scott Anderson in the firm of Scott Anderson and Beit, Sheffield. Mr. Beit was in partnership with Mr. Scott Anderson just a year, having previously served as a pupil and then as engineer. For some

Digitized by Google

time past Mr. Beit had been ill, but a fatal termination was not anticipated. He was educated at Rugby, and was only 26 years of age.

Municipal v. Company Working of Electrical Undertakings.—"The beginning of the New Year," says the *Journal of Gas Lighting*, "brings into prominence the seething antagonism between municipalities and electricity supply companies, which began to be acute last year. It is a pleasing trait of our modern 'progressive' municipalism to hold that what is sauce for the municipal goose in the shape of competition in electricity supply, is by no means sauce for the gander of private enterprise. It is perfectly right and proper for the Vestry of Marylebone or of Bermondsey to enter into competition in this business with a company, but by no means the same for a General Power Distributing Co. to offer a cheaper supply of electricity to consumers in the area supplied by a local authority. Thus baldly stated, the municipal attitude appears illogical in the extreme; and it is no wonder that the leading electrical journals are poking fun at it. What Parliament thinks of the question will be shown before the session is out; but the action of the House of Lords in passing the General Power Distributing Co.'s Bill is rightly regarded in municipal circles as boding ill for the maintenance of their 'monopolies.' Of course, in such emergencies there is always somebody who undertakes to 'agitate' the matter on behalf of the threatened interest. Hitherto the sacred cause of Progressive Municipalism against private electrical enterprise has been worked for all it is worth by the journal called *London*, as we have had previous occasion to notice. The style of this periodical, however, is somewhat crude, not to say loud; and in its pronounced taste for highly-flavoured personalities, it has suggested the cheap evening newspaper rather too pointedly to win the respect of the grave and severely respectable personages who serve the public of this country by means of its municipal institutions."

Storage Battery Competition.—As a sequel to the motor-car trials mentioned in *The Electrician*, Vol. XLI., p. 578, the Automobile Club de France announces a competition for motor-car accumulators, to take place in Paris in April, 1899. Tests will be made on the life of the cells, and on their useful efficiency, and account will be taken of the "frequency, importance and facility of operations for maintenance," and of the weight of the cells per capacity and per output. Entries can be made up to Jan. 31, at a fee of 500fr., and up to Feb. 28 on payment of a double fee; in addition to this owners of batteries will have to pay 1fr. per kilowatt-hour metered to their cells. Each battery submitted must be capable of furnishing 120 ampere hours when discharged at 24 amperes, without its terminal pressure dropping below 8·5 volts, and must not weigh more than 110 kilogrammes. The reason of fixing the pressure and not the number of cells is to enable batteries other than lead-lead to compete. Discharge tests will be made for five hours every day, the current being varied according to a specified curve between 20 and 100 amperes every 20 minutes (the 100 ampere discharge will only last half a minute in each cycle), this being followed by 10 minutes' repose. While these discharges are taking place, the cells will be jolted about in imitation of the treatment they are liable to on ordinary roads. The daily charge will be given for a maximum of eight hours, but any competitor may stop the charge to his battery when he likes. The charging current will start at 30 amperes and gradually diminish to 15 amperes. Between the charge and discharge (an interval never exceeding two hours) owners of the batteries may clean them and renew the strength of the electrolyte, but no plates may be changed. Once a week a test discharge, without jolting, of a steady 24 amperes for five hours will be made. During this time, if the voltage of any battery drops below 8·5, it will be removed from the circuit, and after four cases of such misbehaviour it will be considered as worn out so far as the tests are concerned, and the tests mentioned will be systematically continued until all the batteries are worn out—but not longer than six months.

Electricity in the Spanish-American War.—At a meeting of the New York Electrical Society held on the evening of December 14th, Eugene Griffin, Colonel of the First Regiment of Volunteer Engineers and first Vice-president of the General Electric Co., gave an address entitled "Ideas Underlying the Organisation of a Volunteer Engineer Corps: the Work Accomplished by it in Porto Rico and the Opportunities for Further Usefulness." Col. Griffin, our New York correspondent writes, spoke of the reluctance of the War Department towards the question of organising a corps of 2,500 men. The work of the volunteers was compared with that of the regulars, the conditions of ordinary military service being in this case, he said, slightly reversed, the volunteers being professionals and the regulars, to a certain extent, amateurs in engineering work. There was very little electrical work done in Porto Rico by the First Regiment of Volunteer Engineers under the speaker's charge, although more electrical work might be expected in any future war. He suggested the organisation of a permanent torpedo militia of electrical engineers and the immediate preparation of thorough reports on the experience already gained in order that the knowledge thus obtained might be available for future emergencies. Mr. F. W. Roller, who was chief engineer of the United States gunboat "Nashville," addressed the meeting, giving some valuable data on the experience obtained with electrical apparatus on shipboard. He stated that electric apparatus of the signalling variety, that is, where small powers are used, was, as a rule, a failure at the time when it was most wanted, namely, during an engagement. The heavy concussions, the severe service and the lack of opportunity for keeping it in repair are the causes for this. Engine-room telegraphs and other signalling devices, as at present designed, are much too delicate. The electric range-finder also proved itself a complete failure, owing not so much to the delicacy of the apparatus as to inherent defect in attempting to find the height of a very long triangle with a very short base. Electrical apparatus of the type using large powers, namely, dynamos, motors, incandescent lamps and the searchlight, proved to be a great success during the war, the searchlight being one of the most useful pieces of apparatus in the navy. It was the searchlight that, shining up the narrow entrance of Santiago harbour, prevented Cervera from coming out by night. The Ardois signalling system was, as might be expected, much more satisfactory than oil lamps bent to a halyard and run up in the rigging for every signal. Electric firing mechanism proved itself superior to percussion. Mr. Roller gave some figures as to the excessive steam consumption on machines on which he had made tests. One duplex pump showed a steam consumption of 327lb. of water per horse-power-hour, another even running up to 343lb. One dynamo engine made the poor showing of 132lb. He advised that all new electrical apparatus, especially motor-driven steering gear and auxiliaries, be tested first in the merchant marine before any attempt was made to apply it to naval work.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

TUESDAY, January 10th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be read with a view to discussion: "High Speed Engines," by J. H. Dales.

RÖNTGEN SOCIETY.

8 p.m. General Meeting at 11, Chandos-street, Cavendish-square. Paper to be read: "The Present Position of the Röntgen Rays in Military Surgery," by J. Battersby.

THURSDAY, January 12th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting, when the Discussion on Dr. Lodge's and Mr. Evershed's Papers on Induction Telegraphy, will be concluded.

FRIDAY, January 13th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Students Meeting, when Dr. Archibald Barr will deliver an Address on "The Application of the Science of Mechanics to Engineering Practice."

CONTEMPORARY ELECTRICAL SCIENCE.

[Compiled by E. E. Fournier d'Albe.]

Dieletric Strength of Insulators.—Thomas Gray publishes the results of experiments made to test the dielectric strength of glass, hard and soft vulcanised rubber, mica, various cardboards and papers, oils and air. They were tested by means of a Westinghouse dynamo running at 8,000 revolutions per minute and connected with step-up transformers designed to raise the mean voltage as high as 100,000 volts should that be necessary. The specimens of "crystal glass" examined showed a dielectric strength of 285,000 volts per cm. in a thickness of 1mm., but with four layers making up a thickness of 4mm, the dielectric strength was only 200 kilovolts per cm. Hard rubber showed the same falling off in the dielectric strength when several layers were used. The various substances tested may be arranged in order of strength as follows: mica 2,000, hard rubber 500, soft rubber 450, "micanite," consisting of mica flakes held together by varnish, 400, paper 400 to 600, fuller board 200, Empire cloth 150, olive oil 70, air 50 kilovolts per cm. These are only rough average values. The papers are of special interest, as they provide cheap and effective insulating materials. American linen paper ranks high with 640, bond paper with 600, and tissue paper with 510. The oils were very troublesome, as their dielectric strength was found to vary with every considerable E.M.F. applied.

[Gray, *Phys. Review*, November, 1898.]

Photometer Records.—In the ordinary photometric process, there occurs between successive settings a considerable interval, in which the reading of the bar is taken and recorded, either by an observer or an assistant. Various expedients for reading the bar are resorted to, as, for example, the use of a hand-mirror to reflect a beam of light from one of the sources, or the turning on of a glow-lamp. These methods are not free from objections. The sudden influx of light produces in the observer fatigue of the retina and of the muscles of the pupil, and there is a consequent loss of visual sensitiveness. Further, when it is the question of the photometry of a fluctuating source, the infrequency and irregularity of the readings is a drawback. In arc-light photometry, more especially, the illumination of the photometer disc is a shifting quantity. C. P. Matthews obviates these difficulties by mounting a wooden cylinder parallel to the photometer bar, and puncturing it by means of a steel pin attached to the handle of the photometer carriage. A ratchet-wheel turns the cylinder by a definite amount as each record is made, so that the records can be identified afterwards. The measurements are then made, either by bringing the pin into coincidence with each puncture and reading the bar, or the cylinder is covered with paper ruled in a divided scale and the readings are taken from the paper direct. When time-variations are to be studied the cylinder is worked on the chronograph principle.

[Matthews, *Phys. Review.*, November, 1898.]

Photographic Studies of the Arc.—Some capital photographs illustrating the course of events in the alternate-current arc have been obtained by N. H. Brown. They were taken either by moving the plate across the back of the camera and letting the image draw itself out, or by placing a slit in front of the moving plate, so as to get the complete history of a definite part of the arc. The photographs show that the lighting up does not take place across the whole arc space at the same instant, but that it starts first from one side and then from the other. The slit photographs show that there are really two light-fronts, one from each carbon. The positive light-front starts about $\frac{1}{1000}$th of a second before the negative one, and travels across at the rate of about 500in. per second, while the negative light front moves at the rate of about 300in. per second. This is generally in accordance with the known fact that the steepest potential gradient is close to the positive carbon, and suggests a movement of ions as in electrolysis. But it is not at all certain that a complete explanation can be attained along these lines. For the differences of temperature between the carbon and the intervening gas, and between the two carbons themselves, must have some determining effect upon the flame. The light-front is not necessarily composed of projected particles. It may be a heat wave in which radiation plays an important part.

[Brown, *Phys. Review*, November, 1898.]

Charge of Röntgen Ray Ions.—When Röntgen rays traverse a gas, the molecules of the gas are ionised, and the gas becomes a conducting medium for an electric current. By measuring the current passing through a gas exposed to Röntgen rays and acted upon by a known E.M.F., we may determine the value of the product nev, where n is the number of ions in unit volume of gas, e the charge on an ion, and v the mean velocity of the positive and negative ions under the E.M.F. to which they are exposed. J. J. Thomson describes some fascinating experiments undertaken with a view to determine e. His method is founded upon Wilson's discovery that when Röntgen rays pass through dust-free air a cloud is produced by an expansion which is incapable of producing condensation under ordinary circumstances. The ions act, in fact, as nuclei for the deposition of the moisture. The cloud is produced between an aluminium plate exposed to X-rays and covered with moist blotting paper, and a water surface. The rate at which the cloud settles down gives v, and also indicates the size of the drops, which may be calculated from the known laws of bodies falling through a gas. Knowing the size of the drops, and the mass of water deposited, the number of drops per unit volume is known. This number is n, the number of ions, provided all the ions are caught. The author shows how this can be insured. Thus, only e remains to be found. It is calculated from n, v, and the total quantity of electricity passed in a given time. This is the method in bold outlines. For details and corrections the original Paper should be referred to. The mean of the results for air is $e = 7{\cdot}8 \times 10^{-10}$ electrostatic units. Allowing for that part of the cloud which is formed independently of the rays, the value for hydrogen is the same as for air. It is important to notice that the above value for the charge on the ion produced by X-rays is of the same order as that carried by the hydrogen ion in electrolysis, and by the ions whose motion causes the spectrum lines which exhibit the Zeemann effect.

[Thomson, *Phil. Mag.*, December, 1898.]

True Resistance of Cells.—The chief difficulty in the way of finding a definite value for the resistance of an electrolytic cell lies in the polarisation. There are other complications, due to the absorption of ions in the metal of the electrodes, and to convection currents, but these can, by proper arrangement of the apparatus, be reduced to vanishing point. Polarisation sets in so instantaneously that even Kohlrausch's method of measuring resistances by means of a telephone and rapidly alternating currents suffers under the errors due to it. K. E. Guthe, therefore, proposes to employ direct currents, and to eliminate polarisation by determining its exact amount. This is done with the aid of Wiedeburg's theory of polarisation, which is so far the closest in accordance with facts. The author shows that the apparent resistance is always too large. Denoting the apparent resistance by ρ, the true resistance by r, the polarisation by P, and the current by I, we have

$$\rho - r = \frac{P}{I}(1 - e^{-kI}),$$

which shows that the difference is enormous for very small currents, and disappears with very strong currents. This explains the constancy of Haagn's results, as he operated with large currents. The author uses a pendulum apparatus for obtaining a constant time interval for the current, and after allowing for polarisation as above, the true resistance r is found to be constant within the limits of observational error.

[Guthe *Phys. Review*, November, 1898.]

SALISBURY ELECTRIC SUPPLY WORKS.

A combined water-power and steam-power electricity works was inaugurated on December 19th, at Salisbury, by a local electric light company, the ceremony, as announced in our columns, being performed by the Earl of Pembroke. Notwithstanding the comparatively small size of this undertaking, it possesses many features of exceptional interest, these being somewhat out of the usual beaten track of electricity works construction. A technical description of these new works will, therefore, probably be of interest to our readers.

Not many years ago the electrical profession was exhorted by Mr. Preece and other leading engineers to make use of the water power running to waste in the rivers, streams and rills of this country. Mr. Preece backed up his exhortation by a practical example that has afforded many instructive and interesting lessons, viz., the municipal water-power station at Worcester. Some of the more enthusiastic, but less practical, advocates of water power predicted an appreciable decline in the use of steam and gas power, but these individuals overlooked the fact that, save in a few exceptional localities, the streams in this country do not afford satisfactory and remunerative conditions for running a town lighting station. Neither have we the immense volumes of water flowing over a moderate fall, as at Lachine Rapids, on the St. Lawrence River, nor the smaller volumes flowing from immense altitudes as in the waterfalls of Switzerland and the Rocky Mountains. England, therefore, is by natural circumstances precluded from becoming a country of great water-power undertakings. Tidal power, by the way, is often advocated by the layman; but even the novitiate engineer can soon figure out that, to mix the metaphor, "the game is not worth the candle." We expect nothing important from tidal power. There have not been wanting in the past, however, successful attempts to utilise the water power of rivers in electric light undertakings, of which Worcester, Buckingham, and most recently Salisbury, afford instructive examples.

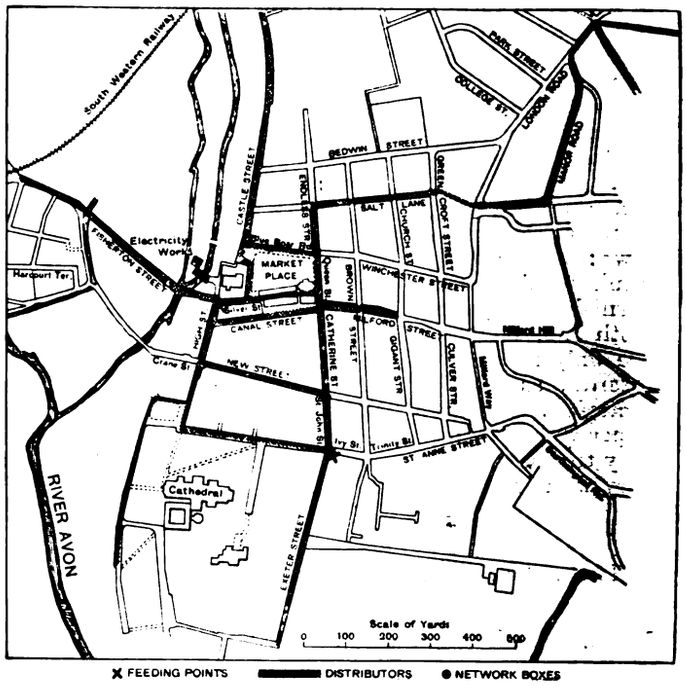

FIG. 3.—Map showing the System of Mains, Feeding Points and Network Boxes, &c., of the Salisbury Electric Supply Works.

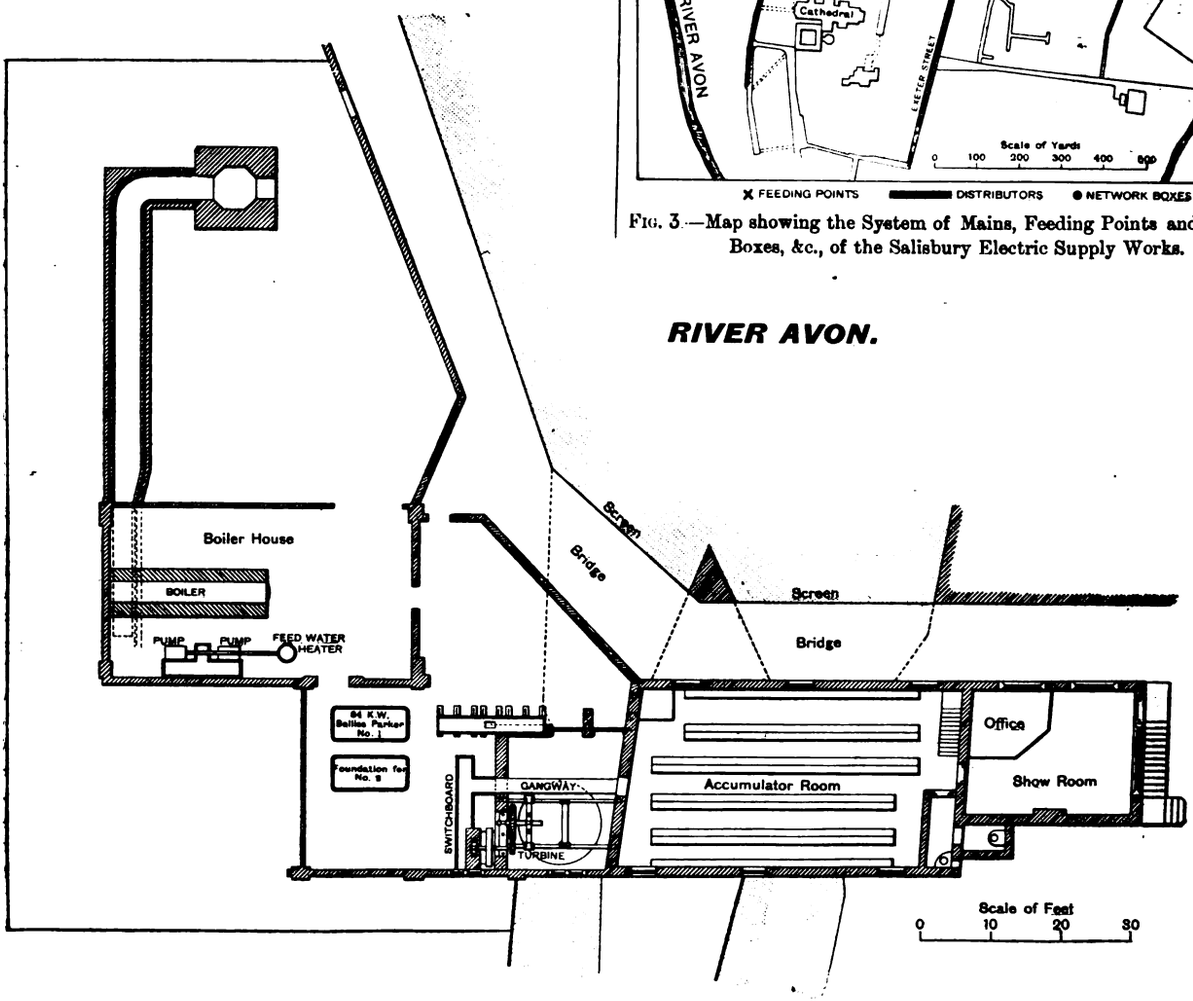

FIG. 1.—Salisbury Electric Supply Works. Plan of Station.

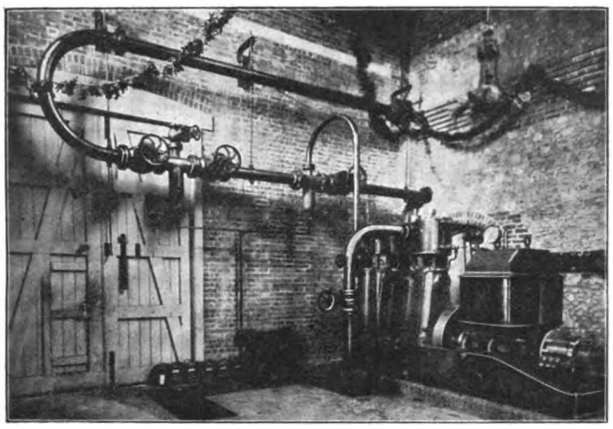
In 1894 a few enterprising gentlemen started an electric light company in Salisbury. They secured an option to purchase the old Town Hills and adjoining land as a site for the works, and in due course obtained a Provisional Order. As is usual in a country town, it was found very difficult to raise the necessary capital, and, as the Board of Trade threatened to rescind the Order, the Company approached Messrs. Edmundson's Electricity Corporation (Limited), of West-

Digitized by Google

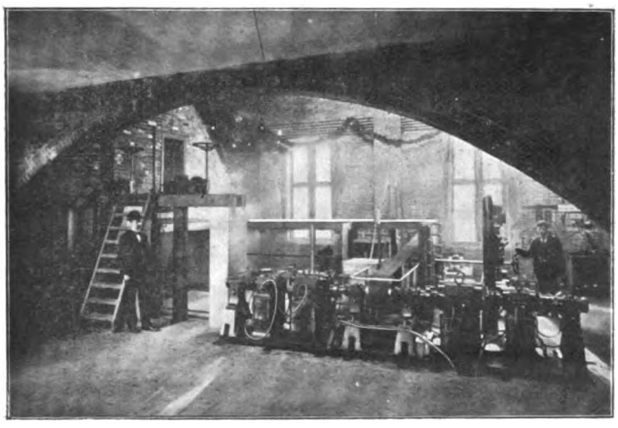
minster, who undertook to find a portion of the capital required if the remainder was procured locally. Only a small further sum was subscribed locally, but Messrs. Edmundson, having in the meanwhile largely increased their capital for the express purpose of dealing with such contracts, eventually undertook to put down the works, finding nearly all the capital required. The works in Salisbury have throughout been designed by Messrs. Edmundson and carried out by them, and they have every reason to be proud of the result. Mr. L. A. Hards, who acted as their resident engineer, is now engineer to the Salisbury Company. A better position for a supply works than the old Town Mills it would hardly be possible to secure, it being not more than 100 yards from the centre of the city; the site is about half-an-acre in extent, and was the



Salisbury Electric Supply Works. View of the Steam-driven Generating Plant.

property of the Dean and Chapter of the Cathedral for seven centuries. The old Town Mills is on the site where a mill probably already stood when the city was moved in the thirteenth century from its first position on the top of a neighbouring hill to its present situation at the junction of the Avon and the Nadder, the former of which now supplies part of the energy for supplying light to the city.

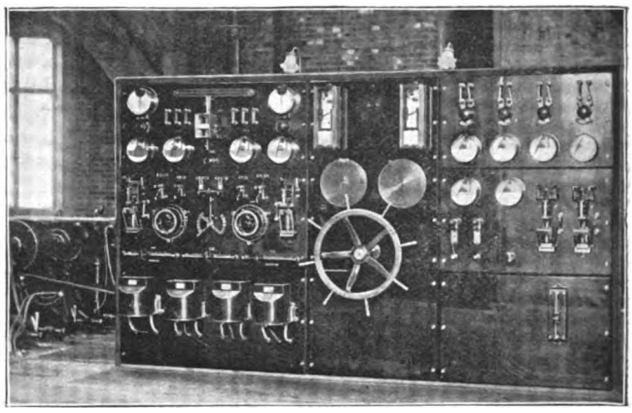
The present mill buildings are only about 150 years old, and were fitted with four undershop wheels, which were used for flour and snuff grinding. One of these had previously



Salisbury Electric Supply Works. Interior of Power Station, showing Water-driven Machinery.

been removed, and an iron eel trap grating fitted in place. Fig. 1 shows the plan of the works. The east end is a new two-storied building, used as an office and show room, with a store and workshop below. The next building is the old four-story mill, having on the ground floor the eel trap, tank and storm water gate at one end, also further storage room at the other end. On the first and second floors are the accumulators and the upper floors are empty. The engine room is a new building containing the turbine, engines and dynamo. The boiler house is at right angles, and the triangular-shaped room between is intended to hold the condensers when the load on the steam plant warrants the cost of adding these. The whole of the engine and boiler house are built of fire-proof materials, the roof being iron, glass and tiles, the walls are built for the most part of flints set in cement. A siding of the South Western Railway adjoins the Company's property; and some day, no doubt, this will be used, but for the present, as the coal consumption will be small, fuel will be carted to the works. The chimney is octagonal, 100ft. high and 6ft. diameter inside.

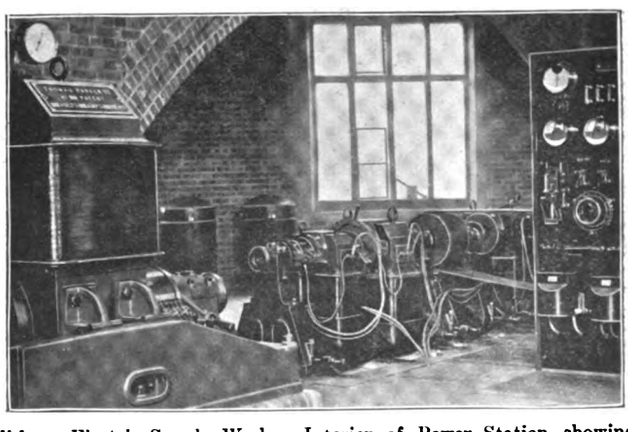
There are at present in place a 60 H.P. vortex turbine dynamo, one Babcock and Wilcox boiler of 1,218-heating surface, two Worthington feed pumps, one of Joseph Wright's excelsior feed heaters, and a Bellis-Parker set of 84 kilowatt output, 160 ampere and 460 volts. Space has been left and all pro-



Salisbury Electric Supply Works. View of the Switchboard.

vision made for adding another boiler and engine set when required, but it is probable that so much useful work can be obtained from the turbine, that these will not be required for another year. The steam pipes are on the usual ring main principle, and the feed pipes, &c., are in duplicate. A galvanised iron tank capable of holding 2,000 gallons is supported by an arch high up in the boiler house to supply the feed heater.

The station is at present being run from the turbine, which was made by Messrs. Gilkes, of Kendal, the wheel is 8ft. 6in.



Salisbury Electric Supply Works. Interior of Power Station, showing arrangement of the Plant and Switchboard.

in diameter, and is capable of giving 60 H.P. with 5,883 cubic feet per minute working under a 7ft. head. It runs at 26 revolutions per minute and drives the dynamo at 850 revolutions by gearing and belting. The turbine is fitted with movable guide blades for adapting the entrance orifices to any quantity of water below the full supply. The hand wheel for adjusting is placed conveniently in the centre of the switchboard. As the vanes of the turbine are very massive an electric motor is to be fitted to give the switchboard attendant a quicker and easier control. The whole of the regulation is

Digitized by Google

carried out by this wheel, there being no use in inserting resistance in the field of the turbine-driven dynamo as the wheel only runs the faster to make up for the weaker field.

This turbine drives two machines coupled together, each capable of giving an output of 100 amperes at 230 volts, a machine being connected each side of the three-wire system. On the ends of the dynamos are coupled the boosters, to add ths extra pressure for charging the accumulators. The armatures of the boosters are wound on a sleeve and slipped on to the end of the spindles of the dynamos. In the event of the turbine being out of use, this machine can be used as an ordinary balancer booster combination by the removal of the belt.

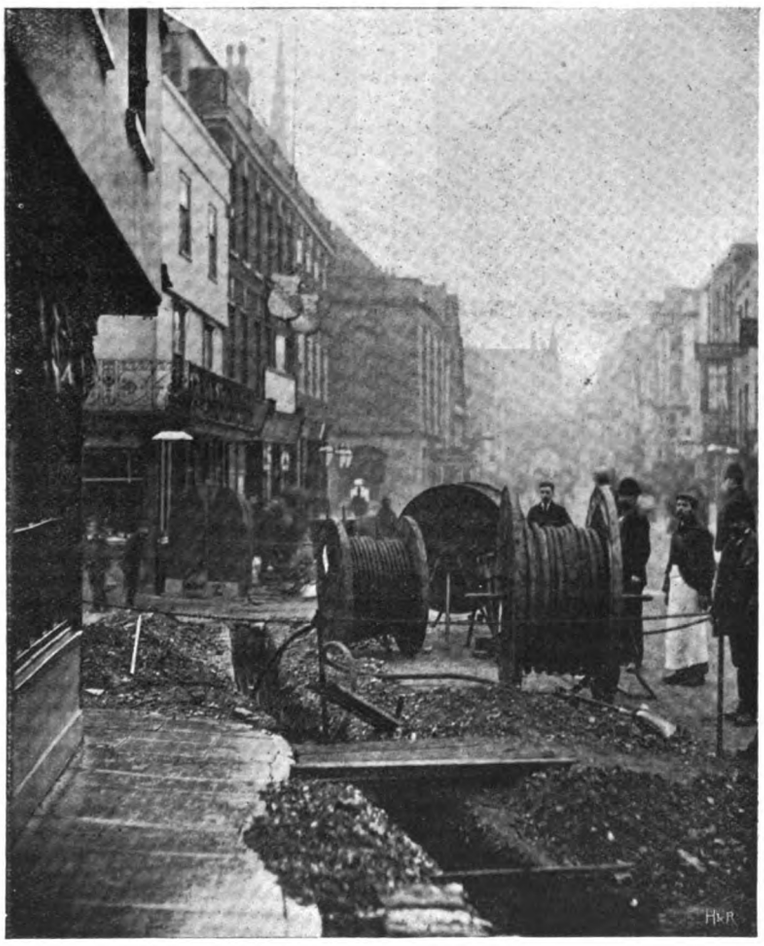
The switchboard, which was made by Messrs. Thos. Parker (Limited), to Messrs. Edmundson's designs, is very compact. It is divided into three parts. On the left-hand are the switches, ammeters, auto-cut-outs, &c., for the combination dynamo and booster, also the battety regulating switches and ammeters, the throw-over switches, zero indicators, &c. On the right-hand panel are the feeder, ammeters and duplex cut-outs, the dynamo-ammeters, auto-cut-outs, fuses, &c. The centre panel carries the recording voltmeters, recording ammeters on the earth connection to the neutral wire, cut-outs, switches, &c., for testing the insulation of the main. Through the centre of this panel projects the spindle of the gear for opening and closing the blades of the turbine, and an indicator is fixed, showing the position of the blades and also the level of the top and bottom water, so that at a glance the attendant can see the position of affairs. Two Kelvin large dial voltmeters—one on each side of the system—are fitted on the side wall, so that they can be seen when standing in front of the switchboard or any part of the engine room. The pressure at the consumers' lamps is 210 volts. Thomson-Houston meters are fitted on the output of the dynamos and on the battery circuits; these latter read forwards when charging and backwards when discharging, and, therefore, give the energy lost in the cells.

There are 230 accumulators of the D.P. type, having 715 ampere-hour capacity, or 80 amperes at 420 volts for nine hours, or 119 amperes for four hours.

At present the turbine runs for about 18 hours daily—in the morning for charging and in the evening with the cells to supply the light required. The water power varies very considerably, but even in the driest weather of last autumn there was always about 15 H.P. available, the average amount being from 25 to 30 H.P.; and when the river is flowing full there is 50 to 60 H.P. With the aid of a large battery this power can be fully utilised.

The mains are of Messrs. Callenders' jute-insulated lead-covered and armoured type, the feeders being concentric and the distributors three core. The lengths laid are:—

Feeder No. 1, 117 yards.
Feeder No. 2, 711 yards.
Sub-feeder, 567 yards.
Distributors 892 yards, 0·100 sq. in. section.
Distributors 584 yards, 0·075 sq. in. section.
Distributors 5,285 yards, 0·05 sq. in. section.



Laying Callender Cables for the Salisbury Electric Supply.

Already considerable extensions of the mains have been made owing to the demand for light in the residential districts of the city. In August last, the Corporation advertised for tenders for street lighting. They had previously been paying about £902 a year for gas, some of the lamps being extinguished at 11 p.m. during part of the year. The estimated extra cost of all-night lighting was £136, making the total £1,038. The electric light company quoted for 16 arc lamps (and 25 incandescents after 11:30) and 245 incandescents burning all night for £704, but the gas company reduced their price to £575 for all-night lamps and secured the contract for three years. Taking into account a number of additional lamps which are to be fixed, the advent of the

Digitized by Google

electric light company is said to have saved the city some £500 per annum.

Salisbury is a city of about 16,000 inhabitants, and to have secured the equivalent of 2,500 8 c.p. lamps, connected since the supply was started in July, is auspicious of a successful career. With a regular and ample supply of water-power the running expenses should be small, and we shall look forward with interest to the publication of the result of the first year's working.

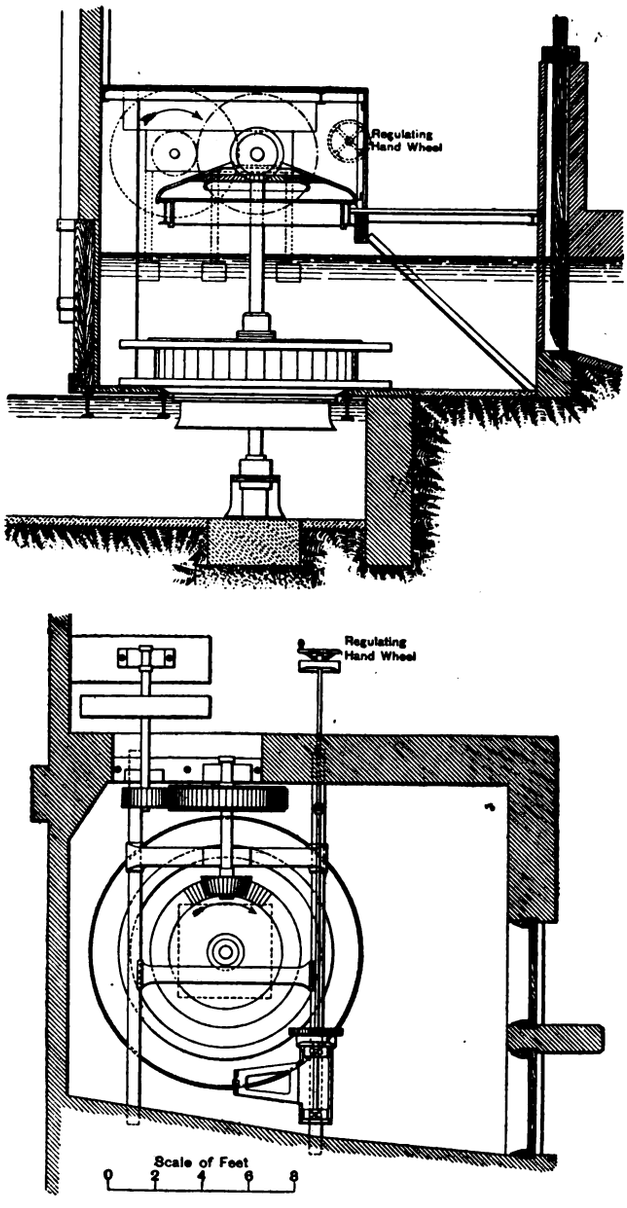


FIG. 2.—Elevation and Plan of the "Vortex" Turbine at Salisbury Electric Supply Works.

The following is a list of the principal contractors and sub-contractors, &c., who have supplied plant for this undertaking—

Dynamos and balancers...	Thomas Parker (Limited).
Engines	Belliss and Co.
Turbines	Gilbert Gilkes and Co.
Boilers	Babcock and Wilcox Co.
Feed Pumps	Worthington Pumping Co.
Switchboard	Thomas Parker (Limited).
Accumulators	"D. P." Battery Co.
Cables	Callender's Cable and Construction Co.

We are indebted to Messrs. Edmundson's Electricity Corporation (Limited) and to the principal contractors for the particulars embodied in this article, and to the first-named corporation for the photographs and drawings with which it is illustrated.

ECCLES ELECTRIC SUPPLY WORKS.

The history of the electric light question at Eccles dates from 1883. Eccles is a borough of some 35,000 inhabitants, distant about four miles from Manchester. The first occasion on which the subject of electric lighting was raised was when the Corporation of Salford intimated their intention of promoting a Parliamentary Bill containing clauses empowering them to supply electric light in the Borough of Eccles as well as in their own. This proposal met with protest on behalf of the Eccles authorities, and as a result the latter obtained a Provisional Order for themselves. As has been so often the case when a local authority has obtained a Provisional Order, nothing further was done for several years, except the renewing of the Order when necessary. On a renewal being granted in 1894, it was required that a certain area should be lighted within two years. The late Dr. John Hopkinson's advice was then taken, the usual series of visits were paid to central stations in operation, and the matter appears to have been shelved until the following year. Then Mr. S. V. Clirehugh was asked to prepare a scheme for lighting the whole of the borough. He recommended a high-pressure alternating-current system, proposing to utilise the existing gas lanterns, and placing incandescent lamps in them. The cost of the whole installation for supplying a private lamp connection of about 3,000, and lighting the streets with 700 lamps, was estimated at £20,000. By the casting vote of the Chairman of the Town Council, it was decided to apply to the Local Government Board for borrowing powers, but in view of the great opposition in the Council and among the ratepayers, the Local Government Board refused its sanction. Probably nothing more would have been done towards the electric lighting of Eccles had not private companies sought to obtain Provisional Orders, with the result that application was made to the Board of Trade by the Corporation for another extension of time. This was granted, but limited to one year. Mr. Clirehugh was then asked to modify his scheme to include the lighting of a more limited number of streets only, and finally borrowing powers were obtained, and the work which was estimated to cost about £11,800 was commenced in January last year. It has now been completed, and the small station was formally opened on December 14th by Alderman Kendall, Chairman of the Electricity Committee, in presence of the Mayor and Mayoress, the latter performing the operation of switching on the current.

The works are situated by the Bridgewater Canal, a few hundred yards above the Barton Aqueduct, where it crosses the Manchester Ship Canal. The Bridgewater Canal is separated from the works by a roadway only, and supplies water for condensing, although the town supply is laid on, to be used in case of emergency. Messrs. George Macfarlane and Co., of Manchester, erected the buildings to the plans of Messrs. Woodhouse and Willoughby, of the same city. The frontage occupies 75ft., of which 25ft. represents the width of the engine room, and the remainder is the length of the boiler house. The ground acquired by the Corporation is 198ft. long, so that ample allowance has been made for future extensions. The buildings comprise the engine room, 44ft. by 25ft., the boiler room, 42ft. by 45ft., the accumulator room, 10ft. by 20ft., and offices, &c.

The whole of the steam generating plant has been supplied by Messrs. Tinkers (Limited). Only two boilers have been erected at present, these being of the Lancashire type and embodying the most modern improvements. Provision has, however, been made for extensions. The boilers are 28ft. long by 7ft. 6in. internal diameter, each having two flues 3ft. in diameter. The longitudinal seams of the shell are butt-jointed, with covering strips inside and out, secured with four rows of rivets; the circular seams are lap-jointed and single-riveted. Each ring of the shell is formed of one plate $\frac{5}{8}$in. thick. The flues are formed of solid-welded and machined-flanged rings made of plates $\frac{15}{32}$in. thick, the front and back rings being $\frac{9}{16}$in. thick. The end-plates are $\frac{5}{8}$in. thick, each formed of one plate. Both ends are single-riveted to the shell, the front end being attached by an external angle ring, and the back end being flanged. The boilers rest on special

Digitized by Google

seating blocks, manufactured by Messrs. Poulton and Co., and these are placed at all points of contact with the boiler shell. The working pressure of the boilers is 125lb. per square inch, and the test pressure 210lb. per square inch. The main steam pipe is 8in. bore, and provided with water catchers at each end. Valves are fitted in the main steam pipes, so that any section can be shut off without interfering with the working of the other.

The water for condensing purposes is pumped from the canal by a centrifugal pump, driven by a separate vertical engine, through two Ledward ejector condensers, each capable of dealing with 6,000lb. of steam per hour. The condensed water returns to a tank capable of holding 300 gallons, from which it is taken by means of a horizontal duplex feed pump, made by Messrs. Mumford, and capable of delivering 7,000lb. of water per hour against the working boiler pressure. This

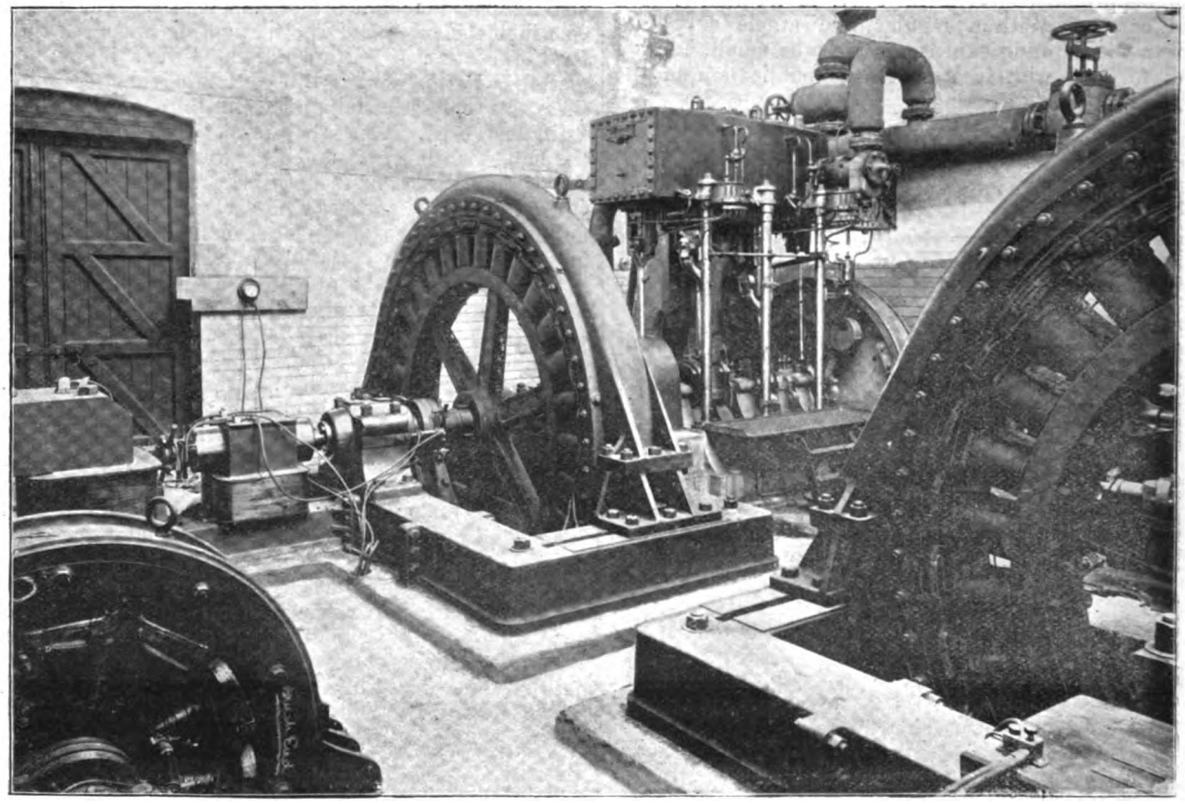

FIG. 1.—View of Engine Room at Eccles Electric Supply Station.

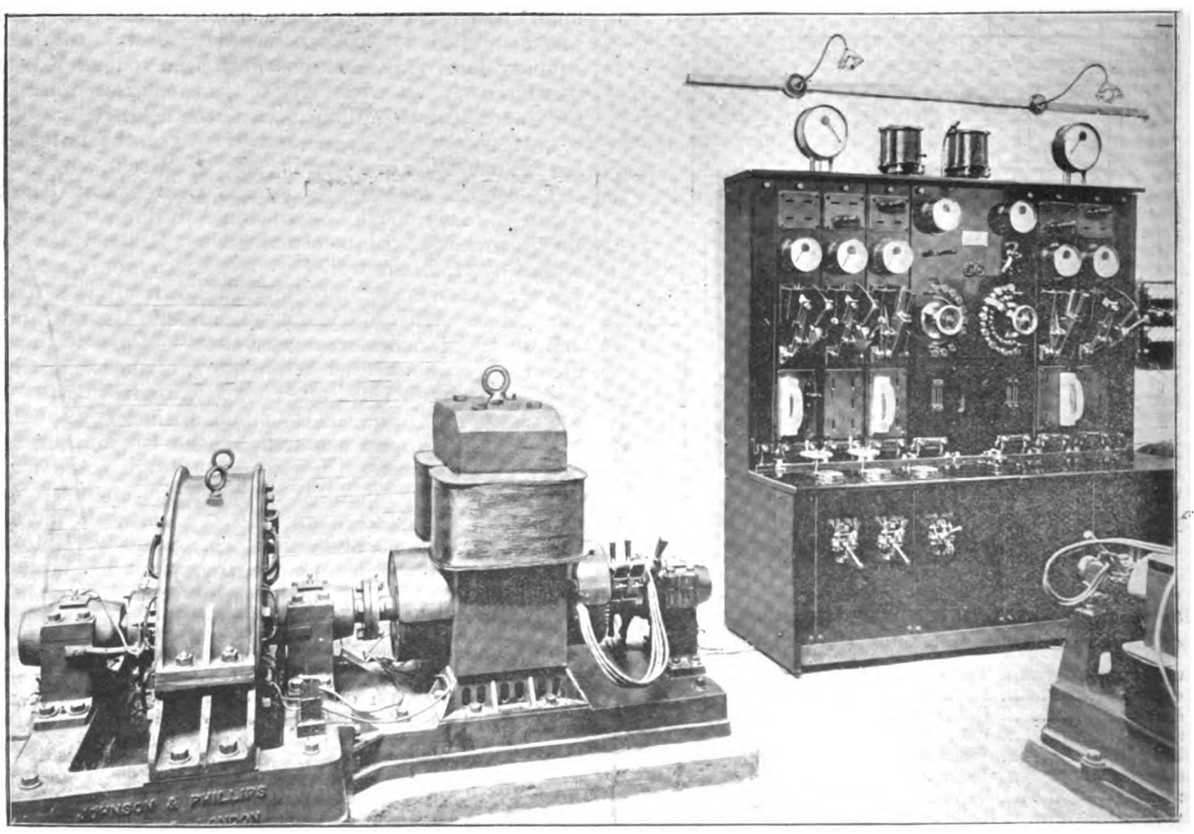

FIG. 2.—Switchboard and Motor-Alternator.

Digitized by Google

water is pumped through an oil filter, made by Messrs Haigh Bros., to the feed range for the boilers. There is also an injector of Messrs. Holden and Brooke's "Sirius" pattern as a stand-by, which is capable of delivering 12,000lb. of water per hour against the pressure of 125lb. to the square inch.

There are two sets of compound engines of 200 H.P., each coupled directly to Johnson and Phillips alternators (*see* Fig. 1), and having an output of 120 kilowatts at 200 volts and 50 revolutions per second. The engines are vertical, and were made by Messrs. Browett, Lindley and Co.; high-pressure cylinder 18in., low-pressure cylinder 22in., stroke 16in., and speed 200 revolutions per minute. The high-pressure cylinders have piston valves, and the low-pressure cylinders slide valves. "Begtrup" shaft governors of the latest form are employed, these, it is said, keeping the speed constant to within a maximum variation of 1½ per cent. in any circumstances. The engines are of the open type with cranks set at right angles; they are fitted with self-lubricating devices to all parts, and, in fact, are similar to the Browett-Lindley engines in other electric lighting stations.

A Johnson and Phillips 25-kilowatt motor-alternator, seen in Fig. 2, will, it is expected, suffice to take the whole load of the station after midnight, and to act as a stand-by to dispense with the necessity of employing the second large plant for slight demands above the capacity of one generator. It is run from a 56 cell battery, which it will charge at convenient times, running as a synchronous motor-generator. The machine runs at 600 revolutions per minute, and the alternator side has, of course, the same terminal pressure and frequency as the larger generators. The continuous side is a two-pole machine wound for 100 volts as a motor, and capable of giving 140 volts as a generator, for charging the cells.

The battery has been supplied by Messrs. Pritchetts and Gold. It consists of 56 cells in solid lead boxes, each cell containing 55 plates. The outputs are as follows:—

170 amperes for 9 hours.	273 amperes for 4 hours.
200 amperes for 7 hours.	420 amperes for 2 hours.

An ampere-hour efficiency of 93 per cent. is guaranteed. Each lead box stands in a wooden tray on oil insulators, and the trays are in turn supported on teak rails, which are arranged in two tiers so that there are two rows of cells on each side of the battery room, with a central passage between. The plates are supported by glass bearers, all plates, both positive and negative, being of the Planté type, and any one can be withdrawn and a new one inserted without its being necessary to stop the working of the cell in any way. The plates are kept apart by glass tubes, which are fastened together at the top, each plate having three tubes at equal intervals separating it from the adjacent plates.

The switchboard (*see* Fig. 2) has been manufactured by Messrs. Cowans, of Salford, and is of novel design. There are three machine panels, each of which contains a single-pole switch, fuse, ammeter and voltmeter, the other pole of the alternators being taken direct to another omnibus bar which can be connected to earth or not at will. A spare omnibus bar is provided, so that any machine can be run on either bar, and the feeders run in parallel or separate as desired. At present there are two feeder panels, one for the public lighting and one for private consumers; these have also a single-pole fuse, switch ammeter and voltmeter. All these panels are hinged at the bottom so that they can be swung forward to examine connections and automatically break contact on leaving the vertical position, so that each panel is "dead" and will remain so until restored to its original position. The synchronising transformers are placed on the top of the switchboard and make contact with their feet, two of which form the high-tension and two the low-tension terminals. The transformers can thus be instantly replaced by spare ones, without danger, should either or both fail.

There are two main high-pressure feeders, a 19/16 and a 7/14 cable, both lead-covered. They are laid in wood troughing which is filled in with pitch. An earthenware pipe runs alongside these two feeders to the end of the area proposed in the original scheme. The first scheme has, however, been considerably enlarged on, and cables have been laid into the residential districts, which, it is expected, will readily adopt the electric light. Owing to the fact that the houses are so scattered and the demand not sufficiently centred to allow of the laying down of a low-pressure network, the transformers are at present placed in the houses, except in some cases where the cellar of one of two or three adjacent consumers is made to form a small sub-station. The transformers were supplied by Messrs. Cowans, and have had special side boxes cast on to facilitate making the high-pressure connections. The mains—of which there are about four miles—are all of Messrs. Glover's diatrine type, concentric and lead-covered. The Wright maximum demand system of charging is employed, the prices being 7d. for the first hour's daily consumption and 2d. for remaining units. The street gas-lamps are being converted in every possible instance, and Reason fittings substituted in the lanterns, there being two 100 volt incandescent lamps connected in series for each pillar. This conversion of the gas lamps formed part of Messrs. Glover's contract. Transformer sub-stations are placed at suitable intervals to transform the current down to 200 volts, and a concentric main is taken up the interior of the post. At present there are no arc lamps, but it is expected that some will soon be erected in the principal squares and in the market place.

The whole of the work has been carried out under the direct personal supervision of Mr. Clirehugh, assisted by Mr. F. A. Cortez Leigh, one of the partners in the firm of Lacey, Clirehugh and Sillar, and Mr. Leonard H. Combe, the borough electrical engineer.

Our thanks are due to the above firm and to some of the contractors for assistance in the preparation of this description of the Eccles station.

THE WATER-POWER INSTALLATION AT PADERNO.*

BY G. SEMENZA.

(TRANSLATED BY JOHN R. DICK, B.SC.)

(*Continued from page 258.*)

Having thus shortly described the hydraulic part of the plant, we come now to the electrical part, and will consider, first of all, the general seheme of the installations which are supplied from the central station at Paderno. The current generated by the dynamos is transmited from the omnibus bars at the station directly to the line without the intervention of any transformers. The length of the line is 20 miles (with a branch going to Monza to furnish motive power and light to that industrious town), and it terminates at Porta Volta in Milan. The power house at Porta Volta is divided into two parts: a transformer station for the energy coming from Paderno, and a steam generating station. The transformers, as well as the steam alternators, supply three-phase currents at 3,600 volts and 42 periods. Hence they can be coupled to the same omnibus bars and help each other for the same supply. Porta Volta is thus the centre of distribution in Milan, which comprises three distinct services:

1. The distribution of energy for motors and lighting in the industrial portion of the city by an underground network with three-phase currents at 3,600 volts and a secondary network at 150 volts.

2. The supply for traction purposes with motor-generators placed in the new power house at S. Radegonda.

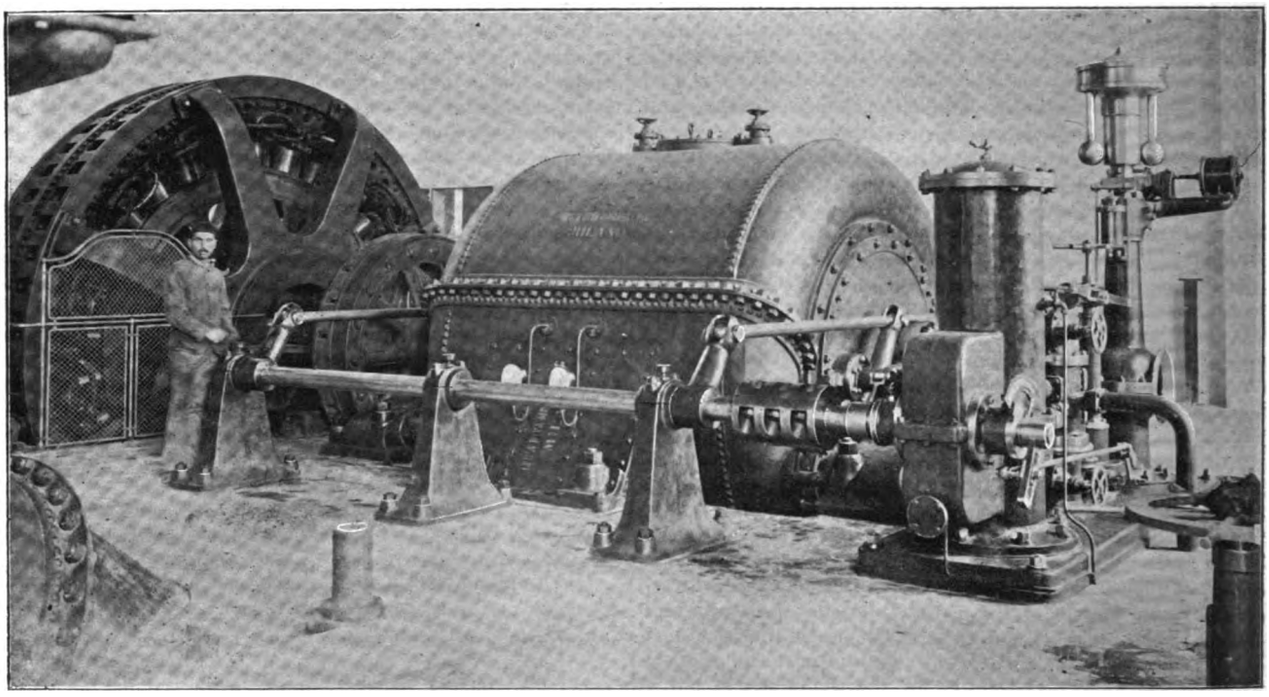
3. The supply of the old Edison network with continuous current by means of motor-generators placed in the same power house at S. Radegonda.

As regards the system of current, the different manufacturing firms presented proposals for three-phase, two-phase, and continuous current. It must be admitted that, so far as simple transmission without distribution is concerned, the problem within certain limits could be effectively solved by the use of continuous currents. But when one comes to distribution the conditions are changed; it is then necessary to use motor-generators, a solution technically and economically infinitely inferior to that of a system with alternating currents, and destroying all the advantages which are obtained in the transmission.

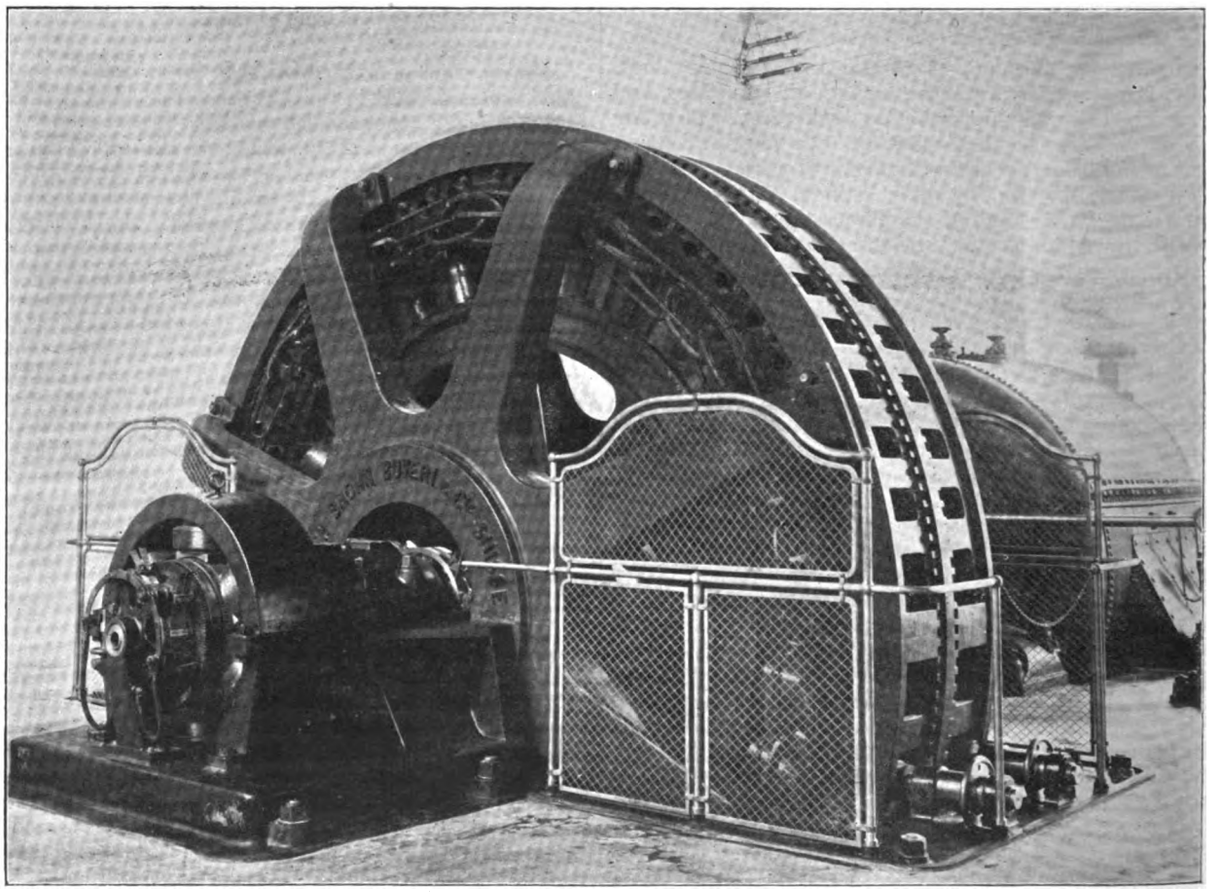
* Lecture given before the Milan section of the Associazione Elettrotecnica Italiana.

Digitized by Google

In an installation, which has to supply the varied wants of a large town, a subdivided distribution is now necessary. The choice between two-phase and three-phase was not such an easy matter two years ago as it is to-day. Then the two-phase system, supported by several manufacturers and defended by authoritative opinion, occupied a sufficiently strong position. However, the illusion being destroyed that with the two-phase system the joint supply for motors and lighting was easier, and it having been proved that the transmission was less economical, this system was definitely abandoned for the three-phase, which allows of a mixed supply equally well and perhaps better, and, being perfectly symmetrical in all its



2,160 H.P. Turbine direct connected to the Alternator.



2,160 H.P. Alternator, 13,500-15,000 volts.

Digitized by Google

parts, presents a system of distribution more uniform and more elastic.

The choice of the frequency of the current is a matter of the highest importance. After an installation is completed it is easy to change the pressure if it is not too high or too low, and to pass from two-phase to three-phase if the system is not satisfactory, but the frequency, when once the plant has been made, cannot be altered. It is now admitted that the best frequency is from 40 to 60 cycles per second, tending towards the higher limit for installations which are principally for lighting, and towards the lower limit for those in which the motor-load predominates. Our case was of the latter kind, and as the Edison Company already possessed an old monophase Ganz plant, on which were installed several hundreds of kilowatts with transformers constructed for 42 cycles, this frequency was selected. Already it has been proved that incandescent lamps and also arc lamps work in a very satisfactory way at this frequency.

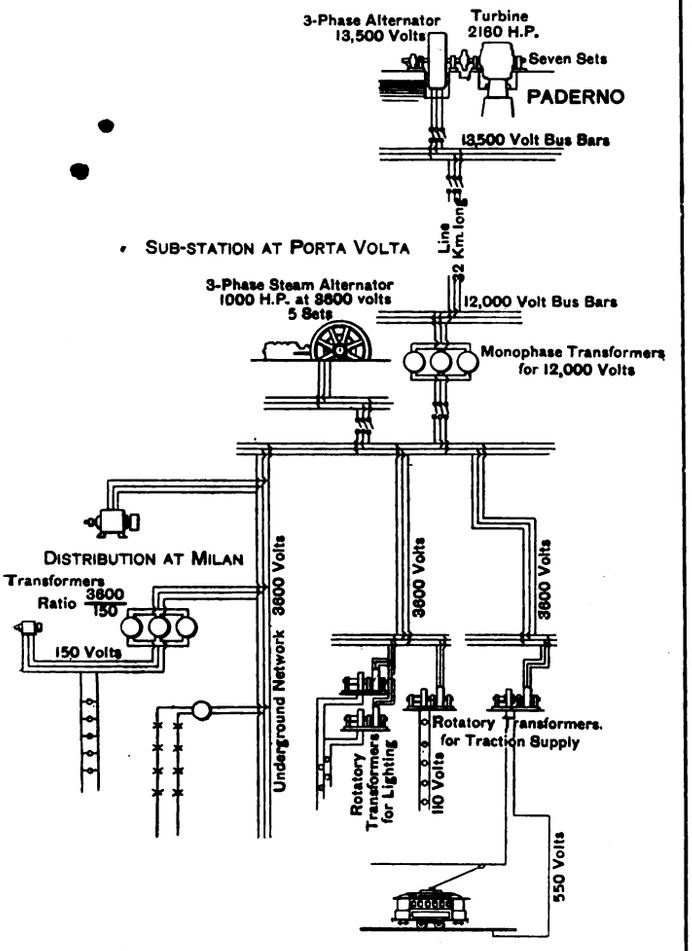


Diagram of System. Length of Line, 32 km.; No. of Wires, 18; Diameter of Wires, 9 mm.; Metallic Posts 60 metres apart.

The pressure may be chosen by superposing two curves, of which the one indicates how the outlay for copper is diminished with the increase of the working pressure, and the other how, with the same output at higher pressures, the cost of the machines, apparatus and insulation are increased. But this is an incomplete calculation, and it would be necessary for its completion to take into consideration the greater expenses of repairs and maintenance in the case of the higher pressure; and above 5,000 volts there is no experience available. For the installation of Paderno the pressure of 13,500 volts, generated directly by the dynamo, was decided upon. The direct production of the line pressure, and hence the elimination of transformers at the generating station, represents a large saving, and as the whole installation becomes very simple, the efficiency is higher, the attention required is small, and the cost of maintenance is trifling. It must be observed, however, that this was the first time that alternators of 13,500 volts had been spoken of. The question might be considered (1) from the point of view of the safety of working and of insulation which a 13,500 volt dynamo presents, and (2) under that of the efficiency of transmission, and finally under that of simplicity of the line.

When the generators of Paderno were first spoken of, there were very few dynamos at work whose pressure reached 3,000 volts. Some manufacturing firms had in their testing room machines for 10,000 volts, which had not been at work, and represented rather a type of laboratory apparatus than a dynamo machine. On the other hand, transformers of 15,000 to 20,000 volts were hardly in existence, and their safety was doubtful. And if it is possible to construct good transformers for 15,000 volts, why is it impossible to construct good alternators for 13,500 volts? As regards the objections which several manufacturing firms raised, most of them depended on their desire to follow, in the construction of machines for high tension, the same methods of construction as employed for low tension, while it should be remembered that a high-tension dynamo is a distinct type, quite different from that for normal tensions. As far as the line was concerned, it was necessary to have a pressure as high as 13,500 volts to obtain a satisfactory solution. In order to avoid a considerable skin effect, the diameters of the wires ought not to exceed $\frac{5}{10}$in. at a pressure of 13,500 volts, and to reduce the loss of energy to 9 per cent. 18 wires were necessary. With 10,000 volts and using 18 wires this loss would amount to 17 per cent., and to reduce it to 9 per cent. 36 wires would be required. Hence the solution with 13,500 volts was simple and economical, and, having the authoritative sanction of Prof. Ferraris, was boldly and deliberately selected. Precautionary measures were taken, however, and the plant was constructed so that, should any unforeseen phenomena arise causing a disturbance, the change to a much lower pressure would be possible without any alteration.

We may summarise the principal data of the three-phase alternator as follows:—The power absorbed is 2,160 H.P. or 1,590 kilowatts, the speed 180 revolutions per minute, the frequency 42 cycles per second. The difference of potential between the wires of the three-phase system is 13,500 volts.

The construction of the machines and of the switchboards was entrusted to the well-known firm of Brown, Boveri and Co., of Baden. The dynamo is of the type with fixed armature circuit, and a revolving field magnet having a number of pole-pieces.

Perhaps, someone may ask why this type was chosen in preference to the inductor type which was common in those days and also to-day, and I am glad of the opportunity to say a little on this point. The advantages of the inductor alternator over others are principally as follows:—The thorough mechanical construction of the revolving part, the abolition of rubbing contacts, the smaller consumption of energy for excitation with a higher efficiency. It is not necessary to stop to prove that these are real advantages; indeed, the fact of not having wires and coils carried round with considerable peripheral speed and exposed to the action of centrifugal force, which tends to damage the insulation, is in itself a very valuable thing. The abolition of rubbing contacts eliminates a source of trouble, which is by no means negligible. The saving in the excitation by the employment of a single coil instead of number of coils may increase the efficiency by 1 or 1½ per cent.

Let us now look at the disadvantages. Not mention the inconvenience of having an exciting coil of 16ft. or 18ft. diameter, we cannot attach too great importance to the fact that, as the iron is badly utilised, these machines are much heavier than others of equal output, and that in many cases this greater size may be very disadvantageous. Let us look next at the enormous leakage of magnetic lines and its effects. On examination of one of these machines it is clear that the external portion of the fixed part and the shaft of the revolving part are free poles of an electro-magnet. At light loads there are but few lines of force which pass through the shaft and supports instead of passing through the air-gap, but when the load increases, and gradually the internal reaction is felt, the lines which escape through the air assume

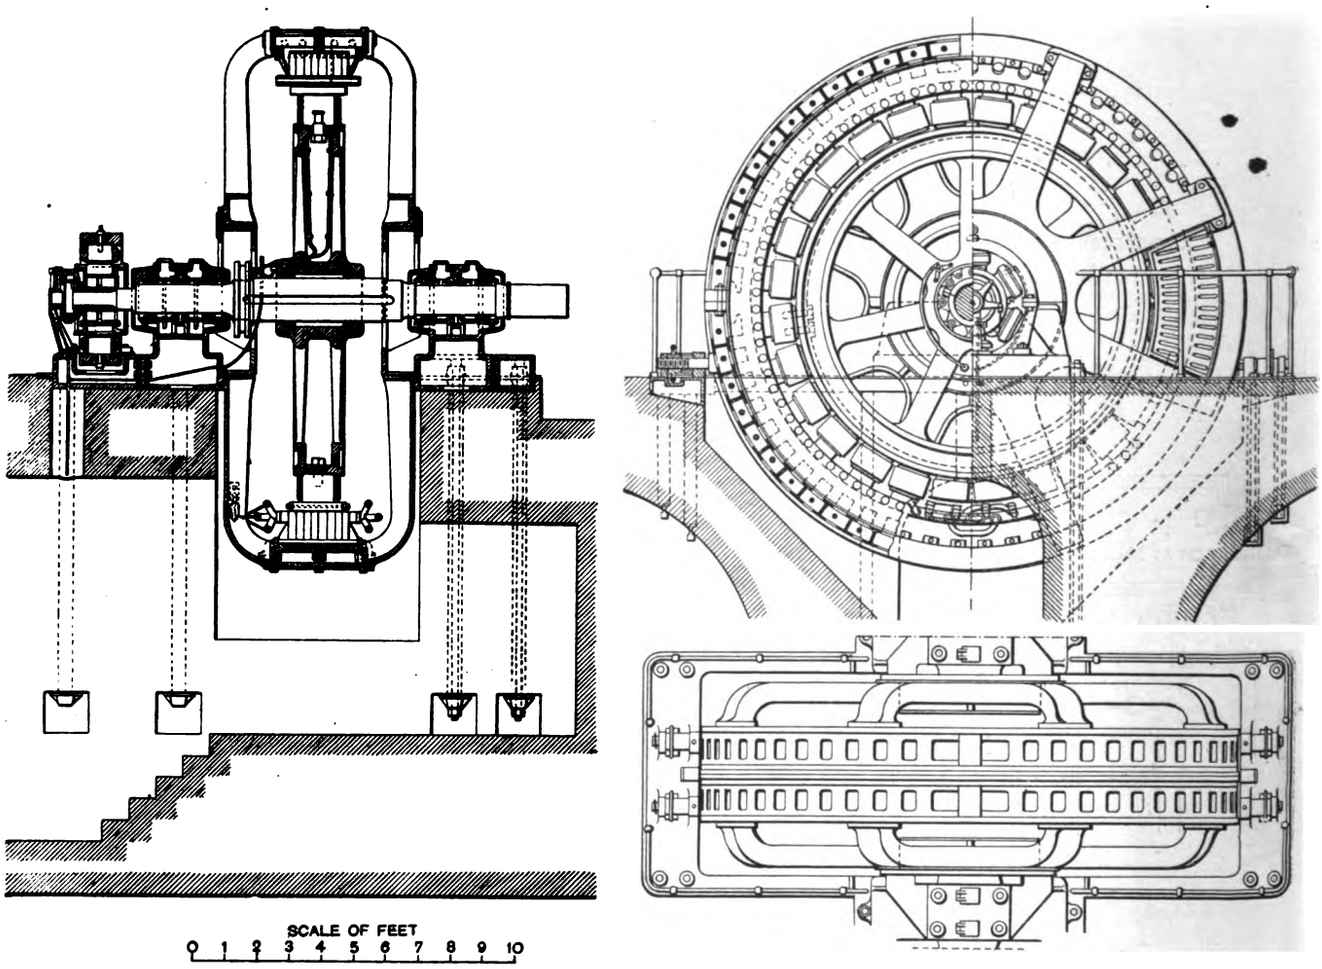
Digitized by Google

considerable importance, especially if the difference of phase is somewhat large. The proof of this is that all magnetisable objects near the machines are magnetised; for instance, it is necessary to make of bronze the regulators, governors and the parts of the steam engines which are directly coupled to the alternators. The number of leakage lines may become so great that on reaching a certain point it is impossible to increase the pressure, however much the excitation is increased.

To this, if to nothing else, should be attributed the non-success that almost all manufacturing firms have had to record against the machines first made of this type. The whole aspect of this phenomenon called internal reaction is very complicated, and its consequences are accentuated by the fact that in order to lessen the magnetic leakage, it is necessary to have a very small air-gap. In modern alternators it is essential to have a weak internal reaction, otherwise the joint supply of light and of power is impossible, and from this point of view machines with one revolving iron part, which may satisfy well enough the conditions for lighting only, are absolutely inferior to the others.

To turn now to Brown's alternator. It is a machine which at first sight presents a singular appearance. It seems to be composed of two parts which turn round, one inside the other. This form can easily be explained by observing how the internal construction differs essentially from all other machines of this kind. As a rule in the dynamo the fixed parts rest on wide lateral supports to which the bearings are attached. This machine on the other hand rests entirely on the bearings. To the inner side of each bearing is fastened a carrier having a cylindrical surface, and the armature ring is supported by several spokes joining on to a nave which is fitted to this cylindrical surface. This arrangement renders the manufacture simpler and has two special objects in view. The first is to ensure the perfect centering of the fixed part relatively to the revolving part, as everything can be adjusted by subsequently turning the bearing blocks; the second is to facilitate any repairs. In fact, should anything happen to the lower part of the armature it is only necessary to raise the bolts which are seen at the sides of the machine, and to turn the external part round the two cylindrical expansions of the bearings by means of a lever.

The revolving part presents some interesting features as well. 28 poles of cast steel are fastened by two bolts to its periphery. The winding of these poles is not made with wires or strip in the ordinary way, but is constructed as follows:—A flat bar of copper 0·157in. thick and 1in. to 1·18in. wide is wound into a helical form, the turns being insulated from each other by sheets of paper, and the resulting solenoid is compressed hydraulically. A winding is thus obtained which is very solid mechanically, and which does not suffer from the action of centrifugal force. The windings of the armature are passed through tubes of micanite paper. This method of winding is costly, and requires considerable labour, because the coils have to be wound on the machine itself, and have to be passed turn by turn through the tubes; but the use of an internal jointless tube offers great security with high pressures. These tubes project about 4in. from the iron, so as to prevent sparking between the wires and the frame, and the wires themselves are carefully separated by about 6in. distance. For this reason the machine is a great success, but all this care has to be taken in order to obtain an effective insulation.



Three-Phase Alternator.

Each alternator drives its exciter from its own shaft, which is the most economical and simple arrangement. It is true that direct coupling of the exciter has the inconvenience of increasing the variations of pressure due to the variations of speed. For example, as the speed diminishes the pressure will diminish proportionately, and the pressure of the exciter will also be reduced for the same reason, hence the total diminution of pressure of the alternator will be more than proportional to the variations of its speed. Nevertheless, in practice this is not a serious objection, especially if the internal

Digitized by Google

reaction is weak, and also because of the magnetic inertia of the machine. On the other hand, the use of separate exciters requires extra turbines, supply pipes and valves, all of which complicate the plant and increase the expense.

I have said that the internal reaction of this machine is feeble; in fact, it is guaranteed to be within 5 per cent. for a non-inductive load, and 16 per cent. for an inductive load, with a power-factor of 80 per cent. The promised efficiency at full load is 95 per cent. in the first case, and 93 in the second. These alternators are capable of absorbing the full amount of 2,160 H.P. with the above efficiency, when the power-factor is 80 per cent., and they can in this case furnish 80 amperes after running 24 hours at full load. This is what determines the size and power of the machine, and it is the only exact way of stating it. Any statement regarding the power, which does not take into account the power-factor, is absurd.

The method of fixing turbines and alternators in the dynamo room can be seen in the illustrations. The supply pipe passes under the alternator before reaching the turbine. This arrangement was made in order to keep the alternator quite clear of the water discharged, and to interpose a solid wall which would perfectly protect it from dampness, especially in times of flood. Besides, it makes it easier to carry the high-tension conduits from the machine to the switchboards, as these are fixed on that side of the dynamo. The dynamo room in itself does not present any great peculiarities. Great care was taken to secure a good natural ventilation by putting plenty of windows high up. An electrically-driven crane facilitates the operation of dismounting and repairs.

(*To be concluded.*)

WATERLOO AND CITY RAILWAY POWER STATION.

The opening of the Waterloo and City Railway by H.R.H. the Duke of Cambridge on July 12th last was probably the most important event in connection with electric traction in the year just closed. This line, which was described in *The Electrician*, Vol. XLI., p. 383, at the time of its inauguration, is the second completed underground electric railway in the world, that of the City and South London Railway Co. being the first. It possesses no intermediate stations, and was constructed essentially to give an express service between the Waterloo terminus of the L. and S. W. Railway and the centre of the City. We are enabled to give our readers this week a view of the interior of the power station which works this railway, and we are indebted to Messrs. Belliss and Co. for the photograph. The generating plant comprises six direct-coupled high-speed sets. Each set includes a 300 H.P. vertical enclosed Belliss steam engine, coupled to a Siemens 400-ampere compounded two-pole railway generator, working at from 500 to 550 volts. A specially designed switchboard occupies the major part of one end of the room, and is shown at the extreme right of the illustration. Steam is generated in a battery of six dry-back marine-type boilers, built by Messrs. Davey, Paxman and Co., the furnaces being stoked by the Vicars automatic coking stoker. We may add, in conclusion, that this power station is designed for a five-minutes' service of trains running at 25 miles an hour, each train consisting of four coaches, and having accommodation for 204 passengers.

IMPROVEMENTS IN MAGNETIC SPACE TELEGRAPHY.*

BY DR. OLIVER LODGE, F.R.S.

(Continued from page 309.)

PART III.

DETECTORS.

A large number of devices for improving the dectector of the fluctuating current at the receiving station were made and tried, and a few of them may be here described.

TONE TELEPHONE.

Not only was it considered desirable that the two circuits should be attuned to each other and to the sending dynamo or intermitter, but also it was thought well to make the receiving telephone so that it would only or chiefly respond to one particular note. I had found that the diaphragm of a Bell telephone need not be free everywhere except at the edges, but might nearly as well be fixed all over to a thin deal sound-board, upon which the ear was directly pressed. Consequently, I proposed to use this sound-board idea for a tone telephone. One good form is represented in Figs. 1 and 2, where F is the tuning-fork, screwed into a sound-board, E, with its prongs highly magnetised, and with a short iron electro-magnet, *c*, between its prongs, round which the received alternating currents were to circulate. The whole was mounted, in one form, Fig. 1, in a compact case, in general appearance like a Bell telephone, and the result was very sensitive to the proper note—distinctly more so than an ordinary telephone when both were in circuit. The ear was laid right upon the wooden end E, which holds the stem of the fork; and though, of course, the sound did not rise and decay quite sharply, yet signals could be clearly read, and the damping of the fork might be at any time increased, at the expense of a little sensitiveness, whenever sharper—*i.e.*, quicker—signals were wanted. Such a tone-telephone arranged on a large sound-board, or with a resonant jar, like Fig. 2, may serve as syntonic "call," accurately discriminating one station from another.

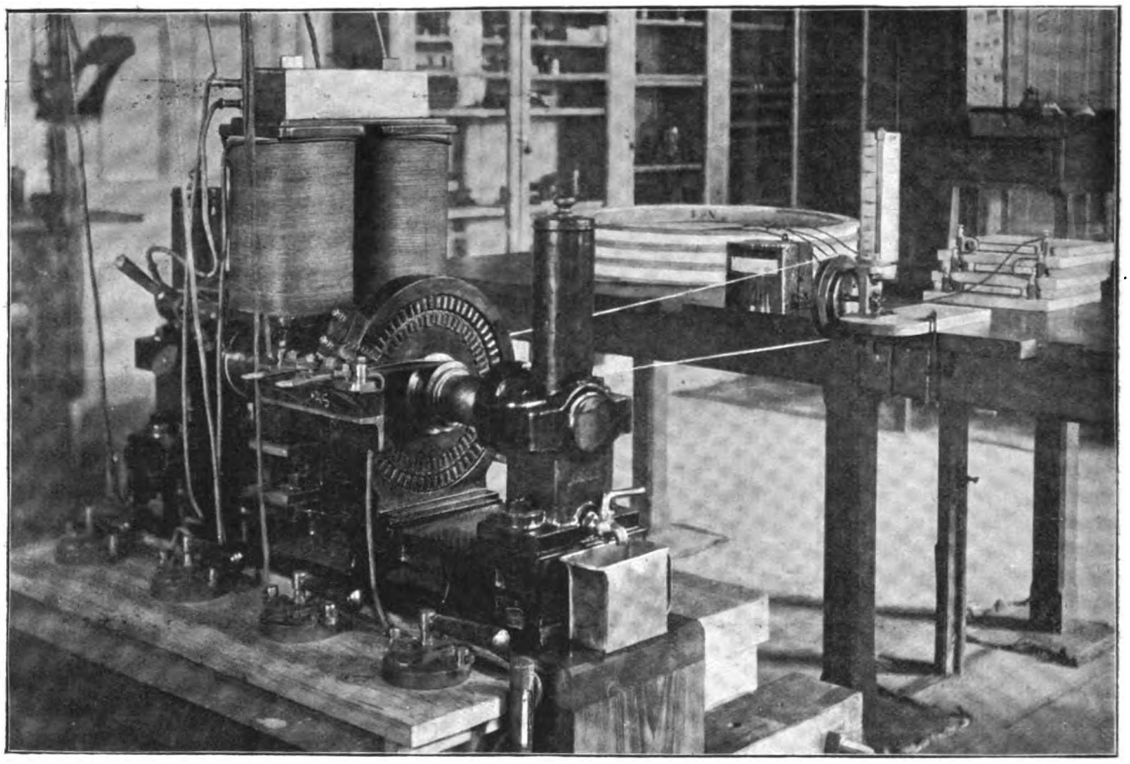
Another use for which a magnetised tuning-fork telephone is convenient is to serve as a weak local sender for the purpose of testing whether the receiving circuit is properly adjusted or not. Thus, for instance, suppose signals are expected from a distant station, and are not being received, it may be because the receiving circuit or its apparatus has gone out of tune a little; so its tone can be tested by twitching with the fingers the tuning-fork of a tone telephone whose local circuit is properly arranged in inductive connection with the main receiving circuit. It gives at each twitch a feeble alternating current, which should make the receiving instruments decidedly respond. If they do not, they must be adjusted till they do. Similarly, a local receiving fork-telephone may be used to test the adjustment of the secondary circuit.

COHERER.

Another totally different form of detector was suggested by my old experiment of the syntonic jars, where the air gap was filled by a pair of knobs in near contact, and with a local battery and bell—in other words, with what is now called a coherer circuit. So now the receiving condenser can be shunted by a coherer, and a relay worked by the signals so obtained. But to the sinuous disturbance of an alternator a coherer turns out practically insensitive; it is to electric jerks that it responds. Accordingly, when the sender is of the make-and-break kind a coherer answers; but when it is of the slowly alternating kind it fails.

COHERER CALL.

By inserting an interruptor I in the receiving current so as to jerk any induced sinuous current that it may find there, the coherer C can be made to work, and one plan of its connections is shown in Fig. 3. It may not at first be apparent why there should be two condensers, S S, in series in this figure, but it must be remembered that the interruptor must not be allowed to affect any portion of the local battery current; else, of course, the coherer will respond when no signals are being sent. A is the receiving coil, R a relay and B a bell.



†FIG. A.—Photograph of the small high-frequency Alternator made for Dr. Lodge by Messrs. Chas. Parsons and Co., Newcastle; driven by motor on same shaft and reaching 3,000 per second.

† The Figures A, B, C, &c., are not referred to actually in the Paper itself, but served, in the form of lantern slides, to illustrate Dr. Lodge's remarks at the Institution on December 8th.

BOLOMETER.

A bolometric call was also tried, and was found to work, but, as it was not specially successful, the details of it will not be given.

VIBRATING COIL TELEPHONE.

For the purpose of disturbing a sound-board, and in general of producing a mechanical effect in solids or liquids, as opposed to gases, it was thought probable that an iron diaphragm was not the best plan, but that the whole receiving coil might be mounted so as to be itself capable of vibration in a strong magnetic field. An early form of the vibrating coil telephone and sound-board is shown in Fig 4, where M is a large horse-shoe magnet with perforated pole-pieces, one of which carries a sound-board E with a stretched wire from its middle passing right through the perforations to a screw tightener H, and carrying, rigidly

* Paper read at the Institution of Electrical Engineers, Dec. 8, 1898.

Digitized by Google

attached to its middle, a light fine-wire coil, C, matted together with shellac, and placed between the pole-pieces. The magnet was magnetised, not in the customary way, but with its adjacent poles of the same sign, so that the lines of force

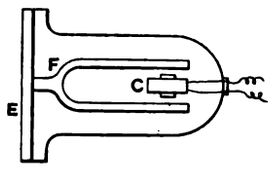


FIG. 1.

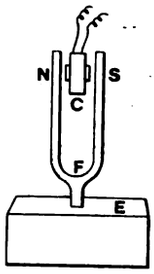

FIG. 2.

spread out through the coil, and gave it the chance of cutting them rapidly if it moves at all axially. On passing feeble alternating currents through the coil the sound-board was strongly affected by

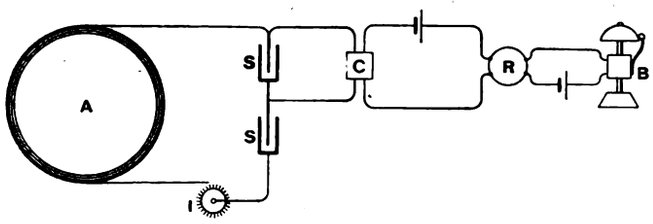

FIG. 3.

its taut wire. A subdivided iron core was subsequently placed in the coil, but, whether by reason of the increased mass, or for some other reason, it did not now work so well.

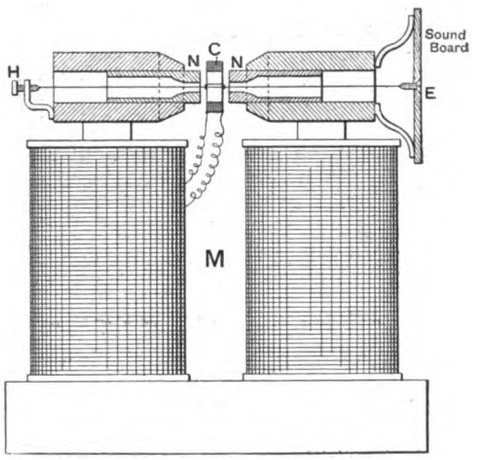

FIG. 4.

Another form was then made with a magnet specially designed as shown in Fig. 5. All the iron was well annealed, plenty of field winding put on, and the air gap was an annulus $\frac{3}{8}$in. square in

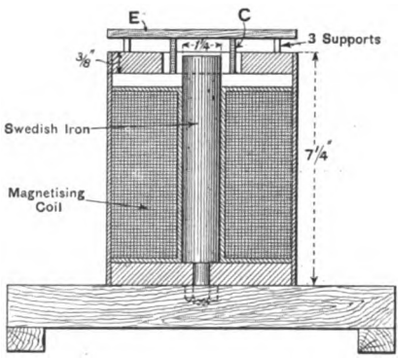

FIG. 5.

section and $1\frac{1}{2}$in. in diameter; no attempt was made to subdivide the iron, because in this arrangement it is plain that eddy-currents are all to the good. They do not occur in any moving part, so their chief effect is to diminish the impedance of the receiving coil. The coil is powerfully damped by the strong field, and a certain strength of field is, therefore, best. The coil was cemented direct to a wooden disc, and the thicker this disc the higher the note to which the arrangement most powerfully responded. By placing the ear on the wood, the first-made instrument on this plan was exactly as sensitive as the best of the usual patterns of telephone—for instance, the Collier or the Ader pattern.

Tambourine membranes and many other plans were tried for holding the coil, but the simple wooden sound-board answered best.

The wooden disc need not be clamped at its edge. It has a circular nodal line, and in three points on this circle it was usually clamped so that it could vibrate freely like a circular sort of harmonicon reed. Thus mounted it was very sonorous, at least before the coil was put on. The load of the coil had to be taken into account in finding the nodes, and they were accordingly found experimentally. When the plate was unloaded its nodal line was at 0·68 of its radius, which agrees with theory. The loading, however, spoiled all this and greatly increased the damping, so that considered as a syntonic receiver it was not successful. The coils at and time were of copper, and heavy. Now they are of aluminium, this much lighter.

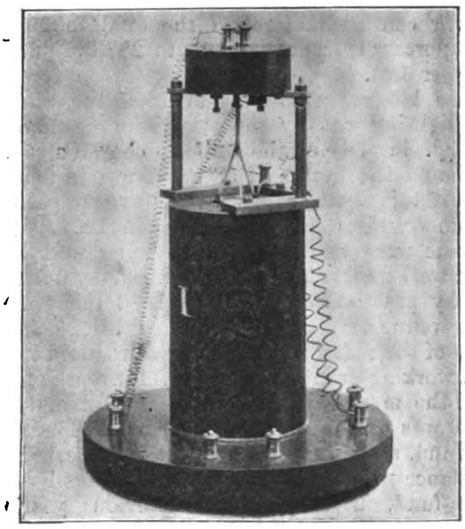

FIG. B.—Photograph of Single-pole Electromagnetic Magnifying Telephone, with suspended coil and extra large microphonic transmitter for strong currents. Compare Fig. 5.

The present plan of a large soundboard, and a light coil rigidly attached to its middle by either a light wooden tripod or a light cone, was then designed, and has not been improved upon.

(*To be concluded.*)

An American Lighthouse.—It is announced, says the *Western Electrician*, at Marquette, Mich., that experiments will be conducted by the government at that point in the use of electricity in lighthouses. A submarine cable has been shipped to the local electric light and power company, and it will be laid to the lighthouse on the extreme end of the breakwater in the lower harbour. The lantern in the lighthouse will be fitted with a concentrated-filament stereopticon incandescent light of 50 c.p., five times the candle power of the kerosene light which is now in use. But the increase in brilliancy is a secondary object. In the spring and autumn gales waves frequently sweep the breakwater from end to end; and it is a matter of much peril for a man to traverse 3,000ft. of breakwater in order to light the lamp. The first 1,000ft of the breakwater is capped with a concrete superstructure which has a tunnel running through it. That far the cable will pass thorough the tunnel and be throughly embedded in cement. For the remaining 2,000ft., which is not capped by a superstructure, the cable will pass over the top of the breakwater, being held in its place by cleats. It is this part of the course which necessitates the use of a submarine cable, because heavy seas constantly break over it in storms. Here would have been a good opportunity for a short-distance trial of Mr. Tesla's wireless power transmission system.

ELECTRICITY WORKS ACCOUNTS.

Aberdeen Municipal Electric Supply Works.

The first of our two analyses this week deals with the accounts of the second and third years of working of the Aberdeen Municipal undertaking. As well be gathered from a comparison of the two years' figures given in our table, the progress of the concern both in the matter of output and increased economy of working was well maintained in 1897.

Of the total authorised capital of £52,000 at December 31, 1897, £45,086 had been received, while of this latter sum £2,155 had been repaid out of the sinking fund. The total capital expenditure amounted to £48,423, representing £79·3 per kilowatt capacity of generating plant in the station; the amount expended during 1897 being £11,802. The capacity of the plant in the station had, during the year, been augmented by 180 kilowatts, thus raising the total generating capacity to 610·8 kilowatts. As regards the custom—corresponding to an increase in the equivalent 8 c.p. lamp connection of 17 per cent., which raised the total to 29,635, the output has increased from 210,185 to 287,072 units sold, or about 32 per cent.

During the latter six months of 1897 the charges for current for lighting was by the maximum demand system from 6d. to 3d., in place of the uniform charge of 5d. which, during 1896 and the first half of 1897, was in force. As a consequence of this change, the average revenue per unit sold dropped from 5·18d. in 1896 to 4·77d. in 1897. Although the 1896 costs were very satisfactory, being well below the average, the works costs have been reduced by 0·3d. and the total costs by practically 0·5d. In 1896 the works costs bore to the revenue a ratio of 51·1 per cent., in 1897 this ratio was, in spite of the reduction in the tariff, reduced to 45·5 per cent., and a working profit made of £3,111, representing 7·32 per cent. of the mean capital expended. Out of this gross profit £1,150 was paid in interest on loans, £768 allocated to the reserve fund, and £1,024 paid into the depreciation fund, leaving a balance to the good of £169, which has been carried to a reserve fund, out of which the previous year's deficit was paid.

It may be interesting to note that the sum of £1,024 paid on account of depreciation was arrived at under the following scale of depreciation charges on the respective items of capital expenditure:—Buildings 1 per cent., machinery 5 per cent., accumulators 5 per cent., mains and services 1½ per cent., electrical instruments 2½ per cent., and meters 5 per cent.

The progress of electricity supply at Aberdeen since the commencement is shown by the following table:—

Year.	Quantity generated B. T. U.	Sold public lamps.	Sold private consumers.	Total sold.	No. of public lamps.	Price per unit.
1894 ...	71,921	6,169	58,843	65,012	10	7d.
1895 ...	159,777	8,257	130,115	138,372	10	6d.
1896 ...	236,649	11,057	199,128	210,185	14	5d.
1897 ...	317,552	15,310	271,762	287,072	22	5d., 6d., 3d.

Cardiff Municipal Electric Supply Works.

Started in December, 1894, the Cardiff supply undertaking has completed its third year of working, the accounts of which form the subject of our second analysis this week. It should be noticed that the first year in our table ends at December, 1896, while the second year dates from March 31, 1897, and ends at March 31, 1898. The authorised capital at this latter date was £59,835, and the total amount borrowed and received was £32,500. The sinking fund stands with a balance of £2,621 for repayment of loans, of which £31,146 was at 3 per cent. and £1,354 at 3½ per cent. interest. The total capital expended at March 31st last amounted to £62,430, representing £142 per kilowatt of plant capacity.

Owing to the non-delivery by the contractors of a 300 kilowatt generating set, which should have been in place more than a year ago, the progress of the business has been severely handicapped, with the result that the lamp connections during 1897-8 were only the equivalent of 2,976 8 c.p. lamps, representing an increase of 21 per cent.

The output for 1897-8 was 357,193 units sold, as compared with 308,430 in 1896, being an increase of about 16 per cent. It is rather interesting to note the somewhat high ratio of the output to the plant capacity which obtains at Cardiff, in spite of its having an alternating-current system of supply with, therefore, no batteries nor motor load. In this respect it may be likened to the Portsmouth and Tunbridge Wells loads where this ratio was, in 1897, of the values 37 and 23·7 respectively, as compared with the mean of most of the alternating current supply systems in operation, viz., about 18 units per 8 c.p. lamp capacity of plant. Take, again, Bristol with its good proportion of arc lighting, but with an output for 1897 of not more than 19 units per 8 c.p. lamp capacity of plant as compared with Cardiff's 26 and Portsmouth's 37, and we are constrained to the conclusion that arc lighting supplied from the usual incandescent lighting plant in the station must prove of great advantage to an undertaking.

Costs at Cardiff have been sensibly reduced during the last year chiefly through economies in generation items which, collectively, have dropped nearly 0·5d. Management and property charges have risen, however, with the result that the total costs show a drop of not more than about one-third of a penny, the figure for 1897 being 2·97d. per unit sold—a not abnormal value considering the embarrassment occasioned by the delay in the plant extensions and the cost in wages of running the rectifiers in a sub-station a mile away from the central station.

We are very pleased to see that the undertaking has attained a self-supporting stage, in that instead of a deficit, as was the case in 1896 to the extent of £548, a profit of £61 was made, after paying £1,667 as interest on loans, and £848 to the sinking fund.

We shall look forward with pleasure to further decreases in the costs at Cardiff when the arc lighting rectifiers, hitherto installed below the Town Hall, shall have been removed to the central station in Canton, and when the present plant extensions permit of the normal expansion of business.

In 1895 the output was 175,078, and the maximum load 275 kilowatts, while at the end of that year the equivalent lamp connection was 9,330 8 c.p. lamps, and the number of consumers 108.

The following is a list of electric supply works the accounts of which have been analysed, together with the dates on which statements and analyses of accounts have appeared:—

ABERDEEN.—REMARKS—* The sinking fund has been absorbed in repayment of loans, but there is a reserve fund distinct from the sinking and depreciation funds which amounted to £253 in 1896 and £429 in 1897. *a* Inclusive of £901 on accumulators, £1,631 on electrical instruments and £2,057 on meters. *b* Over-expended. *c* Includes insurance, £13, and bad debts, £19. *d* Inclusive of £1,655 on accumulators, £1,702 on electrical instruments and £3,055 on meters. *e* Includes insurance, £20, and bad debts, £6. *f* Met by the reserve fund. *g* Paid into the reserve fund. *h* By the maximum demand system. This scale superseded the even charge of 5d. per unit, as in 1896, at the middle of 1897.

CARDIFF.—REMARKS—*a* Over-expended. *b* Being to insurance. *c* Includes £16 paid for management of stock and composition duty; this deficit is met by the district rate. *d* Includes auditing £25, and insurance £61. *e* After deducting £24 to management of stock and composition duty. *f* By maximum demand system.

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal 1861—1878).

Published every Friday, Price Sixpence; Post Free, Sixpence Halfpenny

Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone: 949 Holborn. *Telegrams:* "Electrician Newspaper London."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "The Electrician," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "The Electrician" *Printing and Publishing Company, Limited, and be crossed "Coutts and Co."*

All Editorial letters to be addressed to The Editor.

All letters for insertion in "The Electrician," *or containing questions, must be accompanied by the name and address of the writer as evidence of good faith. No notice whatever is taken of anonymous communications.*

"The Electrician" is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices, as above.

New Volumes of "The Electrician" *commence in April and October.*

Subscription Rates.—The Rates for Subscriptions to "The Electrician" are as under:—

	Year	Half-Year	Quarter	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d	Post free, payable in advance.
Postal Union ..	30s. 0d.	16s. 0d.	8s. 0d	

"The Electrician" *offers exceptional advantages to Advertisers.* It has by far the largest circulation of any English Electrical paper, and circulates all over the World. *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

Trade Advertisements *intended for the current issue must reach the Office not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday. Wrapper Advertisements by Wednesday morning.*

Official Announcements, Auctions, *and* Small Advertisements *accepted up to 6 p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct o "The Electrician" *Printing and Publishing Company, Limited. The well-known* "Electrician" Series *of Standard Electrical Works at present consists of—*

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young, M.I.E.E. Price 10s. 6d., post free; abroad 11s.

THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By Messrs. H. K. C. Fisher and J. C. H. Darby. Price 6s. net; abroad, 6s. 3d.

BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH. Edited by C. E. S. Phillips. With an introduction on the history of Crookes Tube and Röntgen Ray work, and a chapter giving "Practical Hints," on the subject.

THE POTENTIOMETER AND ITS ADJUNCTS. By W. C. Fisher. Price 6s., post free.

LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS. By F. C. Raphael. Price 5s., post free.

MOTIVE POWER AND GEARING. By R. Tremlett Carter. Price 12s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson. Price 12s. 6d., post free.

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. Fleming, M.A. F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. **Vol. I.** Price 12s. 6d., post free 12s. *Vol. II. is nearly ready.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. Fleming. VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. New Edition. Price 12s. 6d., post free. VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. 93 original illustrations, price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. Snell. 10s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. George Gore. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. Weymouth. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By Gilbert S. Ram. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Gruphl and H. M. Kilgour. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d., post free. New edition in the press.

"THE ELECTRICIAN" PRIMERS. In Two Vols. Paper covers, 2s., post free, 2s. 2d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d.

WIRELESS TELEGRAPHY: Signalling across Space without Wires by Electric Waves. By Dr. O J. Lodge. Enlarged Edition. Price 2s. 6d. net.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c. By A. C. Curtis-Hayward, B.A. Price 3s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont. Price 3s. 6d., post free.

FULL CATALOGUE POST FREE ON APPLICATION.

"ELECTRICIAN" SERIES FORTHCOMING BOOKS.

ELECTROMAGNETIC THEORY, VOL. II.—By Oliver Heaviside. The second volume of this important work is in an advanced stage, and will be ready shortly.

PRACTICAL TELEPHONY.—By Dane Sinclair and F. C. Raphael.

PRIMARY BATTERIES.—A work on this subject will shortly be published, bringing the theory and practice of the Primary Battery up to date. The book will be fully illustrated.

SECONDARY BATTERIES.—By E. J. Wade. Fully illustrated. The Author in this work will deal briefly with the theory and fully with the chemistry, design, construction and manufacture of secondary batteries or accumulators.

"THE ELECTRICIAN" WIREMAN'S POCKET-BOOK.—"The Electrician" Company will shortly publish a valuable pocket-book for the use of those engaged in wiring work, both external and internal.

CARBONS FOR ALL ELECTRICAL PURPOSES.—By Francis Jehl. A work will shortly be published dealing fully with the manufacture of carbons for all electrical purposes. The book will illustrate the machinery and apparatus used in carbon manufacture on the Continent and in America, and will give the latest practice in this important subject.

SPECIAL NOTICE.

With this issue of "THE ELECTRICIAN" is published the large Sheet Table of Electrical Supply Undertakings of the United Kingdom, which all purchasers of the Paper should receive gratis. Complaints of non-receipt should be promptly made to THE PUBLISHER.

NOW READY.—Vol. XLI. of "The Electrician," bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

A complete set of the Second Series of "The Electrician" can now be supplied. These sets are very scarce, and early application should be made.

1898.

The commencement of a New Year once more gives occasion for a brief review of the progress in electrical industry and science during the past twelve months. It is pleasing to note on every hand a steady advance, and abundant indications that both in theoretical science and in industrial applications electricity is still making rapid strides. As the new century looms nearer and nearer it becomes more apparent that electricity is, as it were, the key note, whether for researches into the true-inwardness of physical and physico-chemical phenomena, or for improving the material conditions of modern civilisation. Even in biological science electrical action is held to explain much of the physical aspect of that inscrutable mystery—Life; and in the practical side of biology, in medical and surgical treatment, the value of electricity is being increasingly recognised. Thus, throughout a wide range of the scientific and practical life of to-day, electricity, in one aspect or another, is playing a part that constantly assumes greater importance; and the promise that the new century will inaugurate an "Age of Electricity" was never so sure as it is at the present time.

Casting a glance backwards over the events of the year just closed, we may first notice those which relate to the more practical side of electrical affairs. The leading character of all these, we think, is reflected in three conspicuous events—the engineering strike, the Parliamentary inquiry into the law of electric generating stations, and the Parliamentary inquiry into the telephone question. The triad may appear ill-assorted, yet it is not so incongruous as at first sight appears. Although the engineering strike belongs more especially to the previous year, it was not actually terminated until well on into 1898, while its evil influence and disastrous consequences have been stamped on British industry ever since, and are not soon to be eradicated. Since the termination of the strike there has been an enormous accession of work in the engineering manufactories of the country; large and small contractors

Digitized by Google

alike have had their hands full, have been working continuously on double shifts and overtime, and yet have dismayed their customers on all sides by protracted delays in fulfilling contracts. This activity may or may not be encouraging, according to whether it is to be permanent or only transient; but it is beyond dispute that British manufacturing industry is suffering appreciable loss of prestige through the disappointment and want of confidence engendered by the delays. We hope manufacturers will speedily awake to this stern fact and, by endeavouring to restore the confidence of home and foreign customers in the promptness and reliability of British work, stem the tide of orders that has set in in the direction of foreign manufactures. Fortunately, it is not too late, for the present activity in home engineering manufactures reveals that a large bulk of customers are still determined to have British goods. Another deplorable effect of this delay in executing orders is noticeable in some of the electric supply stations that are waiting for the delivery of plant. Where the delay involves postponement of the opening of a new system of supply, as at West Ham, the case is bad enough; but in many other instances it is far worse, the over-loaded station being unable to keep the requisite pressure on its mains, and hourly running the risk of breakdown of its insufficient plant. The unusual number of temporary interruptions to electric supply that we have regretfully recorded this winter must, we fear, be laid primarily at the door of those fatuous individuals who promoted the engineering strike. Precisely the same mischievous influence on British electrical industry threatens to result from the opposition of *doctrinaire* and purblind socialists to the adoption of the recommendations of the Parliamentary Committee in regard to the law of electric generating stations. The history of this matter may be written in a very few words: the Electric Lighting Acts, as they stood, discouraged and even debarred companies from obtaining powers to supply power in perpetuity over extensive areas, the recognised practice being to acquire powers for 42 years for a limited area controlled by some one local authority, which might acquire the undertaking at the end of that time. Parliament appointed a Select Committee to enquire whether the disability might be removed, and the Committee advised that it should be. But the mania for owning and working public undertakings, instead of wisely governing them by judicious bye-laws, had so taken possession of local authorities that these bodies fancied they saw in the Parliamentary recommendation a distinct injury to their own local interests. Hence a deal of ignorant opposition has been raised, and threatens to be still more vigorously pursued this year, against a method of generating and supplying wholesale electric power that could not fail to be fraught with many benefits to the industries of this country. Another evil effect of this mischievous socialism—which unhappily is making a playground of electrical undertakings—is to be seen in the recommendations of the Telephone Committee, a body of men as biassed and unfair in its methods and judgment as the Select Committee just referred to was the reverse. We hold no brief for any telephone company, nor do we especially advocate that the telephone system of this country should be carried on in the manner it is at present; but we strongly protest against the doctrine which is so readily taken for granted in certain journals and official quarters, and by a large section of the general public, that a national telephone system can be efficiently worked on the basis of local government ownership and control. The control should be coextensive with the system itself; and, in our opinion, none better than that which might be administered by the Post Office is to be had from any existing organisation.

During the past year a considerable number of new electricity works, whether for supply or for traction, have been put in operation, and several important extensions to already existing works have been made. The new electric supply works started comprise those at Wakefield, Morley, Stockport, Colchester, Eccles, Salisbury, Cork, Lincoln, Folkestone and the village of Mardy; and new stations have been started in connection with the already existing systems at Belfast, Hull and Glasgow. New electric traction undertakings which have been completed and put in operation during the year comprise the underground Waterloo and City Railway, and surface tramways at Glasgow, Liverpool, Bradford, Halifax, Kidderminster-Stourport, Middlesbrough-Stockton, Laxey-Ramsey and Cork. Besides these undertakings there are several works on the eve of completion; and it will be seen from the large supplement sheet Table of Electric Supply Works for 1897-8, which we publish this week, that a further very large number of undertakings in this class will be completed during the early months of this year. In a corresponding supplement Table of Electric Railways and Tramways, which we hope shortly to publish, it will be shown that electric traction progress and prospects are not less bright. Indeed, there are indications of an extensive field for the labours of British electrical engineers, that will keep them occupied for a long while to come, if they and the vast body of workmen employed by them use aright the opportunities presented to them.

Theoretical science must always be regarded by the practical and commercial mind as the handmaid of applied science. It is, therefore, fitting that, having briefly surveyed the present position of applied electricity, we should turn to see what advances have been made in scientific discovery and research, and what promise these hold out of immediate improvement in practice. We are aware that the theoretically-minded professor is apt sometimes to disclaim any practical intention in his researches. By way of retort, we would point to the alacrity with which he hastens to the Patent Office whenever, by any chance, his researches prove to be of practical value. "Science for its own sake" is a very laudable thing to pursue; but we could wish that a greater proportion of scientists would allow their researches to be influenced by the practical problems and difficulties of applied science. There are numerous obstacles that the man of leisure and means, and with a mind capable of scientific research, might greatly help engineers to surmount. We need enumerate only a few of them: We want a more durable, efficient and less heavy secondary battery; we want a glow-lamp filament combining higher efficiency with a life at least as long as it now has; we want to know more about the iron to use for our transformers and dynamos; about the possibility of obtaining energy direct from carbon without heat; about the chemistry of the application of electricity to new industrial processes and manufactures, and so on. Wireless telegraphy is a happy exception to the all-too-prevalent custom of scientists to ignore the practical value of research; it has enlisted the services of numerous leaders of physical science, and now that so many able minds are engaged upon its problems, a really practical, commercial solution should not be far off. The empyricism that apparently has characterised the practical experiments in this direction needs to be replaced by systematic and scientific investigation as to the best means of propagating the waves and collecting their energy, and as to the most satisfactory way of doing what is now so unsatisfactorily done by the coherer. Doubtless Prof. Oliver Lodge's Paper, recently read at the Institution of Electrical Engineers, and the discussion which is yet to

Digitized by Google

take place upon it, will go far to instil a scientific spirit into the practical work that is being done, as well as to acquaint the professors with the practical difficulties presented in actual operations. It cannot be said that in any other branch of scientific work, besides research in wireless telegraphy, has pure research contributed conspicuously to practical advance in electricity during the past year. An important scientific movement, however, should not pass unnoticed, viz., the proposal to establish a national physical laboratory. In August, 1897, the Treasury appointed a Committee to consider this scheme; the members of the Committee were Lord RAYLEIGH (Chairman), Sir COURTENAY BOYLE, Sir ANDREW NOBLE, Sir J. WOLFE BARRY, Prof. W. C. ROBERTS-AUSTEN, Mr. ROBERT CHALMERS, Prof. A. W. RÜCKER, Mr. ALEX. SIEMENS and Prof. T. E. THORPE. A report was presented in October last (*The Electrician*, Vol. XLI., p. 780), and it was proposed to establish a national laboratory as an extension of Kew observatory, under the control of the Royal Society. No further developments have yet been disclosed.

It is our sad duty, in conclusion, to record that the hand of death has been laid with unusual severity on the ranks of the electrical profession, and its immediate friends, during the past year. Among the distinguished personages associated with electrical enterprise who have passed away are included Lord SACKVILLE ARTHUR CECIL, the Earl of SUFFOLK AND BERKSHIRE, Sir A. B. FORWOOD, Sir JOHN FOWLER and Sir J. N. DOUGLASS. The tragic death of Dr. JOHN HOPKINSON, through a disaster in the Alps, will be fresh in the memory of every member of the electrical profession, which has also been deprived of LATIMER CLARK, CAMILLE A. FAURE, Dr. C. E. EMERY, and NELSON PERRY. A historic personage disappeared with the death of DE MERITENS, in Paris; and the names of Dr. E F. A. OBACH and O. B. SCHALLENBERGER will also be remembered as being among those who contributed to the early development of electrical industry. Telegraphists will miss many from their ranks, including Major ALEX. WOOD, Capt. W. H. DAVIES, JAMES BROWN, J. W. JAQUES, W. T. NEWITT, R. S. HAMPSON, G. K. WINTER and W. F. O'BRIEN.

ELECTRICITY SUPPLY WORKS COSTS IN 1896 AND 1897.

Since March last year, when the more detailed analyses of electricity works accounts—as they now appear in these pages—were commenced, we have dealt with most of the important electric lighting undertakings of which we have been supplied with data, and in this, the first number of a new year, it may not be either inappropriate or uninstructive if some attempt be made to glean from the accrued data and records some general conclusions regarding the progress made in the economy of generation and supply of electricity during the two years generally dealt with in such analyses of accounts as have appeared.

Having in view the differences in the management, the administration and the rendering of accounts of undertakings worked by local authorities and those worked by companies, we have considered it more useful and satisfactory to separately consider and compare the results of working under the two *régimes*. In the following tables and curves reference to undertakings which have not been in normal operation for fully two years has been avoided, so as to maintain a legitimate basis of comparison, and, for a like reason, has been omitted such stations the analyses of which have referred to periods other than one year.

Municipal Electric Supply Works.—In Table I. are set out the more interesting particulars and results of working of 33 municipal stations during 1896 and 1897. Although in the majority of cases the financial year ends with March, we have, for convenience, adhered to the practice of terming the years ending at March 31, 1897 and 1898, respectively 1896 and 1897. There are two columns in this table, adduced from the figures given in our analyses, which we have considered of sufficient interest to include with the usual costs data—viz., the columns headed "Load Factor" and "Total Costs plus 6 per cent. of Capital." The former gives for each undertaking and year of operation the percentage ratio of the output (in units sold) to an output equal to the maximum demand on the station continued without intermission during the whole of the year referred to; in other words, it gives the percentage ratio of the actual output (in units sold) to the maximum demand (in kilowatts) multiplied by the constant 8,760—the number of hours in the normal year. The other column referred to has been introduced in an attempt to facilitate a fairer comparison of the financial results of working of the several undertakings by taking account of the capital charges upon the revenue as well as the costs of working and management. To do this we have assumed 3 per cent. as a fair average rate of interest on loans to municipalities, and 3 per cent. of the expended capital to cover depreciation and the repayment of loans. At the bottom of the table the averages for the years 1896 and 1897 of the 33 undertakings referred to is given, with the per cent. increase or decrease (as the case may be) of the average values during 1897, as compared with the previous year. The record costs, &c., of the list are shown in heavy type.

Manchester, of course, heads the list as regards output, both in 1896 and 1897, but it is singular to find Portsmouth—an alternating station, with, therefore, a very moderate, almost negligible motor load and no batteries—having a higher output compared with the plant capacity, that is "plant load factor," than Edinburgh in both years. This is, no doubt, due to the large rectified current arc lighting load on the ordinary plant. Portsmouth also possessed the highest load factor in 1896, but Edinburgh, with its increasing motor load and arc lighting, crept into the enviable position in 1897 with a load factor of 13·8 per cent.

It is, no doubt, largely in consequence of its position in this respect, as well as its large output, that Edinburgh carries record lowest wages at the station in 1897, and in both years the lowest generating costs, works costs, management, property charges, total costs, and, what is more important, stands in the place of priority in the column representing the total costs plus the estimated capital charges. It is to be also noticed that, bearing the lowest figure in the table for average revenue per unit and by no means the highest percentage of working profit, Edinburgh has justly given the benefit of the economical working of the electricity supply undertaking to the patrons of the department.

As regards fuel costs, Stafford shows the lowest figures in the list for the two years, though in 1897 this item had risen to 0·32d., as compared with 0·242d. in 1896. In 1897 Worcester shares with Edinburgh the satisfaction of the lowest management and property charges in the list, though, needless to say, the signification of such a record is far greater as regards the latter undertaking, since it has so many other low records to boast of in the matter of costs. It may be observed that the average costs, revenue per unit sold, and ratio of costs to revenue have substantially decreased during 1897 as compared with 1896. The items of cost showing the largest decrease are those of oil, waste, water, &c., the average of the 33 stations on the list being for 1897 0·143d., as compared with 0·18d. for 1896, a drop of nearly 26 per cent. Management and property charges is a collective item which also bears evidence of increased economy. On the other hand, it is interesting to note that the *records* of the list respecting fuel, generating costs, works costs, total costs, and the ratio of costs to revenue, all show an increase for 1897 over the 1896 records of the list.

As indicating the influence of capital expenditure on the true financial position of a concern, the following little table (II.) is instructive. The six undertakings in each year having the lowest figures in the last column of Table I. are arranged in order of priority in this respect, together with the total costs per unit, the expended capital per kilowatt of capacity, the

output, and the figure representing the units sold per 8 c.p. lamp capacity.

It will be noticed that in both years Edinburgh had, to a high degree and in combination, the conditions for low total charges on revenue. It combines the lowest total costs with a low capital expenditure and a high "plant load factor," as measured by the ratio of units sold per 8 c.p. lamp capacity. The result is that the low figure of 8·38d., representing the estimated total charges in 1896, have been improved upon in 1897 by 2·87d. per unit. Thanks chiefly to its low capital expenditure and high plant load factor Glasgow camesecond in 1896, but Manchester and Brighton, with lower total costs and increasing plant load factor, ousted it from this position, and compelled Glasgow to take fourth place in 1897. Portsmouth's working costs and high capital charges prevent its taking a higher position than fifth in spite of a high-plant load factor.

In Figs. 1 and 2 are given nine curves, showing the relation between the various items of cost and output per annum. These have been plotted from the mean of the data, irrespective of the year, of the 33 municipal undertakings included in Table I. Naturally, for outputs higher than about 1,200,000 units sold, the points on the curves are dependent on

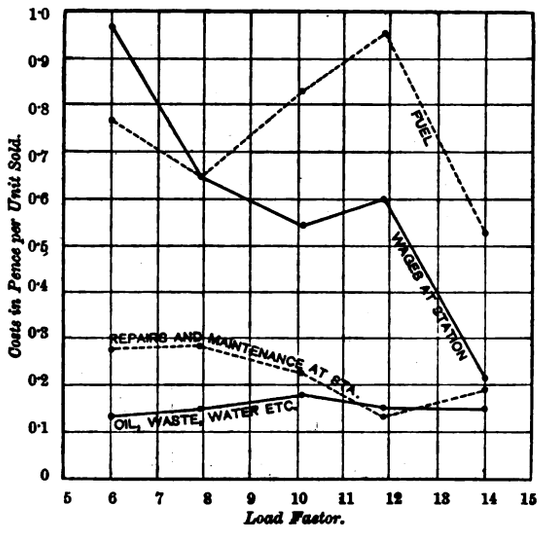

Fig. 3.—Municipal Undertakings.

the mean of two concerns at most, and two points, viz., those representing the data for the outputs, 1,993,000 units and 3,435,000 units are dependent alone on the 1897 results at Brighton and Manchester respectively. In spite, however, of this paucity of data for the high outputs the trend of the curves is sufficiently decided and consistent to justify their careful study. As might be expected, the curve of wages at the station is the most decided in its fall with increased output, while repairs and maintenance at the station, and oil, waste, water, &c., are practically constant.

Fuel costs per unit also has a decided but slight fall, and we should have expected the management and property charges curve to have come out somewhat steeper.

As to the curves of generating, works and total costs, they tell their own tale in no uncertain language, and it is interesting to mark their sensitiveness at outputs below about 600,000 units. It may be interesting to know that the values

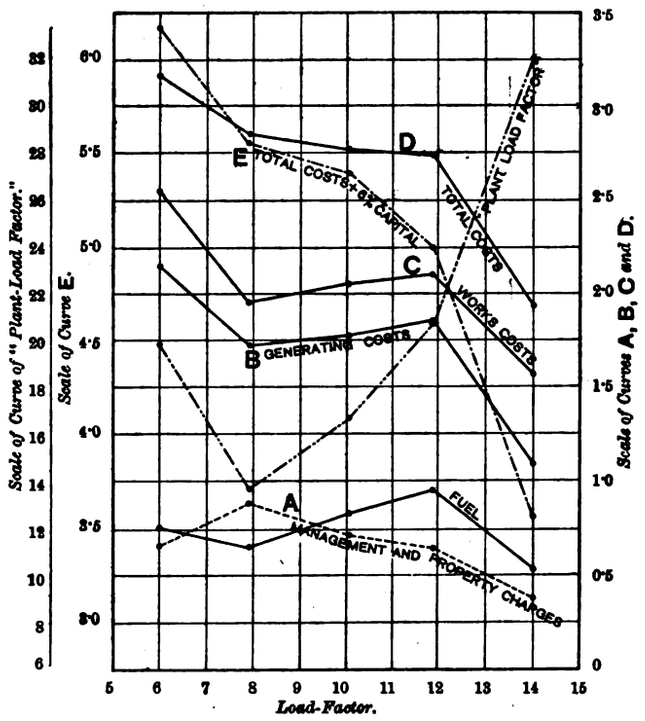

Fig. 4.—Municipal Undertakings.

for the various points for the output, 2,702,000 units sold, are the means of the Edinburgh 1897 and the Manchester 1896 working.

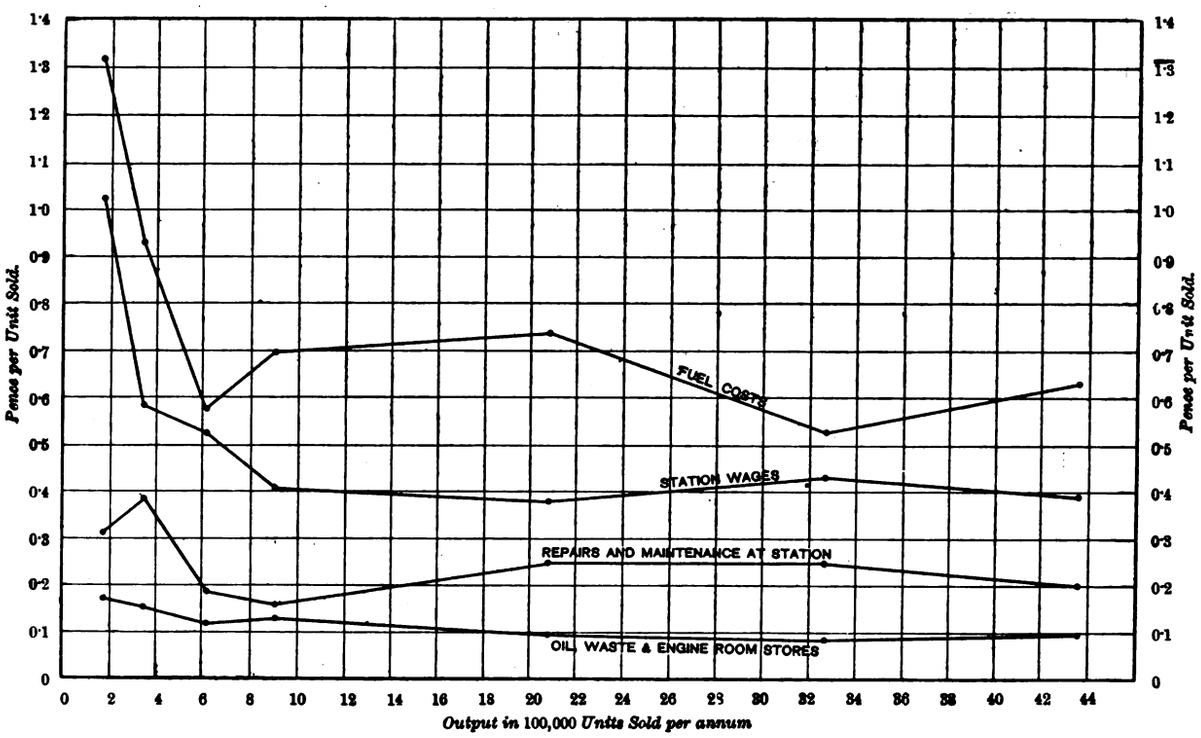

Fig. 5.—Company Undertakings.

Figs. 3 and 4 give the curves connecting the various costs with the load factor. Here, again, in Fig. 3, the station wages item shows the most decided fall as the load factor increases; repairs and maintenance, however, appear to show a more sensitive relation to load factor than to output, while fuel seems more indifferent. Turning to the curves in Fig. 4,

there is no mistaking the influence of load factor on total costs, and especially on total costs plus capital charges.

Electric Supply Undertakings worked by Companies.—Table III. gives particulars of the working, during the years 1896 and 1897, of 25 undertakings worked by companies. As in Table I. the record values of the list are in heavy type, the corresponding values in the columns of wages at the station, repairs and maintenance at the station, generating costs, and distributing costs, have not been so picked out as these cost items have not been separately rendered in the accounts supplied us in the case of the towns left blank in these columns, viz., Leeds, Norwich, Birmingham and Hove. In the last column of the table are given the several figures obtained by adding to the total costs per unit an amount equal to 7 per cent. of the capital expended in pence per unit. We have considered it more in accordance with prevailing conditions to assume 4 per cent. as the rate of interest payable for capital when raised by companies as compared with the 3 per cent. assumed in the case of local authorities; the remaining 3 per cent. is, as before, intended to represent the charges on account of reserve funds.

In respect of output Westminster heads the list, and in 1896 had the highest ratio of output to generating plant capacity, but in 1897 the Charing Cross concern came out highest in this latter respect, and was also blessed with the highest load factor in both years. Of the 25 stations noticed in the list the Charing Cross —greatly to its credit as a London concern— stands with the lowest total revenue per unit sold in 1897. In this respect the Newcastle and District undertaking runs the Charing Cross Co. very close, having held the lowest figure in the list for 1896. In both years Leeds shows the lowest fuel, works and total costs, and also the lowest ratio of costs to revenue. As regards total costs the Leeds 1897 figure of 1·54d. is very closely run by Sheffield with 1·55d. per unit; in fact, these are the only two undertakings in the table with total costs below 2d. per unit.

Although Leeds total costs are well below the St. James and Pall Mall with 2·29d. and 2·23d. per unit the latter concern has, with a very slightly higher total revenue per unit, been able to show working profits in 1896 and 1897 respectively of 13·9 and 16·2 per cent. of the mean capital expended, as compared with the Leeds corresponding figures of 11·5 and 9·8 per cent. In this connection the last column in the table has an important signification, and Table IV. (p. 373), shows the six concerns with lowest values for total costs plus 7 per cent. of the capital expended, and is interesting, including, as it does, some other data having a bearing on the ultimate financial positions.

In 1896 it will be noticed that, although the Newcastle and District concern had the same total costs as St. James's, and a considerably lower capital expenditure per kilowatt capacity of plant, yet, in consequence of the latter's much higher "plant load factor," as expressed in units sold per 8 c.p. lamp capacity, its probable total charges on revenue, including capital charges, are lower, being as 3·98d. is to 4·29d. per unit. If we care to pursue the reason further, we find that although the St. James's "plant load factor" is higher than—

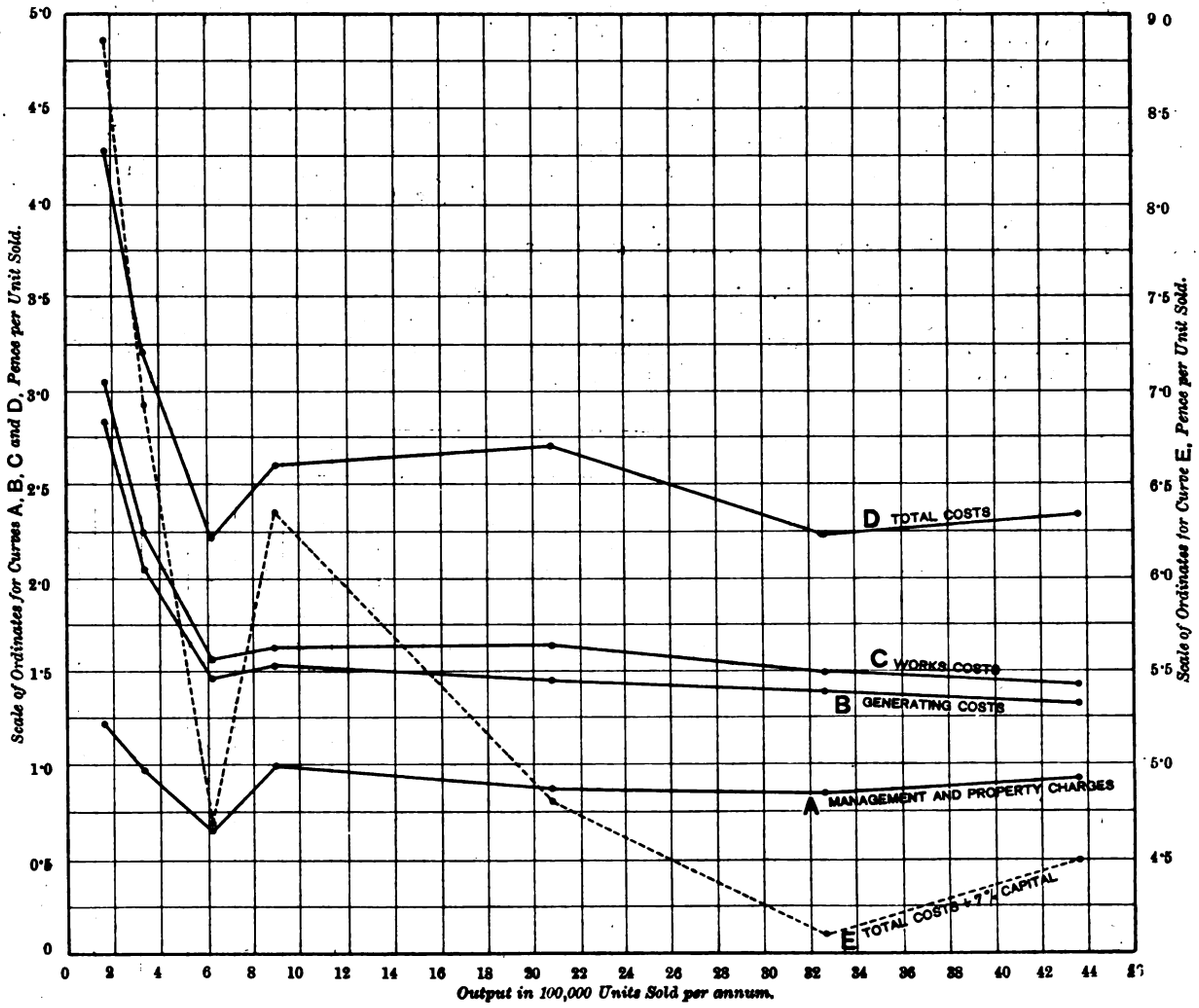

FIG. 6.—Company Undertakings. Connecting Costs per Unit with Output.

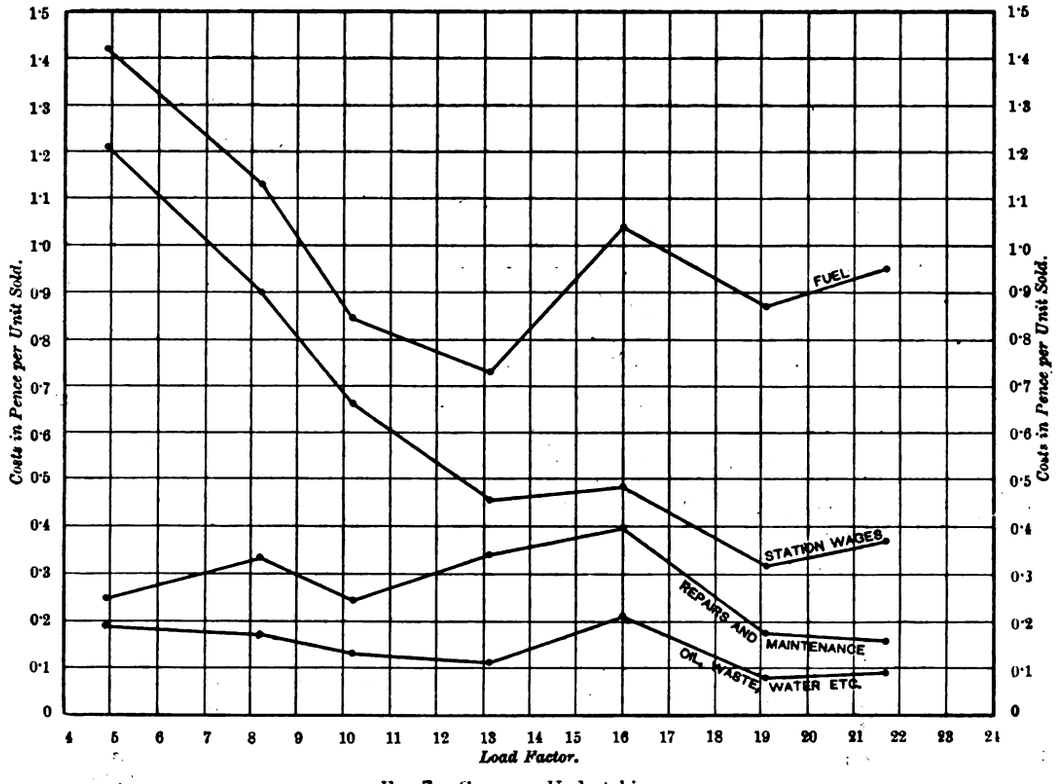

FIG. 7.—Company Undertakings.

Digitized by Google

even double—that of the Newcastle and District, it is not because the load factor is higher—the reverse is the case. We are driven to the conclusion that there was a much larger proportion of reserve or spare generating plant in the Newcastle and District station than in the St. James's stations, since the batteries used in the latter are probably inadequate to the effect we are considering. Since the total costs and the capital expenditure at Leeds were much less than those of the St. James's; the difference in the plant load factor here again causes the difference in the total ultimate charges on the revenue. In this comparison, however, we must note that the St. James's has a higher load factor than Leeds.

Let us make another comparison, this time between St. James's and Westminster. The latter's "plant load factor" and capital expenditure per kilowatt are both higher, the total costs are slightly lower, but the total costs plus the estimated capital charges are higher, and in this case purely in consequence of the larger capital expenditure per kilowatt.

Passing to the 1897 results, we find the St. James's keeps its place of priority and has, further, improved upon its 1896 figure, and we find a stranger (to this little list) has crept into the second place, viz., the Newcastle-on-Tyne undertaking, by virtue of a not excessive capital expenditure and a good "plant load factor"—the total plant capacity in the station being very slightly in excess of the maximum demand. Norwich comes third in the list, and Sheffield, with the lowest total costs of the six, has to take a fourth place on account of its rather high capital expenditure.

It is interesting to observe that Charing Cross, even with its enviable load and plant load-factor, has to be omitted from the table, being seventh, on account of its rather high capital outlay; while Leeds had, in 1897, to take eighth place, on account chiefly of its low plant load factor.

Sufficient has now been said to show the paralysing effect of idle plant or, more generally, idle capital on the ultimate financial position of supply undertakings, and the figures in Table IV. are significant of the influence which the consulting and designing engineer may exercise almost equally with the resident engineer responsible for the more apparent every-day costs of working.

Figs. 5 and 6 graphically indicate the relation, so far as the data of our analyses to date afford, of the various costs to output. It should be noted, however, that in these curves and those relating costs to load factor, their consistency is somewhat marred by the fact that the data for the high outputs as well as the high load factors are, in the majority of cases, furnished by London concerns where the load is met by two, three or four separate stations, each of moderate outputs, and where, moreover, the conditions of working and of capital expenditure entail higher costs than elsewhere. It is necessary to bear this in mind in studying these curves, as their

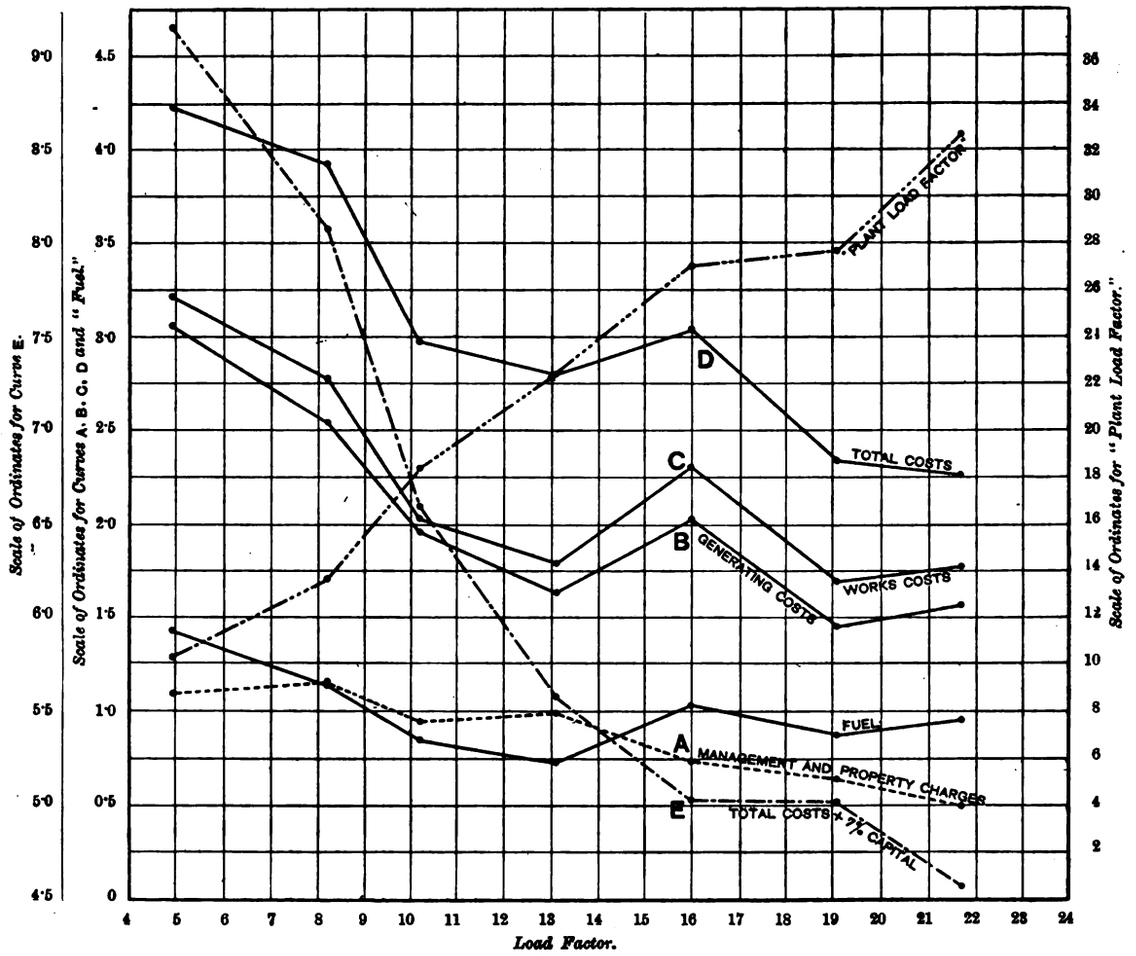

FIG. 8.—Company Undertakings.

significance is thereby somewhat strengthened, and the rise to be noticed at the right-hand end of most of the several curves explained.

Figs. 7 and 8 indicate the corresponding relationship between various items of cost and load factor. Considering the narrow limits of the latter, the curves are very consistent in their signification. The line of "plant load factor" has a slight, though an empirical, interest.

In conclusion, we might add that, had it been possible to place the various items of cost of working and supply by municipal and company undertakings upon an even basis of comparison, there is no doubt that the averages, being less influenced by the abnormals, would result in even more representative curves and figures; but, as things are, and especially since the Board of Trade form of rendering the accounts under the two conditions differ even in slight degree, we believe that the results given above are likely to prove more instructive than otherwise rendered.

CARBONS FOR ELECTRIC LIGHTING AND OTHER PURPOSES.*

BY FRANCIS JEHL.

(Continued from page 303.)

Engineers have devoted a great deal of time to this question during the last 30 years, and their experiments have been so far successful that it is possible at the present day to build a furnace or system of furnaces which give very economical results, as nearly all the heat created can be effectually utilised.

If we investigate the conditions and requirements necessary for the baking of electric light carbons, &c., we will find that many of these conditions are practically the same as those necessary for baking high-grade ceramic articles. We find that in both cases one of the most important conditions in order to attain success is that the heating of the furnace should be very gradual, and that the rise in temperature should only proceed by small degrees, not by jumps, as the goods will warp or get contorted. The cooling must likewise be gradual, or else there will be many breaks and cracks. The heat of the furnace must also be evenly distributed, as otherwise we shall obtain an uneven and irregular quality of ware. The nearer we can fulfil and accomplish the above principal conditions, together with that of a high temperature, the more satisfactory and perfect will be the quality of the carbons when baked.

In glancing over the history of the numerous experiments that were made with furnaces of different design in connection with the pottery industry, we find that on the whole two great strides were accomplished—first, in the construction of the "ring furnace system"; and, secondly, that of the "chamber furnace system."

To Herr George Mendheim, of Munich, one of the most celebrated furnace engineers of Germany, is due the credit of inventing the ingenious gas ring and chamber systems of furnaces that are in wide use on the Continent. Mendheim's experience extends nearly two score years back, and it may be mentioned that he was the first to convert and adapt the ring system of furnaces so that they could be worked with gas, thus making them applicable for use in the better branches of the pottery industry. Formerly it was impossible to use them on account of the articles getting soiled by the soot and smoke that was caused by direct heating or combustion of the fuel in the furnace itself. No doubt Mendheim's experience with the ring system, and the information he imparted to his friend H. Escherich at the time, resulted, to some extent, in the construction of the well-known Escherich gas-ring furnace.

When the carbon industry began to flourish, in the eighties, some of the keen-witted manufacturers in Germany soon saw that the chamber or ring systems of furnace, mentioned above, were the only kinds to use in which economical and commercial results could be obtained in connection with the carbon industry, and it was not long before they had such systems in their works. It is almost impossible to believe that, after all these years of experience, there still exist some carbon manufacturers that have neither a ring or chamber system in their works. These manufacturers use principally ovens that are known under the name of "periodical half-gas furnaces," which are, as has already been explained in the chapter on carbons, very uneconomical in every respect when used for carbon manufacture.

Saving and economy in fuel, gradual increase of the intensity of heat, and gradual cooling of the wares can only be effected commercially in furnaces of the chamber or ring systems, as they work and are heated *continuously* and not *periodically*: at the same time the heat of the finished goods is utilised and won back again by allowing the air that is necessary for combustion to pass through the finished chambers, thus getting heated up in a similar manner as in a regenerator, while a gradual cooling of the carbons takes place.

In Figs. 36 to 38 we have various views of a Mendheim furnace that contains 18 chambers. The gas generators are shown at *a a*, and it will be noticed that they are somewhat similar in design to that shown in Fig. 34. The gas coming from the generators flows into the passage *b*, and thence either into the passage d_1 or d_2, according on which side of the furnace the chamber that is heated is situated. There are two valves, c_1 and c_2, by which the gas can be turned into either passage d_1 or d_2. From these main gas passages branches extend that lead under each chamber of the furnace system, as designated in the Figs. by e_1. Let us suppose that chamber VII. has just been finished and that we are going to start chamber VIII. In the first place the gas from the generator flows only along the passage d_1 as the valve c_2 is closed while c_1 is opened. The valve *e* of the branch passage e_1 at chamber VIII. is opened, and the gas flows into the passage as shown clearly in the transverse sectional view. It will be noticed that the floor of each chamber contains a large number of openings, seen in the plan at chamber I. These openings are just over the dividing partitions of passages *m* and *n* (clearly seen in the transverse section), at right angles to the passage e_1. The smaller passages *n*, it will be seen, communicate with the gas passage e_1, while the larger passages that supply air, communicate with each chamber by means of the openings *f f f*, in the walls between each chamber as shown in the plan and longitudinal sections. From the above explanation it will be seen that air and gases meet and mix at the openings in the floor of the chamber, and burn when they issue from it, while the gases resulting from combustion leave by way of the flues *f f f*, into the next chamber, and so on into the passage g_2 as shown by the arrows in the longitudinal section. From the passage g_2 they enter and circulate through the chambers X. to XV. and then into the flue *i*, by way of valve *h*, which is raised. Now the chambers IX. to XV. are filled with carbons that are to be baked, and it will be seen that the heat of the gases that result from combustion is absorbed in the chambers through which they flow, and by this means a gradual heating of carbons takes place. From the flue *i* the gases escape into the chimney *k*. The communication between chambers XV. and XVI. is barred by means of sheet-iron dampers placed at the entrances of the passages *f f f*, so that the combustion gases can only pass out at *h* into the flue *i*, and up the chimney.

The air that supplies oxygen for the combustion that is going on in chamber VIII. enters first into the furnace by way of chamber XVIII., as the entrance to that chamber is open; flows through the passage g_1, into chambers I. to VII., and then first into VIII., where it is wanted. The dotted arrows shown in the plan represent the air path, while the arrows drawn in full lines indicate the path that the combustion gases take. It will be seen that as chambers XVIII., I. to VII. have already been finished, and contain a great deal of heat, the air in circulating through gets heated up to a high temperature, so that when it arrives in chamber VIII. it may be as high as 600°C. to 700°C. This permits us to obtain a great heat in the combustion chamber, and, in fact, about 1,500°C. can be obtained (when using the system invented by Mendheim), at which carbons ought to be baked. Also the fact that the heat of the combustion gases as they pass out of chamber VIII. into the others, where that heat is taken up by the carbons, &c., makes this furnace system one of the most economical yet invented. The fact that over 200 Mendheim chamber furnaces exist in Europe, among which are some in well-known carbon works, speaks for itself, and the work he did for the pottery industry is now keenly appreciated by the best carbon makers on the Continent.

The chamber XVI. in the meanwhile is getting filled with fresh goods, while from XVII. the finished and cooled ones are taken. When chamber VIII. is finished with carbonising, the gas is turned off at e_1, and on at the corresponding valve at IX. The dampers at XV. are removed and placed in position in chamber XVI., while the same is done with reference to the

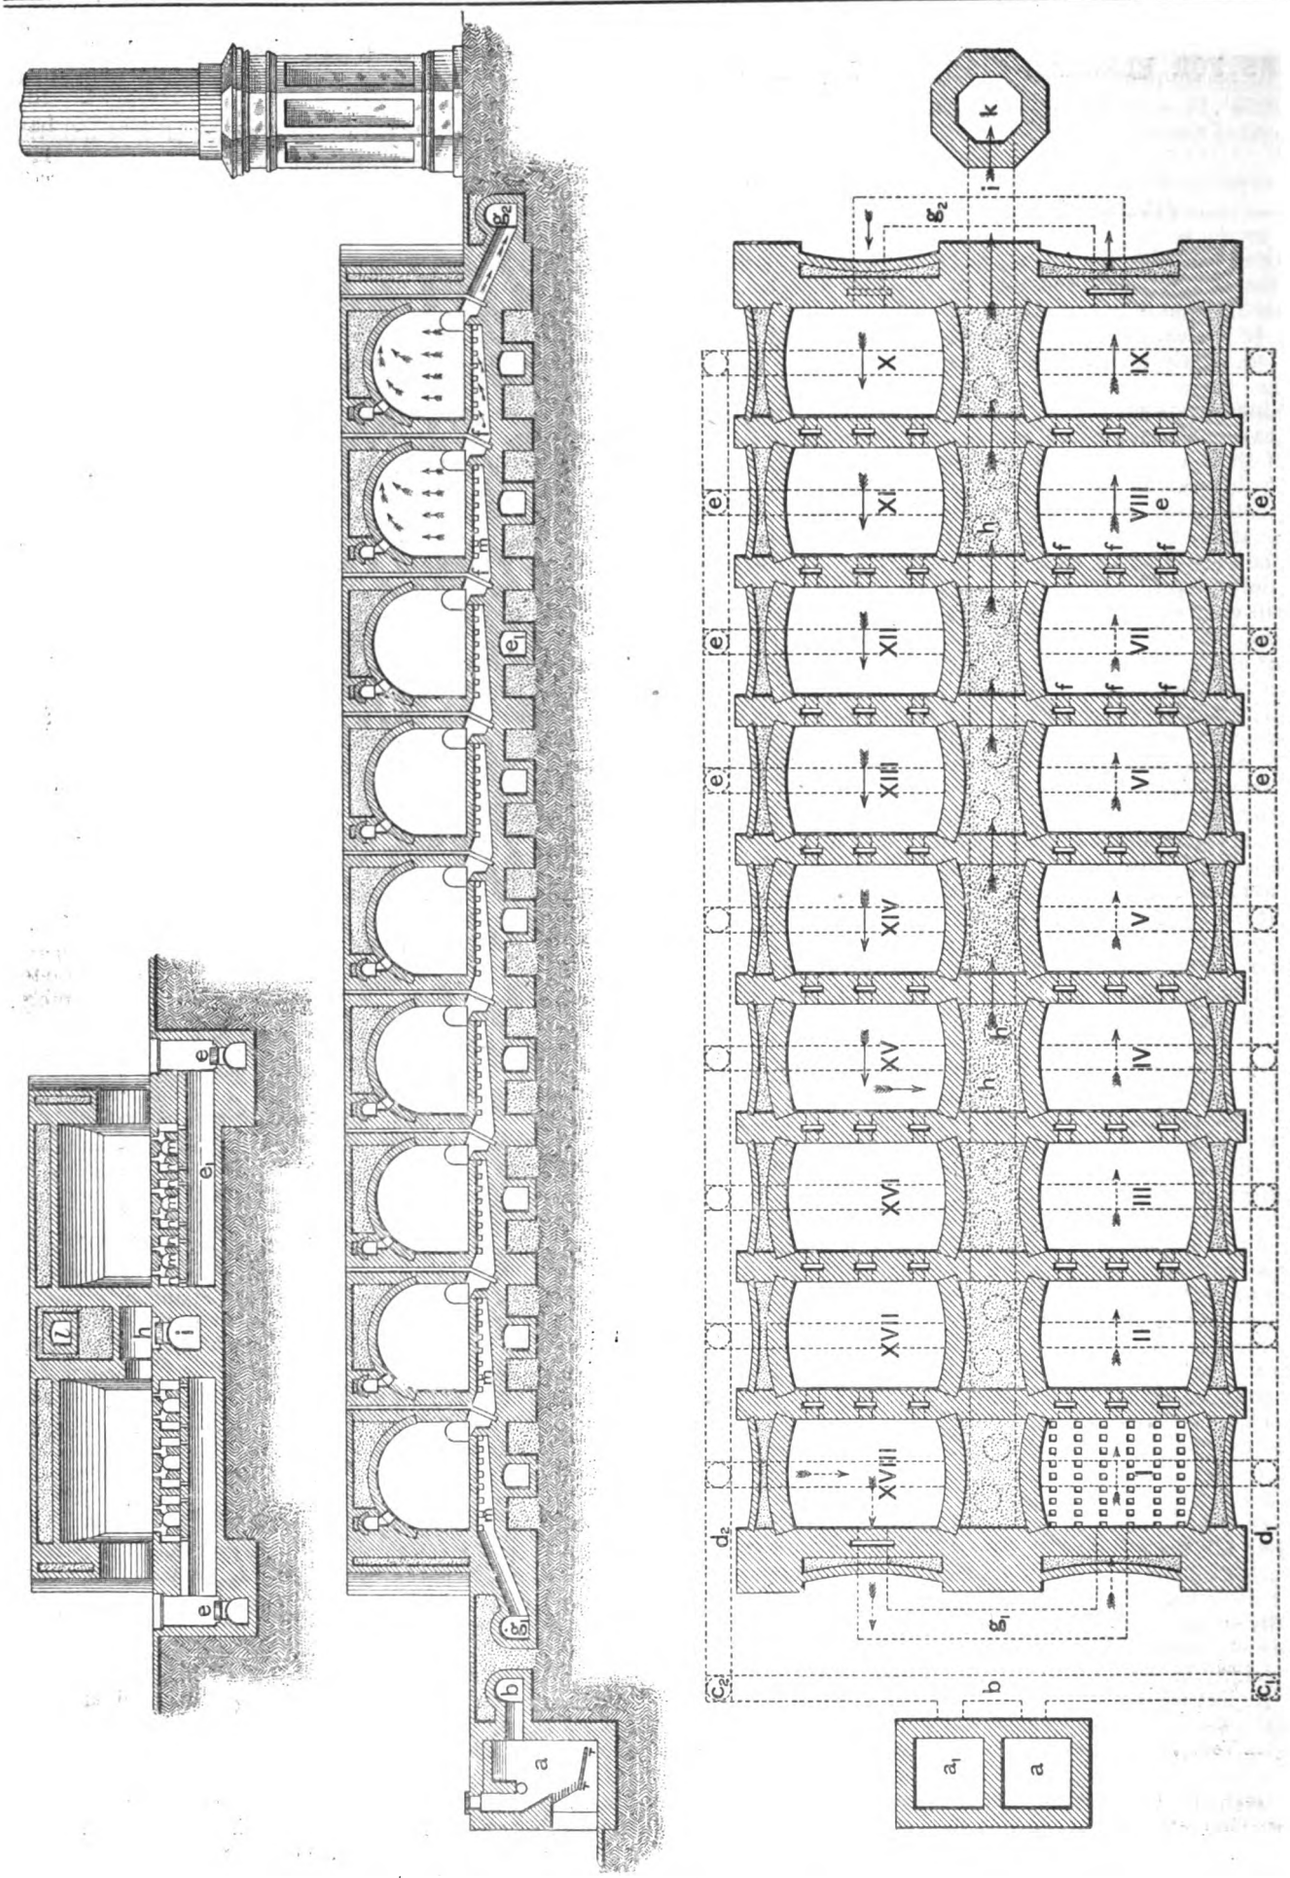

FIGS. 36—38.—Ground Plan, Longitudinal Section and Transverse Section of Mendheim's Chamber Furnace System.

valves *h*, and thus the operation is continued from time to time, there being a constant shifting, as one chamber is finished, to its neighbour, thus working continuously, and obtaining at the same time all the important conditions and requirements that have already been enumerated.

(To be continued.)

LAMP-CONNECTION DIAGRAMS.

The increase in the number of central stations during 1898 is apparent at a glance from the length of the supplement which we issue this week, but an idea of the enormous number of lamps which have been connected to the public supply mains during the year is only obtainable by an addition

m Kensington and Knightsbridge Company.
n London Electric Supply Corporation.
o Notting Hill Company.
r St. Pancras Vestry.
s Westminster Corporation.
u St. James' and Pall Mall Company.
v Metropolitan Company.
w Shoreditch Vestry.

of the items in the corresponding column. As in former years, we have effected this addition for our readers, and show the result in the form of a series of diagrams. Diagram 1 shows the rate of increase of the lamp connections of the London electric supply undertakings. The Metropolitan Company still leads in this respect by a large amount, the smaller increment which we had to record last year having during 1898 been compensated by a very steep rise. The City of London Company's curve still remains above that of the Westminster Company; had it not continued to rise so steeply the dilatoriness of the steam-pipe makers a month ago would not have resulted in such a serious departure from the normal supply pressure. The St. Pancras Vestry curve is now rising steeper than it has ever done before, and the fear that might have

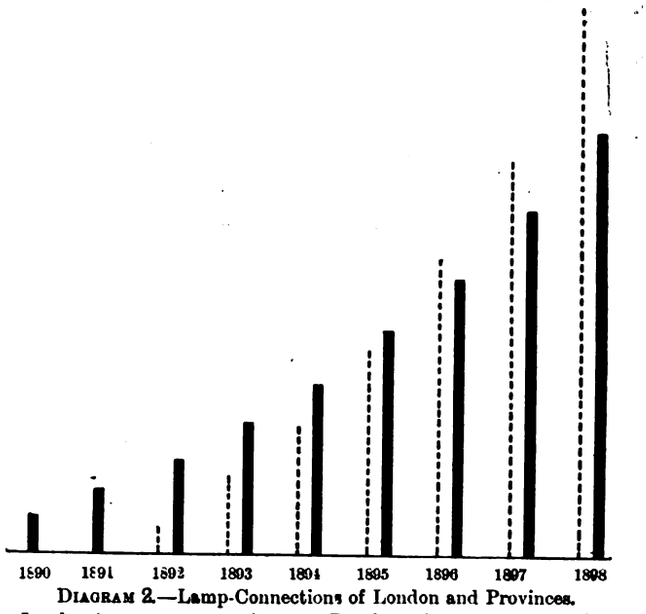

DIAGRAM 2.—Lamp-Connections of London and Provinces.

Scale: 1in. = 1,000,000 lamps.

been entertained last year, that the London Electric Supply Co.'s was approaching a maximum, is set at rest by almost the largest increase in lamp connections that this Company has recorded hitherto. This year the curves of the House-to-House and the Notting Hill Companies bend over considerably, especially the latter.

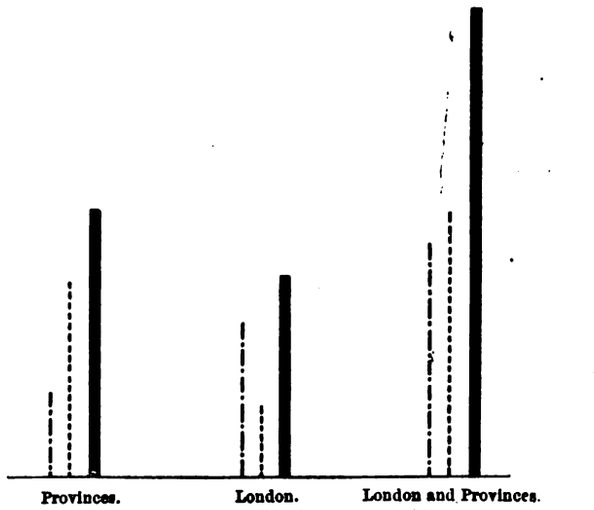

DIAGRAM 3.—Lamp-Connections to Continuous and Alternating Current Stations.
Alternate-Current (— — — — —). Continuous-Current (———).
Alternate and Continuous (— · — · — · —).
Scale: 1in. = 1,000,000 lamps.

The total number of lamp connections in the United Kingdom up to the end of 1898 is 5,206,000 8-c.p. lamps, or their equivalent, an increase of about 1,250,000 over last year, of which, roughly, one-third has been acquired in the metropolis and two-thirds in the provinces. This figure may be compared with the increase of 900,000 during 1897. Diagram 2 shows the steady rise in the total lamp connections in London and the provinces since 1880.

In diagram 3, which shows the relative number of connections to continuous and alternating current stations, the

Digitized by Google

chain-dotted line has increased in length, partly at the expense of the dotted line, owing to a number of alternating stations having put down continuous-current machines for power supply. Thus the City of London Co. is added to the "mixed" stations this year, and in the provinces, Halifax and Salford among others, supply both continuous and alternating currents at present. Diagram 4, showing the relative strength of companies and municipalities in London and the provinces, still shows that the companies have the majority of the lamp connections. As hitherto, this is entirely due to the London companies, while the municipal load in the provinces continues to grow at a great rate. It is apparent that there will soon be as many municipal as company lamp connections in the United Kingdom.

Tables I., II. and III. give the figures used in the diagrams. It may be mentioned that all public supply stations are included in these figures; the lamp connections which have

ELECTRIC LIGHTING NOTICES FOR 1899 SESSION.

The eliminating effect of the £50 cheque which promoters of Provisional Orders are compelled to lodge with the Board of Trade by December 21st has been trifling on this occasion, as only five applications, one metropolitan (for Kensal Town portion of Chelsea) and four provincial (Hythe (Kent), Hythe Sandgate and Cheriton, Romford and Rathmines (Dublin) have been dropped. According to custom, we give below particulars of the 109 remaining applications:—

THE METROPOLIS.

District.	Names of Applicants.
Battersea and Fulham	County of London and Brush Provincial Electric Lighting Co.
Bermondsey	Vestry.
Bermondsey, Rotherhithe, Deptford, Lambeth (portion), Lee and Lewisham	County of London and Brush Provincial Electric Lighting Co.
Bethnal Green	Vestry.
City of London	Charing Cross and Strand Electricity Supply Corporation.
	Metropolitan Electric Supply Co.
City of London, St. Luke (Middlesex) & Holborn	Smithfield Markets Electric Supply Co.
Kensington	Vestry.
Lee	Blackheath and Greenwich District Electric Lighting Co.
Lewisham	District Board of Works.
Plumstead	Vestry.
Stoke Newington, Hackney, St. Matthew, Bethnal Green, Poplar and Whitechapel	County of London and Brush Provinc'al Electric Lighting Co.

THE PROVINCES.

Alloa	Burgh Commissioners.
Arbroath	Corporation.
Ashford	District Council.
Audenshaw	District Council.
Aylesbury	District Council.
Barmouth	Mr. D. Davies.
Barnstaple	Urban Electric Supply Co.
Bexley	District Council.
Bexley, Crayford & Erith	West Kent Electricity Supply Co.
Bognor	District Council.
Bournemouth	Corporation.
Brentford	District Council.
Broadstairs, Birchington and Westgate-on-Sea	Isle of Thanet Light Railways Electric Co.
Buralem	Corporation.
Camborne	Camborne Electricity Supply Co.
Carshalton	Electrical Power Distribution Co.
Castleford	District Council.
Cheltenham	Corporation (extension of area).
Cheriton	District Council.
Christchurch, Pokesdown and Winton.	Bournemouth and Poole Electricity Supply Co.
Clontarf (Dublin)	Township Commissioners.
Cromer	District Council.
Crowborough	Crowborough District Gas Co.
Darfield	District Council.
Dukinfield	District Council.
Dumfries	Corporation.
Durham	Corporation.
East Barnet	District Council.
Eastbourne	Corporation.
East Retford	Corporation.
Erith	District Council.
Failsworth	District Council.
Farnborough	District Council.
Fenton	District Council.
Finchley	District Council.
Gateshead	Electrical Power Distribution Co.
Glossop	Corporation.
Gorton	District Council.
Grays Thurrock	District Council.
Guildford	Guildford Electricity Supply Co.
Halesowen	District Council.
Handsworth	District Council.
Hartlepool	Corporation.
Haslemere, Shottermill, Frensham & Thursley	Mr. E. O. Preston.
Haslingden	Corporation.
Hawick	Urban Electric Supply Co.
Heaton Norris	District Council.
Hendon	Electrical and General Engineering Co.
Heywood	Corporation.
Horsham	District Council.
Ilkeston	Corporation.

District.	Names of Applicants.
Inverness	Corporation.
Keighley	Corporation.
Kilmarnock	Corporation.
Kirkcaldy	Corporation.
Knutsford	District Council.
Leamington	Corporation. / Midland Electric Light and Power Co.
Longton	Corporation.
Ludlow	Corporation.
Lye and Wollescote	District Council.
Lymington	Lymington Electric Light and Power Co.
Maerdy (Ystradyfodwg)	Mardy Electric Light Co.
Mansfield	Corporation.
Merthyr Tydfil	Merthyr Electric Traction and Lighting Co.
Mexborough	District Council.
Mirfield	District Council.
Musselburgh	Drake and Gorham Electric Power and Traction (Pioneer) Syndicate.
Newcastle-under-Lyme	Corporation.
Newport (I. of W.)	Ventnor Electric Light and Power Co.
Newton Abbot	Urban Electric Supply Co.
Partick	Kelvinside Electricity Co.
Pemberton	District Council.
Penzance	Urban Electric Supply Co.
Rawtenstall	Corporation.
Rhyl	District Council.
Rugby	District Council.
Runcorn	District Council.
Ryde	Corporation. / Ryde Electric Light and Power Co.
Sandown and Shanklin	Ventnor Electric Light and Power Co.
Shipley	District Council.
Slough and Datchet	Laing, Wharton and Down.
Stourbridge	District Council.
Sutton Coldfield	Corporation.
Swinton	District Council.
Swinton and Pendlebury	District Council.
Teignmouth	District Council.
Twickenham and Teddington	Twickenham & Teddington Electric Supply Co.
Walker	District Council.
Walton-on-Thames and Weybridge	Electric Works Co.
Wath-upon-Dearne	District Council.
Wednesbury	Corporation.
West Bromwich, Amblecote, Brierley Hill, Handsworth, Perry Barr, Quarry Bank, Smethwick, Kingswinford and Walsall (in Staffordshire), and Dudley, Lye, Wollescote, Oldbury, Stourbridge and Halesowen (in Worcestershire)	Midland Electric Corporation for Power Distribution.
Weston-super-Mare	Weston-super-Mare Electric Light and Power [Syndicate.
Winsford	District Council.
Worksop	District Council.

ELECTRIC TRACTION NOTICES.

Applicants.	Powers sought.
Aberdeen Corporation	To construct tramways, to employ electric traction, &c.
Audenshaw District Council	To construct tramways, to use mechanical traction, &c.
Barking District Council	To construct, work or lease tramways, to adopt electric traction, &c.
British Electric Traction Co.	To construct electric tramways in Birkdale and Southport, &c.
Clayton District Council.	To construct and work tramways, use mechanical traction, &c.
Devonport Corporation	To construct tramways, to adopt electric traction, &c.
Dudley and Wolverhampton Tramways Co.	To equip tramways electrically, &c.
Eccles Corporation	To work tramways, employ electric traction, &c.
Gravesend, Rosherville & Northfleet Tramways Co.	To construct additional tramways, introduce electric traction, to sell undertaking to Drake and Gorham Electric Power & Traction Co., &c.
Ilford District Council.	To construct and work tramways, to employ mechanical traction, &c.
Ilkeston Corporation	To construct and work tramways, adopt mechanical traction, &c.
Ipswich Tramways Co.	To construct additional tramways, to use electric traction, and to sell undertaking to Drake and Gorham Electric Power and Traction Co.
Matlock District Council	To construct and work tramways, use electric traction, &c.
Perth Tramways Co.	To construct tramways, &c.
Queensbury District Council.	To construct and work tramways, to adopt mechanical traction, &c.
Reading Corporation.	To construct and work tramways, use electric traction, &c.
Southport Corporation.	To construct and work tramways, to use electric traction, &c.
Weston-super-Mare Tramways Co.	To construct additional tramways, to use electric traction, &c.
Wrexham Tramways Co.	To construct additional tramways, to employ electric traction, and to sell undertaking to Drake and Gorham Electric Power and Traction Co.

PATENTS EXPIRING IN 1899.

The following is a list of the patents of interest to electrical engineers, which (unless specially extended by recommendation of the Judicial Committee of the Privy Council) will expire during the present year. The list includes only those patents of 1885 which have been kept in operation up to date by the payment of the necessary renewal fees.

Date (1885).	No.	Name of Patentee.	Subject of Patent.
Jan. 13	493	A. Riedler	Valves for pumps, &c.
Jan. 20	819	V. Willis	Improvements in contact-makers
Jan. 21	870	Société Anonyme "Le Ferro Nickel," Paris	Manufacture of metallic alloys.
Jan. 23	999	T. W. Worsdell	Compound steam engines.
Jan. 29	1,275	J. N. Paxman	Improvements in steam boilers.
Jan. 31	1,404	J. I. Thorncroft	Improvements in steam generators.
Mar. 2	2,765	A. Marchenay	Improvements in secondary batteries.
Mar. 2	2,776	W. H. Allen, R. Wright and Gisbert Kapp	Improvements in dynamos and motors.
Mar. 7	3,019	H. S. Maxim	Apparatus for working ordnance.
Mar. 16	3,379	C. Zipernowsky and Max Déri	Improvements in distributing electricity.
Mar. 24	3,813	F. B. Herzog	Electric signalling apparatus.
Mar. 25	3,857	S. Z. de Ferranti	Improvements in electrical switches.
Mar. 26	3,895	J. J. Hood	Manufacture of chromates and bichromates.
Apr. 15	4,071	D. G. Fitz Gerald	Primary and secondary battery plates.
Apr. 27	5,201	C. Zipernowsky, Max Déri and Otto Titus Bláthy.	Improvements in induction apparatus for transforming electric currents.
May 12	5,828	J. J. C. Smith	Vulcanising insulated conductors
May 19	6,110	J. N. Paxman and H. G. Plane	An improved steam boiler.
June 9	6,994	E. H. Cowles and A. H. Cowles	Smelting ores by electric current.
June 24	7,700	Maxime Lahaussois	Improvements in electromagnets.
July 6	8,171	William Buck	Contact-maker operated by passage of train.
July 11	8,416	A. Khotinsky	Electrode frames for secondary batteries.
July 14	8,511	J. Lea & R. Matthews	Signalling on board ship.
July 21	8,811	P. B. Delany	Improvements in synchronous movements and telegraphy.
July 21	8,812	P. B. Delany	Improvements in synchronous multiplex printing telegraphy.
July 21	8,813	P. B. Delany	Improvements in telegraphic apparatus.
Aug. 10	9,527	F. J. Sprague	Improvements in motors for electric railways.
Oct. 22	12,681	J. Brockie & B. Pell.	Improvements in arc lamps.
Nov. 2	13,207	Ed. Martin	Manufacture of wire.
Dec. 8	15,090	G. K. Winter	Railway signalling apparatus.
Dec. 11	15,251	S. Z. de Ferranti	Improved means for distributing electric energy.
Dec. 19	15,639	C. A. Knight (Babcock-Wilcox & Co.)	Improvements in steam boilers.
Dec. 19	15,658	B. M. Drake and J. M. Gorham.	Improvements in electrical switches.
Dec. 29	15,988	W. Elmore and Alex. S. Elmore.	Extraction of metals from their ores.

Map of the County of London.—Builders, architects, wiring contractors and others interested in building operations in the metropolis will welcome the large map of the county of London issued by our contemporary, the *Builder*, as a supplement to the new year's number. The map has been specially prepared from the official map of the London County Council, and corrected up to within a few weeks of publication.

NEW ELECTRICAL JOINT-STOCK COMPANIES OF 1898.

The following are the more important limited liability companies connected with the electrical and allied industries registered during the past year, with their capital:—

	Capital.
Aberdeen Electrical Co.	£10,000
Aron Electricity Meter	250,000
Automatic Light Controlling Co.	10,000
Berrenberg Electric Lamp Syndicate	10,000
Berry's Electrical Co.	3,000
Bersey (W. C.) and Co.	5,000
Bright's Light and Power Co.	200,000
British Columbia Telephones	100,000
British Continental Electricity Co.	20,000
British Electric Meter Co.	5,000
British Electric Transformer Manufacturing Co.	50,000
British Free Electric Light Wiring Syndicate	10,000
British Polyphon Syndicate	10,000
British Schuckert Electrical Co.	200,000
Buenos Ayres and Belgrano Electric Tramways Co	850,000
Bute Electrical Manufacturing Co.	5,000
Camborne Electricity Supply Co.	10,000
Campbell's Patents	15,000
Canadian, British Columbian and Dawson City Telegraph Co.	300,000
Caoutchouc Co.	50,000
Chadburn's (Ship) Telegraph Co.	120,000
Chamberlain and Hookham	100,000
Chilian Electric Tramway and Light Co.	1,050,000
City of Mexico Electric Power Syndicate	5,000
Claud Hamilton	50,000
Clayton Engineering and Electrical Construction Co.	40,000
Clench and Co.	80,000
Cork Electrical Free Wiring Co.	10,000
Costa Rica Electric Light and Traction Co.	130,000
Cowans	30,000
Cowper-Coles Metals Extraction Syndicate	75,000
Crowdus Accumulator Syndicate	50,000
Crystal Electric Lamp and Rose and Bird	50,000
Dargue Acetylene Gas and Electrical Co.	5,000
Davey, Paxman and Co.	250,000
Deep Leads Electric Transmission Co.	20,000
Dennelle and Co.	10,000
Denner (Ernest G.) and Co.	5,000
Direct Telephone Exchange Syndicate	5,000
Doe Portable Electric Light and Power Syndicate	40,000
Douglas Sinclair and Co.	50,000
Doulton and Co.	750,000
Dowsing Radiant Heat Co.	12,000
Drake and Gorham Electric Power and Traction Co.	250,000
Drake & Gorham Electric Power and Traction (Pioneer) Synd.	20,000
Drummond Art Metal Works	5,000
Dutton and Co.	21,000
Edison-Bell Consolidated Phonograph Co.	110,000
Edison Gower-Bell Telephone Co. of Europe	75,000
Electric Installation Co.	100,000
Electric Lamp Supply Co.	10,000
Electric Light and Power Co.	6,000
Electric Lighting and Fittings Corporation	50,000
Electric Power Co. of Santiago de Chili	1,200,000
Electric Railway and Tramway Carriage Works	150,000
Electric Royalties Syndicate	10,000
Electric Supply Co. of Western Australia	100,000
Electric Works Co.	10,000
Electrical Inkless Printing Syndicate	70,000
Electrical Inventions Manufacturing Co.	5,000
Electrical Power Distribution Co.	20,200
Electrical Thawing Syndicate	25,000
Electricity	51,000
Electro-Smelting Co.	10,000
Ellis (H. G.) and Co.	15,000
Engineering Undertakings	5,000
English De Laval Steam Turbine Co.	100,000
Frank Suter and Co.	20,000
Freudenberg's Automatic Telephone Syndicate	10,000
Freudenberg's Multiple Telephone Syndicate	10,000
General Water Power Co.	21,500
Glover (W. T.) and Co.	200,000
Goodman (J.) and Co.	7,000
Hamilton, Motherwell and Wishaw Light Railways Co.	20,000
Hampstead Electric Supply Co.	200,000
Hart Accumulator Co.	40,000
Hart Secondary Battery Syndicate	5,000
Heswall Electric Light Co.	1,500
Highland Water Power Syndicate	20,700
Hiram S. Maxim Electrical Corporation	250,000
Hiram S. Maxim Elec. Light. and Engineering (Pioneer) Synd.	10,000
Hirst (A.) and Son	5,000
Hodges and Todd	25,000
Howell's "Simplex" Anti-Inductive Telephone Syndicate	12,000
Imperial Tramways Co.	300,000
Improved Telephone Patents	300,000
International Lighting Association	100,000
Irish Calcium Carbide Co.	60,000
John Spencer	75,000
Kidderminster and District Electric Lighting and Traction Co.	100,000
La Capital (Extensions) Tramways Co.	100,000
Lancashire Electrical Engineering Co.	5,000
Lancashire Light Railways Co.	50,000
Land and Water Electric Power Syndicate	10,000
Langdon-Davies Electric Motor Co.	70,000
Lloyd and Lloyd	450,000
Love's Electric Traction Co.	20,000

PUBLIC COMPANIES WOUND UP, DISSOLVED &c., IN 1898.

The following are amongst the principal electrical and engineering limited liability companies which have been wound up (either voluntarily or compulsorily) or dissolved during the past year. The asterisk denotes that the company was wound up by order of the Court:—

*Apostoloff Automatic Telephone Parent Syndicate.
*Ariel Arc Lamp Syndicate.
Automatic Electric Sign Co.
Automatic Fog-Signalling and Railway Appliances Syndicate.
B. C. Electric Syndicate.
Bedford Electric Light Co.
British Canadian Development Syndicate.
British Electrozone Corporation.
British Horseless Carriage and Motor Cycle Co.

Digitized by Google

British Hydraulic Jointing Co.
Canterbury Electricity Supply Co.
*Cox Thermo-Electric Co.
Electric and Automatic Engineering Co.
Electric Coal-Cutting Contract Corporation.
Electric Guest Call Co.
Electric Light Regulating Syndicate.
Electric Time Distributing and Clock Co.
Esson Motor.
Globe Electrical Advertising Syndicate.
Harp Arc Lamp Syndicate.
Improved Electro Plating.
J. Goodman and Co.
John Dewhurst and Sons (Sheffield).
John Haynes Lighting Co.
Jones Bros. and Co. (Birmingham).
Knoeferl-Bonn Dental and Electric Manufacturing Co.
London Light Railways Construction Co.
*London-Provincial Electrical Co.
Manchester Suburban Electric Supply. [rators.
National Co. for the Distribution of Electricity by Secondary Gene-
Pioneer Syndicate of the Capital and Counties Electricity Supply Co.
Randall's Phonautograph Co.
Silicon Electric Lamp Syndicate.
Taylor and Tucker Art Metal Co,
Times Electric Lamp Co.
Town and Village Electric Light and Power Co.
United Ordnance and Engineering Co.
West Australian Electrical Trunk Power and Lighting Co.
Western Canada Telephone Co.

The following companies have been voluntarily wound up for purposes of reconstruction :—

British Incandescent Electric Lamp Co.
Carbon Syndicate.
Chamberlain and Hookham.
Coventry Electric Tramways.
Cowper-Coles Zinc Extraction Syndicate.
Crystal Electric Lamp Co. and Rose and Bird.
Dutton & Co.
Great Horseless Carriage Co.
Imperial Tramways Co.
Pearson's Automatic Fire Indicator Co.
Telegraph Manufacturing Co.

CORRESPONDENCE.

DR. LODGE'S SOUND-BOARD TELEPHONE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : In the talking and singing experiment which I showed to the Institution of Electrical Engineers on December 8th, I did not make it clear whether or not I was using any of the magnifying telephones that were on the table in addition to the sound-board telephone. In answer to inquiries, will you allow me to say that I was not. There was no magnification in the case. The speech currents were taken direct round the little coil attached to the deal board and suspended in a magnetic field. And only one such coil was in that instance used. The articulation of a sound-board telephone can be decidedly good as well as loud, and there need be no nasal twang such as is caused by a resonant trumpet or cone.—
Yours, &c., OLIVER J. LODGE.

THE PAST YEAR'S WORK.

We have received a number of reports relating to the past year's work in the electrical industries of a uniformly satisfactory character as to the bulk of orders, and optimistic as to the outlook for the current year. In several cases reference is made, we are glad to find, to a hardening in the prices ruling for heavy machinery. There is no doubt that, in this branch of electrical engineering work, competition has in the past decade been unduly keen and prices unduly cut. The following notes are extracted from reports received :—

Crompton and Co. (Limited).—During 1898 this firm has greatly developed its bare copper main system for electricity supply, the improvements in installation, &c., rendering it suitable for systems of supply at 440 volts across the outers of the three-wire system. Large orders received include the Corporations of Manchester, Edinburgh and Aberdeen, and the companies at Westminster, Harrow, Northampton and Hove. Amongst the municipal undertakings which have been supplied with Crompton plant are West Hartlepool, Canterbury, Stockport, Southampton, York, Gloucester and Wimbledon ; and extension orders have been received from Northampton, Yarmouth and Hove. The light and power works for Calcutta, under equipment by Messrs. Crompton and Co., have during the year made good progress, and it is anticipated that a supply of current will be available in February. The arc lamp department has been very fully occupied, orders having been received from West Hartlepool, Llandudno, Glasgow, Edinburgh, Canterbury, Leith, Lincoln, Islington, St. Pancras, Tunbridge Wells, Aberdeen, Dundee, Southampton, York, Barking, Plymouth, Coventry, Bury, Carlisle, Barrow and Calcutta. The trade in electric motors driven from central supply stations has, the report continues, made rapid progress, and this class of work has kept a considerable portion of the Chelmsford works very fully occupied. The manufacture of electric heating apparatus shows a steady increase, mainly owing, Messrs. Crompton consider, to the fact that this apparatus as now manufactured is very trustworthy. A fruitful cause of failure and annoyance in past years has been the liability of the apparatus to breakdown from accidental overheating by the users, but this liability has now been overcome, with the result that largely increased orders are being placed.

G. E. Belliss and Co. (Limited).—This firm forward a long list of corporations and companies who have been supplied with Belliss patent quick-revolution engines for electric light, power and traction work. The list includes a number of governments and shipping companies, &c., the orders in these cases being the supply of engines for ship and yacht lighting. The illustrations accompanying Messrs. Belliss' report show an installation of six sets supplied to the Charing Cross and Strand Corporation, who have in all 12 sets of these machines in use. Another illustration shows the engines for the Waterloo and City Electric Railway, supplied this year, numbering six 350 B H.P. engines in combination with Siemens dynamos. At the Croydon Corporation Electricity Works there are three 250 and two 350 B.H.P. sets of Belliss engines supplied to the order of the B. T. H. Co. At the Chester station there are 335 B.H P. and two 450 H.P. engines supplied to the order of Messrs. Thomas Parker (Limited). The general report of this firm is that the outlook is satisfactory.

Blackman Ventilating Co. (Limited) —This Company report that business in electric fans and motors is steadily growing, the new enclosed motor type being especially popular. The Company have largely extended their works and are putting down special plant for dealing with the extended demand. It is somewhat remarkable that even larger orders for this useful type of electrical apparatus are not forthcoming, as there is no doubt that, in crowded works and buildings, the electric fan is a great boon, and is, or might be made, an important factor in the day load of many stations. Amongst the contracts carried out by the firm during 1898 may be mentioned the British Museum, the Midland Railway Co.'s hotels, the Bank of England, the Birkbeck Bank, Bankers' Clearing House, the Junior Constitutional, Naval and Military, National Liberal and other clubs, and the offices of the Royal Exchange, Phœnix and other insurance offices, besides a number of well-known hotels and important industrial works in different parts of the country.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

NEW BOOKS AND EDITIONS.

The following New Books and Editions can be obtained of the Booksellers or direct from the Publishing Offices, 1, 2 and 3, Salisbury-court, Fleet-street, London :—

NOW READY.

"ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS."—By J. Elton Young, M.I.E.E. The scope of the book aims at furnishing a fuller treatment of the subject, from the standpoint of the Telegraph Engineer, than it has hitherto received, whilst it endeavours to facilitate a thorough comprehension of the theory of testing as applied to electrical lines in general. The Author hopes that, besides Telegraph and Telephone Engineers, it may, perhaps, also prove of service to those in charge of cables for the transmission of light and power. The localisation of faults has been very fully investigated, including the different degrees in which the various methods are affected by the presence of a second fault or of general leakage.—*Extract from Preface.* Demy 8vo, fully illustrated. 10s. 6d., post free ; abroad 11s.

"SUBMARINE CABLE-LAYING AND REPAIRING."—By H. D. Wilkinson, M.I.E.E., &c., fully illustrated ; price 12s. 6d.

"THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING."—A new work by Messrs. H. K. C. Fisher and J. C. H. Darby, with the above title, is now ready, price 6s. net ; abroad, 6s. 3d. This work is intended to serve as a guide to operators already in the telegraph service, and to those who desire to enter that service. The great cable companies now insist that their operators and probationers shall pass certain examinations in electrical subjects. The book is very fully illustrated. *Second Edition now ready.*

"PRACTICAL NOTES FOR ELECTRICAL STUDENTS."—By Messrs. A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free.

Digitized by Google

"ELECTRO-CHEMISTRY."—By Dr. G. Gore. Third Edition. Price 2s., post free.

"ELECTRIC MOTIVE POWER," by Albion T. Snell, contains the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d., post free; abroad, 11s.

"WIRELESS TELEGRAPHY: SIGNALLING ACROSS SPACE WITHOUT WIRES BY ELECTRIC WAVES."—By Dr. O. J. Lodge, with many original illustrations. *Enlarged Edition*, 2s. 6d. net, 2s. 9d. post free.

"LABORATORY NOTES AND FORMS."—With the above title we have ready the New Edition of a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators and Students. The object of this series is the saving of the time of the Teacher and his Assistants, and to serve as a record of the work done by the Student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen net; in sets of any three, 1s. net; or the set of Twenty (Elementary or Advanced) Exercises can be obtained, price 5s. 6d. net. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. net; or in handy portfolio, price 12s. net; or bound in strong cloth case, price 12s. 6d. net. Strong portfolios can be had, price 1s. each.

NOW READY.—The cheaper edition of Dr. J. A. Fleming's "Electrical Laboratory Notes and Forms." These cheaper Forms have been prepared for the use of students and teachers at the Polytechnic and other science classes throughout the country. The demand for the original set of these Notes and Forms has led to a request for a cheaper set for use at the day and evening classes at many of the technical institutes. These new Forms, which differ only from the higher-priced set in being printed on smaller and cheaper paper and with less space for tabulated records, are issued at half the price of the original set.

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready. Price 7s. 6d.; abroad, 8s.

"THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS."—Edited and enlarged by W. Worby Beaumont. Price 3s. 6d., post free.

"THE ART OF ELECTROLYTIC SEPARATION OF METALS."—A second issue of Dr. Gore's book is now ready, price 10s. 6d., post free.

"THE MANUFACTURE OF ELECTRIC LIGHT CARBONS."—A Practical Guide to the establishment of a Carbon Manufactory. Fully illustrated. price 1s. 6d.; post free, 1s. 9d.

"THE BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH, 1896-97." A valuable, up-to-date compilation. Being an attempt to classify the data relating to X-Ray work. This work contains a quantity of general as well as special information bearing upon the whole subject of electrical discharge research. Price 5s., post free; abroad, 5s. 3d.

"LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS."—By F. C. Raphael. Price 5s., post free; abroad, 5s. 6d. Prospectus on application.

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book, by Messrs. W. Geipel and H. M. Kilgour; price 7s. 6d.; by post, 7s. 9d.; abroad, 8s. A fine large paper edition with wide margins for notes can also be supplied. Price 12s. 6d.; post free, 13s.; abroad, 13s. 6d. *New Edition in the press.*

"THE ALTERNATE CURRENT TRANSFORMER," Vol. I.—By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. *New Edition.* Price 12s. 6d., post free. Vol. II., price 12s. 6d. post free, is also ready.

"ELECTROMAGNETIC THEORY."—By Oliver Heaviside. Vol. I., price 12s. 6d.; post free, 13s.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Flemin, M.A., D.Sc., F.R.S., is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free.

"THE ELECTRICIAN" PRIMERS.—In Two Volumes. Vol. I., Theory. Vol. II., Practice. Price, stout paper cover, 2s. 2d. each, post free; cloth 2s. 9d. Single Primers, 3d. each, post free.

"ARMATURE WINDINGS OF ELECTRIC MACHINES."—By H. F. Parshall and H. M. Hobart. This work has been compiled from notes made by Mr. Parshall in his capacity as Chief Designing Engineer of the Edison and General Electric Companies of America, and is intended to serve as a working treatise on dynamo design. Large 4to, 370 pages, 140 full-page illustrations and 65 full-page tables, 30s., post free.

"DRUM ARMATURES AND COMMUTATORS," by Mr. F. Marten Weymouth, also ready. Price 7s. 6d.; abroad, 8s. Prospectus on application.

"THE POTENTIOMETER AND ITS ADJUNCTS": A Universal System of Electrical Measurement.—By W. C. Fisher. Fully illustrated. Price 6s., post free; abroad, 6s. 6d. Digest post free.

"MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY."—By E. Tremlett Carter, C.E., M.I.E.E. Price 12s. 6d., post free; abroad 13s. 6d. Prospectus post free.

IN THE PRESS.

"THE ELECTRIC ARC."—By Mrs. Ayrton.

"THE MANUFACTURE OF CARBONS FOR ALL ELECTRICAL PURPOSES."—By Francis Jehl.

"ELECTROMAGNETIC THEORY." By Oliver Heaviside. Vol. II.

"SECONDARY BATTERIES, THEIR DESIGN AND MANUFACTURE."—By E. J. Wade.

"PRIMARY BATTERIES: THEIR CONSTRUCTION AND USE."—By W. R Cooper.

"PRACTICAL TELEPHONY."—By Dane Sinclair and F. C. Raphael.

"'THE ELECTRICIAN' WIREMAN'S POCKET-BOOK."

"The Electrician" Electrical Trades' Directory and Handbook.—An important announcement in connection with the 1899 issue of the "Big Blue Book" will be found in an advertisement on another page of the present issue, to which our readers will please refer.

TENDERS INVITED.

The Commissioners of *Govan* invite tenders for the supply and erection of (1) water tube boilers and feed heater; (2) engines and dynamos, equalising transformer, boosters, &c.; (3) lead-covered armoured cables; (4) storage batteries; (5) arc lamps; and (6) arc lamp pillars. Specifications may be obtained from Mr. Arnot, C.E., 79, West Regent-street, Glasgow, and tenders must be delivered to the town clerk (Mr. A. Macdonald), Hillock House, 752, Govan-road, Govan, by 23rd inst. Further particulars are given in an advertisement on another page.

The Corporation of *Lowestoft* invite tenders for the supply and erection of the following plant:—(*a*) boilers and fittings, economisers, feed pumps, &c.; (*b*) pipe work, &c., for engine and boiler house; (*c*) steam dynamos and motor boosters; (*d*) storage batteries; (*e*) main switchboard and connections; (*f*) overhead travelling crane; (*g*) underground mains and conduits, road work, &c.; (*h*) arc lamps and posts; (*i*) station lighting. Plan, &c., may be obtained at the offices of Mr. W. C. C. Hawtayne, consulting engineer, 9, Queen-street-place, London, E.C., after 16th inst. Further particulars are set out in an advertisement elsewhere, and tenders must be addressed to the Town Clerk, at the offices, 115, High-street, Lowestoft, by noon of Feb. 6.

The *Southampton* Corporation invite tenders for the supply of transformers and fittings. Specifications, &c., can be obtained at the office of the town clerk (Mr. George B. Nalder) or at the offices of the engineers (Messrs. Kincaid, Waller and Manville), 29, Great George-street, London, S.W. Further particulars are given in an advertisement, and tenders must be sent to Mr. Nalder, Municipal Offices, Southampton, by 2 p.m. on the 16th inst.

The *Edinburgh* City Council require tenders for the supply of switchboards and boosters for their Macdonald-road electricity station. Tenders to Mr. Thomas Hunter, W.S., City Chambers, Edinburgh, by *Jan. 9, and not Jan. 2* as previously announced.

The *Glasgow* Corporation invite tenders for providing and erecting generating plant at one or other of their new electricity works, including two 200 I.H.P., two 400 I.H.P., three 1,100 I.H.P. and two 2,200 I.H.P. engines, with dynamos and condensing plant. Tenders to town clerk (Sir J. D. Marwick), City Chambers, Glasgow, by *Saturday, Jan. 21.*

The *London* County Council invite tenders for four continuous-current dynamos, one motor generator, two switch-boards with switches, measuring instruments and other work required for the proposed Victoria Embankment electric generating station. Tenders, addressed to Mr. C. J. Stewart, to the County Hall, Spring-gardens, S.W., by 10 a.m., Jan. 31.

The *London* County Council also require tenders for the erection of four gas engines at the proposed Victoria Embankment electric generating station. Tenders to the clerk by 10 a.m., Jan. 31.

The Gas committee of the borough of *Rochdale* require tenders for the erection of electricity station buildings. Tenders to town clerk by Jan. 17.

The *Shanghai* Council invite tenders for a concession, for a period of thirty years, for the exclusive right of establishing and working a telephone system in Shanghai. Particulars of Messrs. J. Pook and Co., 8, Jeffrey's-square, London, E.C. Tenders to Mr. J. O. P. Bland, Shanghai, by noon of March 31.

The *Shanghai* Council also invite tenders for a concession for constructing and working about 23 miles of electric tramways on the trolley system. Particulars from Messrs. John Pook and Co., 8, Jeffrey's-square, London, E.C. Tenders to Mr. J. O. P. Bland by noon of March 15, 1899.

TENDERS RECEIVED AND ACCEPTED.

The *Bolton* Town Council have accepted the following tenders:—Hicks, Hargreaves & Co. for three Lancashire boilers, with accessories, water-feed, blow-off, and drain pipes; Musgrave & Sons for steam exhaust pipes, &c.

The Museum Committee of the *Bristol* Corporation has accepted the tender of Messrs. Mendham and Co. for the extension of the electric light into the curator's department in the Bristol Museum.

The *Leeds* Tramways Committee have accepted the tender of W. T. Henley's Telegraph Works Co. for cables, &c., for the electrical equipment of the Headingley, Chapeltown and Hunslet Tramways, at £8,966. The tender of Messrs. Greenwood and Batley for switchboards, boosters, &c., has also been accepted at £5,330. The Council on Wednesday accepted the tenders of Messrs. G. E. Belliss and Co. for the supply of two 1,000 H.P. engines at £6,150 and £6,000 respectively, and of Messrs. Daniel Adamson and Co. for the supply of four boilers, pipes, &c., at £6,278, and for four superheaters at £648, was also accepted.

The National Electric Free Wiring Co. has secured the Contract for the complete incandescent and arc lighting of the *Preston* Electric Railway and Tramway Carriage Works, Preston. The order

Digitized by Google

for the complete plant and wiring of Messrs. Welch, Margetson and Co.'s premises in Long Lane, Bermondsey, has also been placed with this Company, which is also carrying out the electric lighting of the Cooper School of Art, Canterbury, and the installation of electric motors at Messrs. Lovibond's brewery, Greenwich

The *Stirling* Police Commissioners have provisionally accepted tenders for the erection of the electricity generating station. The total amount of the accepted tenders is slightly over £3,000

The *Belfast* Corporation have accepted the tender of Messrs. Mather and Platt for the supply of four 400 kw. steam dynamos at £14,500.

APPOINTMENTS VACANT AND FILLED.

The Bristol Corporation require a station superintendent for their electricity department. Salary, £175 per annum. Applications to the city electrical engineer (Mr. H. Faraday Proctor), Temple Back, Bristol, by Jan. 10.

The Lighting Committee of the Shrewsbury Corporation require an electrical engineer and manager for their electricity works. Salary £250 per annum. Further particulars are set out in an advertisement elsewhere, and applications must be sent to the town clerk (Mr. H. C. Clarke) by 12th inst.

Two assistant engineers are required at the Hanley electricity works. Applications to Mr. C. A. Cowell, Town Hall, Hanley, by 16th inst.

A stoker mechanic is required by the School Board for London for the training ship "Shaftesbury" off Grays, Essex. Particulars of salary, &c., will be found in an advertisement, and applications have to be sent in to Mr. A. E. Garland, School Board Offices, Victoria Embankment, London, W.C., by noon of Jan. 11.

A competent man, experienced in installation of engines and machinery, to take charge of contract work and to act as resident engineer, is required by the British Thomson-Houston Co. See advertisement.

An engineer, capable of looking after gas engine, dynamos and storage cells, is required for the Manchester Municipal Technical School. Applications to the director (Mr. J. H. Reynolds). See advertisement.

The Electric Lighting Committee of the Portsmouth Corporation are prepared to take pupils with a mechanical training. Particulars from the superintendent (Mr. E. Price), Corporation electricity works, Portsmouth. See advertisement.

Mr. H. M. Harding, of the London Electric Supply Corporation, has been appointed electrician-in-charge at the Hammersmith Vestry electricity works.

Mr. H. W. Miller, who has resigned the position of engineer and manager to the Guernsey Railway Co., has accepted an appointment with the British Thomson-Houston Co.

BUSINESS NOTICE.

Mr. W. R. Cassels has retired from the managing directorship of the River Plate Electric Light and Traction Co. (Limited) and the position will in future be filled by his brother, Mr. Frank Cassels, technical director of the company.

Mr. George W. Webb has been appointed sole London representative for Messrs. H. W. Sambidge and Son, electric light fittings manufacturers, Birmingham.

BANKRUPTCIES, LIQUIDATIONS, &c.

Creditors of the Lamina Accumulator Co. have expressed surprise that no intimation has been made to them of the appointment of a receiver and manager. It is explained that Mr. R. Rabbidge, of 28, Poultry, E.C., the receiver, has been appointed by the Court of Chancery on behalf of debenture holders for between £700 and £800. Mr. Rabbidge expects to get the matter settled directly the Courts open after the present vacation, meanwhile the business is in "temporary suspense." The only hope creditors have of any division of assets in their favour is the sale of the Company's undertakings and patents as a going concern. General creditors will be notified of the result of the action in the Courts as soon as possible.

The creditors of L. V. Riley and Co. met at the Guildhall Tavern, London, on Wednesday, to discuss the proposal made by the debtor for a composition. A letter was read from the solicitors of Messrs. Johnson and Phillips notifying that, as no satisfactory guarantee for the proposed composition was forthcoming, proceedings would at once be taken to issue judgment and execution. The liquidation will, therefore, take the usual course, the debtor filing his petition.

The adjourned petition for the winding-up of the Mannesmann Tube Co. (Limited) will be heard on the 11th inst. in the High Court.

A meeting of the Station Indicator Co. (Limited) will be held at 30, Moorgate-street, E.C., on Feb. 6, to receive an account of the winding-up.

Mr. F. W. Davis, 95 and 97, Finsbury-pavement, London, E.C., has been appointed trustee in the bankruptcy of Thos. King, engineer, St. Peter-street, Maidstone.

Sale by Auction.—Messrs. Fuller, Horsey, Son and Cassell will sell by auction, at the Mart, Tokenhouse-yard, London, E.C., on the 25th inst., at noon, the Bravington Engine Works, Bravington-road, Paddington, London, W.; also the whole of the modern plant and machinery at the Works. The premises are held on lease for 21 years, and are suitable for the business of electrical engineers, scientific instrument makers, &c. Further particulars are set out in an advertisement elsewhere.

Plant for Sale.—Messrs. Furber, Price and Furber announce in our advertisement columns that they will sell at the auction rooms, 77, Chancery-lane, London, W.C., on Tuesday, the 10th inst., at noon, a quantity of electric lighting plant. Catalogues may be obtained from the auctioneers, Warwick-court, Gray's Inn, W.C.

A Caution.—We understand that electrical engineering contractors and engineers generally have recently been given a call by a man soliciting guinea subscriptions for a presentation portrait in oils of Mr. Robert Hammond, and we are informed that the names of a considerable number of firms are shown on the list which the man presents for inspection, it being a condition that an artist's proof shall be given to each subscriber. Not long since the name of Mr. J. W. Swan was used in a similar canvass, and we, therefore, thought it desirable to inquire of Mr. Hammond whether this man has been authorised to collect subscriptions for the object mentioned. Mr. Hammond informs us that he knows nothing of the proposed presentation, and that he has not sat for a portrait in oils. He, however, adds that some time ago he consented to an enlargement being made from a portrait of his by an artist unknown to him, and it is possible that an attempt is being made to sell such enlargements under a bogus "presentation" scheme, just as the attempt was made in the case of Mr. Swan's portrait.

Ambroin.—Messrs. Estler Bros., of 27, Leadenhall-street, London, E.C., forward some particulars of this insulating material, the good qualities of which have led to its adoption by many of the leading electrical manufacturers in this country. It is well known that, on the Continent, ambroin holds an important place in the limited list of really effective insulating materials. Ambroin is composed of fossil copal (which, having been subjected to the action of the atmosphere and water for centuries, no longer contains any substances liable to decay) and silicates. The silicates are thoroughly saturated and mixed with the copal by a patent process so that their capacity for absorbing moisture is entirely destroyed. There is no sulphur or other oxidising substances, and it is weatherproof. After being subjected to pressure, ambroin does not undergo variation in volume, so that the most complicated pieces can be accurately moulded without the necessity of subsequent machining. This is of special importance where the insulation consists of several parts, as all the parts are interchangeable, and the parts particularly subjected to wear are easily replaced. Screws can be moulded in ambroin, which is being largely used for the insulating parts of dynamos, motors and transformers, and also for accumulator boxes, switch bases, resistance plates, fuse boxes, &c.

Battery Hydrometers.—Mr. James J. Hicks, of Hatton Garden, London, E.C., forwards latest particulars of the Hicks patent battery hydrometer, which is now extensively used in the science classes at South Kensington, and by many of the leading scientists. The largest form of this hydrometer has a hooked top, so that it may hang inside the accumulator. It has four differently coloured beads in the tube, indicating different gravities, and the correct gravity is shown on the bead which floats nearest the centre of the tube. A somewhat smaller and cheaper form of the same instrument, loaded with shot at one end, and made to float in the battery, is in extensive use by electric battery makers and supply companies. Other forms are made, all of which, it is claimed, differ materially from other hydrometers and provide an open scale, which renders easy absolutely accurate reading.

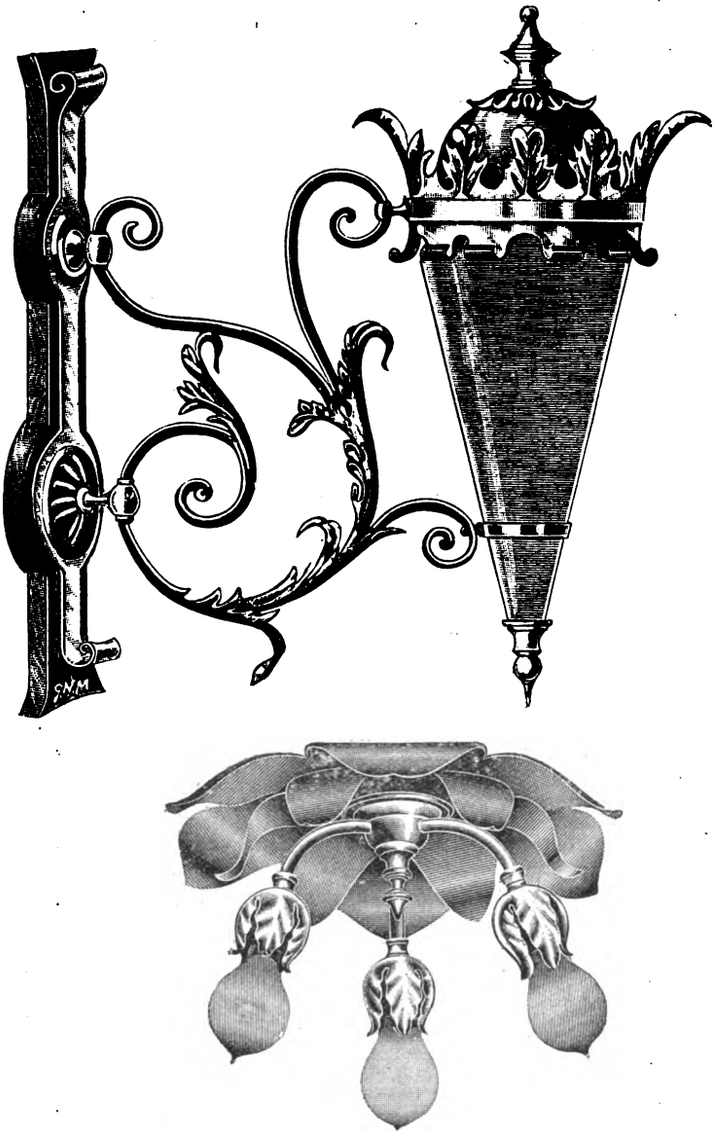
Prepayment Meters.—We have on a previous occasion referred to the merits of the Long-Schattner prepayment meter, and we have to acknowledge receipt of a circular setting out some of the advantages which Messrs. Schattner and Co., of Timberhill, Norwich, claim for this instrument. Copies of the circular can be obtained by the trade on request.

Rawhide Leather, &c.—Mr. S. Schreiber, of 8, Victoria-avenue, London, E.C., who is general European agent for the Chicago Raw Hide Manufacturing Co., forwards particulars of the Company's specialities, which include machine belting, ropes to any thickness for the transmission of power, sewing and lashing laces, packing for hydraulic presses and machines, pinions for noiseless gear, and other important industrial purposes. The particulars received include instructions how to use these goods

Digitized by Google

to the best advantage, and the size and prices at which the articles manufactured by the Company are supplied.

The Ediswan Catalogue.—An advance portion (Section VI.) of the complete Ediswan catalogue is to hand this week, and merits a much more complete review than space at our command will permit us to give. In commenting upon the general excellence of previous sections of this bulky tome we have had occasion to offer a hearty welcome to the conspicuous care and judgment observed in the arrangement of the book. The Ediswan Co., perhaps to a larger extent than any other trading concern in the electrical industry, and by reason of its immense manufacturing and supply business, both home and export, was early in the field with exhaustive publications of this character; and it is, perhaps, for this reason that the company continue to rely mainly upon the wood engraver for illustrations rather than the direct photo process method. It is this latter method, however, that we strongly commend for catalogue work, because, although the wood engraver's



Ediswan Fittings (Catalogue Figs. 3,459 and 3,667).

work is, as is clearly shown by the catalogue under notice, sharper and much more clearly defined, there are many advantages in the absolute facsimile to the actual goods which the photo process method secures. This is very well shown on page 65 of the catalogue. This is the only word of criticism we have to offer upon a work which gives evidence on every page of careful thought and arrangement. There is no crowding; he who runs may read, and the buyer is afforded every help in selecting from one of the largest stocks of electric light fittings of every kind offered by any manufacturing firm in the world. The catalogue opens with a commanding list of agents who handle the company's goods in all parts of the globe, and while the Ediswan Company in this way keeps its well-known manufactures and its even better-known name prominently before the world's buyers, it need have no fear of competition, however keen—and we fully recognise that in this particular branch competition is keen. The catalogue has a smart appearance and is tastily printed, and from every point of view is a credit to the officials responsible for its production. There are a hundred illustrations worthy of inclusion in this notice, but it must suffice if we show two examples which strike us as being particularly good specimens of the metal workers' art, as well as being typical of very useful and ornamental classes of electric light fittings.

The Edison and Swan Co. have recently laid down further special plant to enable them to cope with the increasing demand for the new type F instruments, recently introduced. The company are holding large stocks of all standard ranges. Voltmeters in six different ranges between 20 and 160 volts and ammeters in five different ranges between 4 and 110 amperes are stocked at low prices.

British Goods for Far Eastern Markets.—We have received from the "Eastern Press" (Limited), of 3, Chancery-lane, London, E.C., a copy of the current issue of the Japanese and English *Journal of Commerce*. This journal was established in 1892 in the light of suggestions repeatedly made by consuls abroad that English manufacturers should appeal to Far Eastern buyers in their own language. The journal is printed throughout in Japanese, and is a very creditable production. The contents include a number of articles of industrial interest, mainly in relation to the world's trade generally and in its relation to Eastern markets particularly. From the same publishers we have received a copy of the *Chinese Journal*, prepared on similar lines and also produced in London, and which circulates throughout China. Both publications are issued quarterly, and serve a very useful purpose.

Calendars, &c.—Messrs. W. H. Willcox and Co. issue a large quantity of circulars and stationery in connection with their well-known engineers' stores and general supplies, and amongst several of these just to hand is a useful pad calendar, upon each sheet of which is illustrated a number of the firm's specialities.—Messrs. Hodges and Todd, Limited, forward a neat and useful hanging month-by-month calendar for 1899.—Messrs. Croggon and Co., Limited, have sent a handy-sized office calendar, illustrating a number of their special manufactures.—From Messrs. J. H. Holmes and Co. comes a calendar blotting pad.

The "Engineering Magazine."—The January issue of this magazine contains articles on "The Relations of the United States to their New Dependencies," by Capt. T. A. Mahan; "The Engineer and the Policy of Imperialism," by C. B. Going; "The Fighting Engineers at Santiago," by A. Warren; "Machine Shop Management in Europe and America," by H. F. L. Orcutt; "Equipment, Management and Economic Influence of the Ship Canal," by W. H. Hunter; "The Building of Oxford, from an Engineer's Point of View," by J. W. Parry; "Machinery and Power Applications in the Lumber Industry," by Wm. Adams; "The Evolution of Safety in Railway Travel," by Ch. Hansel; "Mining the Iron Ores of Arctic Europe," by D. A. Louis; and "The Commercial Aspect of Electric Lighting in Great Britain," by Robert Hammond. The Review of the World's Engineering Press is also given. Copies of this number can be obtained at the offices of *The Electrician*, 1, 2 and 3, Salisbury-court, Fleet-street, London, E.C.

"Cassier's Magazine."—The January number of this magazine contains articles on "The Electric Motor for Small Industrial Purposes," by Alfred H. Gibbings; "Block-Setting Titan Cranes," "An Early Locomotive," "Aristotle and Modern Engineering," "Subaqueous Rock Excavation without Explosives," "The Valve Gear of the Willans Engine," "How the Pyramids were Erected," "Engine-Room Experience in War Time," and "American Locomotive Repair Shops."

Exports of Electrical Apparatus and Material.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from Dec. 29 to Jan. 3, with the ports of destination:—

Argentina—Rosario, £621 (including £60 telegraph material). *Australasia*—Adelaide, £1,593 (telegraph material); Melbourne, £25; Port Pirie, £15; Sydney, £170; Wellington, £80. *Ceylon*—Colombo, £89. *Columbia (Republic of)*—Santos, £12. *Egypt*—Alexandria, £17. *France*—Bordeaux, £17. *Germany*—Hamburg, £118 (including £110 telegraph material. *Holland*—Amsterdam, £30. *India*—Bombay, £24; Calcutta, £108; Madras, £32. *Italy*—Spezia, £548. *Japan*—Yokohama, £320. *Malta*—£97. *Norway*—Christiania, £617 (including £444 telegraph material). *South Africa*—Cape Town, £58; Durban, £2,569 (including £2,405 telegraph material); Port Elizabeth, £135. *Spain*—Barcelona, £10. *Straits Settlements*—Singapore, £252 (telegraph material). *Uruguay*—Monte Video, £536. *West Indies*—Trinidad, £70. Total (for six days) £8,163, against £107,375 (and 3,000lb. telegraph cable) for eleven days last year (Dec. 25 to Jan. 4).

Digitized by Google

MUNICIPAL, FOREIGN AND GENERAL NOTES.

Aldershot.—The District Council will consider at its next sitting a report from the Electric Lighting committee recommending that steps be taken for the erection of electricity supply works in the district. The estimated cost of an electricity station capable of supplying current to the equivalent of 6,000 8 c.p. lamps is put at £11,000 by the engineer, Mr. Nelson Dennis.

American Pacific Cable Schemes.—Mr. Corliss, of Michigan, has introduced into the House of Representatives a bill to secure the laying, under Government control, of cables connecting the mainland of the United States with Hawaii, the Philippines, Japan and China. Under the bill the President is authorised to cause the cables to be laid, and the House is asked to appropriate a sum sufficient to provide for cables of a minimum efficiency of 15 words per minute. The cable, when completed, is, under the terms of the bill, to be handed over to the United States Post Office Department for working as part of the postal service. A tariff not exceeding $1 per word is fixed for private messages, and a sinking fund is to be formed by receipts from the cable service beyond cost of operation. In connection with his bill Mr. Corliss calls attention to the fact that the concession obtained by Mr. Scrymser for landing rights for the Pacific cable at Hawaii gives the Pacific Cable Co. exclusive landing rights for 20 years. A bill is now before both Houses of the United States Legislature to provide for grants being made in aid of the Pacific Cable Co.'s scheme of $100,000 per year for 20 years. Dated Dec. 31, Reuter states that Secretary Hay, at the instance of the Hawaiian Commission, has formally expressed his disapproval of the rights secured by the Pacific Cable Co. as above-mentioned.

Brierley Hill.—The District Council will oppose the application of the Midland Electric Corporation for power distribution.

Bucharest.—A Belgian syndicate has purchased the tramways of this city for 17,500,000 francs (about £600,000). It is proposed to equip the lines on the overhead trolley system, and also to supply current for lighting.

Bury St. Edmund's.—The Local Government Board have sanctioned the Town Council's modified electric lighting scheme. The amount proposed to be borrowed is between £15,000 and £16,000.

Colwyn Bay.—Messrs. Lacey, Clirehugh and Sillar have been instructed by the District Council to prepare a scheme which will provide for both public and private electric lighting in this district. Hitherto the Council have adopted only a small scheme for lighting the promenade.

Crewe.—A Local Government Board inquiry has been held to inquire as to the application of the Town Council to borrow £26,000 for electric lighting purposes. Mr. F. Cooke, the town clerk, said that the Corporation had secured a site for a generating station which the consulting engineer (Mr. B. Hopkinson) considers an extremely good and central one. The estimated capital expenditure entailed by the scheme is £24,198. There was practically no opposition.

Derby.—The borough electrical engineer (Mr. T. P. Wilmshurst) has presented a report on the extension of the electricity buildings and the provision of additional machinery at the station to meet increasing demands. The estimated cost of the extensions, including structural alterations, is £25,000. The Electric Lighting committee have endorsed Mr. Wilmshurst's recommendations, and advise the Council to apply for sanction to borrow the money. The proposals were approved by the Council on Wednesday.

Dewsbury.—Owing to the Town Council having decided to construct a system of electric tramways, the scheme of the British Electric Traction Co. is to be opposed.

Disclaimer.—We are requested to state that Major Hector Tulloch, C.B., retired R.E., and lately chief engineering inspector of the Local Government Board, is not the person who was a Director of the West Australian Trading Syndicate, two of the Directors of which are under prosecution by the Public Prosecutor.

Dorking.—The Council are about to appoint a consulting engineer for their electricity scheme, and Messrs. W. C. C. Hawtayne, W. H. Trentham and J. S. Raworth have been invited to attend before the Electric Lighting committee.

Dublin.—Mr. M. Ruddle, the electrical superintendent, has been granted a bonus of £50 for extra work owing to the recent failure of the electric light cables. The Corporation have decided to apply to the Local Government Board for a supplementary loan of £7,000. The estimated cost of renewing the cables and mains, which was originally put at £22,000, is now found to be at least £26,000.

Dudley.—The Council on Tuesday appointed Mr. R. P. Wilson consulting electrical engineer, when it was decided to obtain tenders for electric generating plant. The Railway, Tramway and Electric Lighting committee have been authorised to borrow £7,500 for the erection of a station.

Dundee.—The Town Council have decided to extend the electricity generating station to accommodate plant for tramway purposes. The whole of the extensions are estimated to cost about £15,500.

Garston.—The District council propose to transfer their provisional order to the British Insulated Wire Company, who offer to establish electricity works in the district, and to supply current for private lighting at 5d., and for public lighting at 3d. per unit. The company also undertake to erect, in conjunction with the electricity works, a refuse destructor, and to burn refuse at 9d. per ton. The council reserve right to purchase. The matter is to be discussed at the next meeting of the council.

Gateshead.—The Town Council, on Wednesday, adopted the agreement with the Electrical Power Distribution Co. as to the terms, &c., upon which the latter are to supply electric current in the district.

Glasgow.—As the result of a further conference between the representatives of the Kelvinside Electricity Co., and the subcommittee of the Glasgow Corporation as to the purchase of the company's undertaking, the city electrical engineer (Mr. W. A. Chamen) has been instructed to draw up a fresh report. It will be remembered that the company offer to sell at £50,000. and the Corporation offer £30,000.

In a report prepared by the tramway manager (Mr. John Young), it is stated that the overhead system has been in operation for over ten weeks. A full service has been given for a portion of the time, and the horse cars altogether withdrawn. For the first few weeks, when the number of electric cars was small, and the service novel, the receipts per car mile were abnormally high. The drawings for the whole period from October 13 to December 24 averaged 16·01d. per car mile. Taking the last five weeks, during which they might safely assume the receipts had reached their normal, the average had been 14·88d. per car mile. For the corresponding five weeks of last year the receipts from the horse cars was 11 per mile, but the average for the route throughout the period from Jan. 1, 1897, to Oct. 8, 1898, was 12·24d. per car mile. Taking the larger figure for the horse cars, the electric cars show an increased revenue of 2·46 per car mile. It was rather soon to give a definite figure as to working expenses under electric traction, as the condensing plant had not yet been in operation; but after including a fair sum for maintenance and renewals, it might be taken that the total working expenses would not exceed 6½d. per car mile. The average working expenses under horse traction might be taken at 6½d. per car mile, although during the last financial year the amount worked out at slightly under that figure. This shows a saving in working expenses for electric over horse traction of at least 2d. per car mile. There was no doubt that even with the small power station at Springburn, were all the available power utilised, as it would be when the route to Govanhill was opened, a still larger saving would be effected. The result, so far, had been an increased revenue of 2·64d. and a decreased expenditure of 2d. per car mile, being a total gain of 4·64d. This gain on the present mileage on the Springburn route (2·40 miles of double track) would amount to £10,000 per annum.

The Clyde Navigation Trustees have decided to adopt electric lighting. At first the installation will be confined to the large open spaces where night work is conducted. The Trustees have decided to purchase the current required for the north side; and current for the south side will be provided by an independent installation. The supply and erection of the lamps, &c., and the laying down of the installation will be let by tender.

In the report by the city engineer on the ventilation of the City Chambers, it is recommended that electric fans be introduced.

Gothenburg (Germany).—In March, 1897, a committee was appointed to collect information, &c., bearing upon electric tramways in relation to the projected electric lines to be established in Gothenburg. This committee has now reported recommending the erection and equipment of an electric power station and electric tramways on the overhead system, the track to be leased by the existing tramways company, and the lease to be for 20 years after the lines are completed. At the expiration of this period the city will work the line after paying to the company the value of the rolling stock. The Gothenburg Tramways Co. (which now uses horses) has been granted a concession up to 1917, and the present proposal is intended to be a compromise between the municipality and the company. Two other persons have asked for concessions to build electric tramways, but have been refused. Messrs. Siemens and Halske, of Berlin, have furnished an estimate giving the total cost of construction (value of sites for the buildings not counted and value of the old tramways deducted) at about £100,000, of which the city's share would be £68,500, which includes cost of the power plant (£19,300). The yearly working expenses are put at £16,000. The proposed contract provides that the company will pay yearly to the city 8 per cent. of the cost of construction of the track, &c. (power plant excluded), £8,500. If the gross receipts of the com-

Digitized by Google

pany in any one year exceed £21,500 the company pays the city 12 per cent. of the excess. The city reserves the right to arrange workmen's trams before eight o'clock in the morning, and stipulates that passengers who have paid regular fare on one tramway line may continue on another by paying half fare in addition to the sum first paid. The work is to begin in May, 1899, and two of the lines must be finished before November, 1899, and the remainder opened for traffic by September, 1900. The railways will have a length of 13,347 yards, of which 13,041 yards is double track.

Hampton.—The surveyor (Mr. J. Kemp) has prepared a report for the District Council, and recommends the erection of electricity supply works. The cost of an installation, capable of supplying current to about 5,000 8 c.p. lamps, is put at £14,000, and after allowing for sinking fund and interest a net annual profit of about £120 is shown.

Hereford.—The Town Council recently received 17 tenders for the supply and erection of electric lighting plant. As the cost of the generating plant and mains will amount to about £12,000 application is to be made to the Local Government Board for sanction to borrow £20,000 for carrying out the scheme. The proposal to utilise water power has been abandoned.

Ilfracombe.—The District Council have decided to engage a consulting engineer to advise them upon electric lighting matters, and more particularly as to whether the Council should engage in the business of electricity supply.

Leeds.—The newly appointed Electric Lighting committee presented their first report on Wednesday, and recommended that an expenditure of £16,409 be authorised to carry out extensions of sub-stations, and to lay mains to the Hunslet district at a cost of £8,408. The committee are desirous of supplying current to Hunslet, where a large number of big engineering works are established. The committee's proposals were adopted by the City Council.

The Tramways sub-committee have decided to proceed with the electrical equipment of the Beckett-street and York-road sections of the tramways. It is hoped that these lines will be in operation electrically by July or August next.

Leith.—The Council anticipate being able to supply electric current to private consumers next week.

Manchester.—The Electricity committee have been requested by the Council to report as to the steps they are taking for providing the necessary electrical equipment and power to enable the Tramways committee to commence working the tramway system of the city and suburbs by electricity in 1901; and also as to the advantages and disadvantages of supplying current for the tramways at a pressure of 400 volts.

Oswestry.—The Oswestry Electric Lighting Company have offered to light the whole of the district by incandescent electric lamps at £3 per lamp per annum. The proposal is at present under consideration by the council. The company further offer to erect and supply current, free of cost, for one month for four 1000 c.p. arcs, after which, if the lamps are required, current will be supplied at 2d. per unit.

Paris.—The electric light has been introduced into the Chamber of Deputies, Paris, under the direction of the commission presided over by M. E. E. N. Mascart. There are 4,610 lamps in all, 1,440 in the various parliamentary services outside the Chamber, 2,640 in the Hotel de la President and the Grand Saloon, and 530 in the anterooms. The Chamber is not yet lighted, as a new and much finer room is in course of construction. Gas engines are employed to drive the dynamos, and a battery of Tudor accumulators is also installed.

Postal Telegraph Clerks and their Grievances.—A petition is, it is stated, to be presented to Parliament setting forth the grievances under which the postal telegraph clerks of the country are alleged to suffer. The question of wages, compensation for partial abolition of classification, insufficiency of salary increments, and other questions are to be placed before Parliament. The petition asks that a select committee be appointed to consider the whole question of the present and future position of the operatives.

Redditch.—The District Council have entered into an agreement with the National Electric Free Wiring Co. for the wiring of premises in the district on "easy" terms. A loan of £10,911 at 2¾ per cent., repayable in 25 years, has been taken up by the Council for electric lighting purposes.

Sheffield.—The undertaking of the Sheffield Electric Light and Power Co. was formally taken over by the Corporation on Saturday, when a cheque for £260,000 was handed to the chairman of the company (Alderman Franklin).

Southport.—The Town Council have taken up a loan of £21,178 for electric lighting purposes.

Southport-Lythom Electric Tramway.—The Preston Town Council have decided to oppose the bill for the construction of this line.

Teddington.—As a result of a conference with a committee of the Twickenham District council, the Teddington council are recommended to make early application for a provisional order. This decision is due to an application lodged by Edmundson's Electricity Corporation.

Telegraph to Klondyke.—A Reuter's telegram from Winnipeg announces that a statement is published that the Federal Government contemplate the construction of telegraph lines and a wagon road from Ashcroft to Dawson City, a distance of 1,400 miles. The line, it is said, is to take the road cut out more than 30 years ago when a scheme was on foot for reaching Europe by telegraph through Siberia.

Telephone Trunk Extensions.—Cirencester, St. Austell, Truro and Penzance are now on the telephone trunk line system of the country.

Tunbridge Wells.—The Town Council decided on Wednesday to borrow a further £25,000 for electric lighting extensions.

Twickenham.—The District Council are recommended by the Lighting committee to apply for a provisional order, and to take steps to oppose the application of Edmundson's Electricity Corporation.

Warrington.—The Town Council have before them a report from the Electric Lighting committee recommending the erection of electricity supply works. The Council's consulting engineer (Mr. A. H. Preece) advises the adoption of the low-tension continuous-current three-wire system of distribution with a pressure of 440 volts between the outers. The total cost of the scheme, exclusive of buildings, is £30,000.

Whitfield (Glossop).—The District Council have created a special committee to consider the erection of electricity works and the construction of tramways.

York.—The City Council have arranged with the National Telephone Co. for placing the telephone wires underground.

Dinner.—The head office staff of the National Electric Free Wiring Company dined together at the Holborn Restaurant on the 30th ult. The chair was taken by the manager (Mr. B. H. Jenkinson).

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by Mr. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom all information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete Specifications. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

November 27, 1898.

24,965. G. T. HANCHETT and F. B. SAGE, Manchester. A new or improved electrical resistance measuring instrument.*

24,982. W. R. SMITH. London. Improvements in appliances for overhead electric traction.

25,009. C. VERNIER. London. A new or improved electric arc lamp.

25,013. A. VOSMAER. London. Improvements in or connected with electric arc lighting.

25,023. O. BRENNECKE and I. TIMAR. London. Method of heating electrically propelled tramway cars and other vehicles.*

November 28, 1898.

25,051. C. A. GILLESPIE. Glasgow. Improvements in or relating to combined pressure or vacuum registers and electric alarms.

25,058. H. G. SOLOMON. London. The spring automatic fuse replacer for electrical cut-outs.*

25,098. S. P. THOMPSON. Liverpool. Improvements in electric surface contact tramways.

25,109. J. W. BROWN and A. J. G. SIMPSON. London. Improvements in electric hoisting machinery.

November 29, 1898.

25,202. L. SCHOTT. London. Improvements in electric alarm clocks.

25,217. R. ECHTERMEYER. London. Improvements in and relating to the production of electric currents.*

25,221. J. J. RATHBONE. London. Improvements in electric arc lamps.

November 30, 1898.

25,259. K. OBST. Liverpool. Improvements in electrical revolution indicators.*

COMPANIES' MEETINGS AND REPORTS.

United River Plate Telephone Company (Limited).

A general meeting of this Company was held on Tuesday, under the presidency of Mr. J. IRVING COURTENAY.

The SECRETARY (Mr. Robt. Herring) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, the object of this meeting is to place before the shareholders the position of the Company at the expiration of the first six months of its current financial year. It has been thought desirable by the Directors that such a statement should hereafter be given at about this time. The shareholders are widely scattered, and the place where our business is carried on is so far from most of them that if the information directly emanating from the Board is made public only once a year they are not likely to be as well informed as they ought to be as to how the business stands, and what its immediate prospects are. For several years things were in such an unsettled state in Argentina that it was difficult to say with any certainty how matters would turn out, and, consequently, your Board has felt it necessary to be most conservative in their action and guarded in their statements, and to allow what they thought to be ample margins for contingencies, with the result that the Company has actually been stronger and its prospects brighter than would appear from the mere facts and figures set forth in the reports from time to time. We now hope and believe that our future is more settled. While we cannot expect perfectly smooth sailing, for this is not in the nature of a telephone business, we may with confidence look forward to fair progress and to a sound business, which, though not free from the fluctuations that are incidental to this class of business generally, may with reason be considered as certain and safe in its results as any such business can be. With the field in the River Plate constantly widening, with the increasing demands in every direction for telephone services, with improvements in telephones, switchboards, cables, and plant, you can understand that the business is of magnitude, and that it requires constant thought and attention in dealing with it, in order that it should adequately serve its purpose and maintain a satisfactory position before the public and the shareholders. The results in our case give, we think, ample indications that the business has been attended to with care and judgment, and the Directors have been most gratified to find at the annual meetings that the shareholders have appreciated the work that has been done as well as the results that have been obtained. One of our local Directors, Mr. Adolph Fels, is present with us to-day, and he fully agrees in this view. During the half-year just elapsed there has been an all-round improvement, an increase in subscribers and the like in revenue, while the outlook justifies an anticipation of a continuance of this satisfactory condition of things. But it must be noted that the expenses in the River Plate will be increased this year chiefly on account of the fall in the gold premium, which increases the sterling value of all salaries, wages and other expenses payable in Argentine currency. Our manager (Mr. Chappell) assures us that he has steadily persevered in his endeavours to keep down expenses to the lowest possible point, and to keep our plant, &c., in the highest state of efficiency. It may be thought that a large part of the expenses incurred for such improvements could without impropriety be charged to capital expenditure, but, in the judgment of the Directors, the course pursued by this Company, in charging these outlays to revenue, is the correct one for a telephone company to follow, the right theory being that a telephone subscriber is entitled to the best service that can be given, and that the plant, as a part of the working expenses, should be so kept up, renewed and renovated, at whatever cost may be necessary, as to ensure such a service. It is with this idea that we are proceeding towards a complete renovation of our central system in Buenos Aires, to be followed, we anticipate, with similar procedure in Rosario and also with the sub-offices in both districts, and in the meantime we hope with a perfected telephone connection between the two cities. All of this work, of course, means a good deal more than the up-keep of existing plant; it means large capital expenditure as well, but expenditure that will be spread over a considerable period; and we do not doubt that as needed it will be possible to obtain the requisite funds. For the present we have before us the completion of our new building in Buenos Aires, the erection of the new switchboard with an immediate capacity for over 4,000 subscribers, and an underground plant with metallic circuits for the same. This latter work is partly done. In regard to the Provincial Telephone Company of the Province of Buenos Aires, in which we have a large interest, steady progress can be reported. It will take time to properly cover the various districts, but the important points are gradually being occupied by the Provincial Company, and we are naturally affording them every assistance. The financial position of our Company is stronger now than ever before, the gold premium notwithstanding. In anticipation of expenditure upon our Central Office building and otherwise, as stated in my remarks at the general meeting in July, there has been a further issue of the Five per Cent. Debenture Stock, and £28,000 has been allotted. The balance of £20,000 is not required at present—probably it may be in another six months or so. The subject of an interim dividend is one to which the Board has given attention. In view of the large expenditure before us, we do not feel it prudent, as yet, to make such recommendation In closing my remarks, I wish to mention that our Managing Director, Mr. F. W. Jones, shortly leaves for the River Plate to go over the districts where the operations of the Company are carried on, and inspect the work he has had so much to do with ever since the telephone became known in that country. There is no resolution to be proposed, and no accounts to be presented, and if there are no questions to be asked, that will conclude the business of the meeting.

Mr. STOBART and Mr. LEA SMITH, having referred to the passing of the interim dividend, the latter shareholder asking if the debentures would be offered *pro rata* to the shareholders,

The CHAIRMAN said they could not say at that time what the amount of expenditure would be. He did not think it wise to increase the capital account; he thought it better in prosperous times, when they were getting a fair dividend, to devote part of their revenue to capital purposes. When half-yearly meetings were advocated he felt that the shareholders would at the same time like to have an interim dividend, but this was a point which was delicately avoided at the last meeting. The question was before the Board, and they would like to pay an interim dividend, but in view of the large expenditure to which he had referred, they did not think it prudent to announce an interim dividend. The debentures would be offered *pro rata* to the shareholders.

A vote of thanks to the Chairman and Directors terminated the proceedings.

NEW COMPANIES, STATUTORY RETURNS, &c.

ELECTRIC RESISTANCE AND HEATING CO. (LIMITED).—This company was registered on Dec. 31 with a capital of £120,000 in £1 shares, to acquire certain inventions in relation to the manufacture of electrical resistance material, and of any existing or future patents (except for Austria and the Balkan States), and to carry on the business of electricians, electrical, mechanical and general engineers, suppliers of electricity, electrical apparatus manufacturers, fitters, wire drawers, metal workers, &c. The first subscribers are: A. Conder, J. T. Clary, W. Chaplin, T. G. Fort, W. Andrew, F. W. White and G. F. Honig.

CHATHAM, ROCHESTER AND DISTRICT ELECTRIC LIGHTING CO. (LIMITED).—The annual return to March 31 was filed on Dec. 23. The nominal capital is £50,000 in £5 shares, of which 1,863 are considered as fully paid, and the full amount has been called on the remainder.

CONNOLLY BROTHERS (LIMITED).—The annual return to Dec. 1 has been filed. The nominal capital is £20,000 in £5 shares, of which 2,360 have been taken up. 1,793 shares have been issued as fully paid, and the full amount has been called on the others.

HALIFAX AND BERMUDAS CABLE CO. (LIMITED).—The annual return to Dec. 28 gives the capital as £50,000 in £5 shares, of which the whole has been taken up, and all the shares have been issued as fully paid.

CITY NOTES.

MEMORANDA.—Bank rate 4 per cent. (since Oct. 13, 1898). Price of silver 27¼d. per oz. (Jan. 5). Consols (2¾ per cent.) 110⅛—110⅝ for money, 110¾—110⅞ for account; 2½ per cent. 103⅝—104¼ (Jan. 5). Stock Exchange Settling Days: Stocks and Shares Continuation Days, Jan. 11 and 25; Ticket Days, Jan. 12 and 26; Pay Days, Jan. 13 and 27; Mining Share Carry over Days, Jan. 10 and 24.

CHARING CROSS AND STRAND ELECTRICITY SUPPLY CORPORATION (LIMITED).—The coupons on the Five per Cent. Debentures (Nos. 1 to 100), due on 1st inst., will be paid on 2nd prox. at the Charing Cross branch of the Union Bank of London.

CITY OF LONDON ELECTRIC LIGHTING CO. (LIMITED).—Warrants for the interest due on the £400,000 Five per Cent. Debenture stock have been posted.

CROMPTON AND CO. (LIMITED)—The directors of this company have declared an interim dividend at the rate of 5 per cent. per annum for the half-year ended Sept. 30 last.

DOULTON AND CO. (LIMITED).—The whole of the letters of allotment of the Five per Cent. Preference shares of this company have now been

Digitized by Google

posted. The work of allotment has been very heavy, the customers of the firm alone having applied for the whole issue many times over.

NEW YORK LIGHTING TRUST.—A company, entitled the New York Gas and Electric Light, Heat and Power Co., has recently been formed in New York for the purpose of securing control of the electric light, heat and power undertakings of New York City. Its capital is $25,000,000, and its leading spirit W. C. Whitney, prominently identified with the Metropolitan Street Railway Company of New York, which owns many miles of conduits, and a power house having a capacity of 70,000 h.p. The Mount Morris Electric Company, the Manhattan and the Edison Electric Illuminating Company have already been acquired, and the only company not acquired is the Westinghouse Electric Company. It is stated that the control of the electric facilities by the new concern is absolute.

SALISBURY ELECTRIC LIGHT AND SUPPLY CO. (LIMITED).—The third ordinary general meeting of this company was held last week at Salisbury. The directors reported that under their contract Edmundson's Electricity Corporation (Limited) had laid mains in the principal streets of the city, and constructed an electric lighting station complete with turbines and all machinery and appliances for the generation by water and steam power and distribution of a supply of electric current, and under their management supply was commenced on June 22 last; one month's free lighting being offered to persons who should have their premises wired by that date. The equivalent of 962 8-c.p. lamps connected to the company's mains at the commencement of lighting had now considerably increased. Ample space for additional plant, when required, had been reserved. Payment for these works would be made under the contract by an allotment of fully paid shares and 5 per cent. debentures. No further share capital beyond the 3,807 shares already issued could be offered to the public without the sanction of the contractors, who had also the option of subscribing at par for any further capital which the company might find it necessary to issue. The contractors had agreed to complete the remainder of the works and hand over the whole undertaking as a going concern on January 1. The Chairman moved the adoption of the report, and congratulated the shareholders upon the progress made. There was a specific item as to the issue of shares under the contract with Messrs. Edmundson. They had insisted, and rightly insisted, that when the company wanted to raise any more money they were to have the first right to take the shares. This tended to increase the value of the shares, for the reason that Messrs. Edmundson would have to pay par for the shares instead of their having to sell them to raise money, or to offer more debentures. They would not therefore have to appeal to the public of Salisbury again. There were connected on the 31st Oct. 1,527 lamps. Since that they had had 276 more, and up to the 17th of Dec. 221 extra, making in all 2,024 lamps actually connected. There were 207 in process of being connected, so that very shortly there would be 2,231 lights in use amongst 60 consumers. They could very reasonably look forward to a very large increase from private supply in the city. The report was adopted.

SHEFFIELD ELECTRIC LIGHT AND POWER CO. (LIMITED).—An extraordinary meeting was held on Wednesday to authorise the winding up of the company consequent upon the purchase of its undertaking by the Sheffield Corporation. The undertaking was formally handed over to the city on Saturday last. On handing over their share certificates shareholders will receive a payment at the rate of £17. 10s. per share. The balance in hand will probably amount to 8s. or 9s. per share. The resolution to wind up was unanimously carried, and Messrs. Franklin and Gamble were appointed liquidators.

SIEMENS AND HALSKE AKTIEN GESELLSCHAFT.—An extraordinary meeting has been called for Jan. 12 to authorise the increase of the capital from 40,000,000 to 45,000,000 marks (£2,000,000 to £2,250,000). The capital was increased in March last from 35,000,000 to 40,000,000 marks.

WESTERN UNION TELEGRAPH CO.—This Company have issued their report for the quarter ended Dec. 31. The following statement exhibits the condition of the Company at the close of the quarter ended Sept. 30, 1898:—

Surplus July 1, 1898, as per last quarterly report......		$7,963,235 12
Net revenues, quarter ended Sept. 30, 1898		1,527,236 79
		$9,490,471 91
From which deducting for—		
Dividend of 1¼ per cent. paid Oct. 15th	$1,216,985 00	
Interest on bonded debt	224,272 92	
		$1,441,257 92
Left a surplus Oct. 1, 1898, of..................................		$8,049,213 99
The net revenues of the quarter ending December 31, based upon nearly completed returns for October, partial returns for November, and estimating the business for December, were about		1,450,000 00
		$9,499,213 99
From which appropriating for— Interest on bonds		224,273 00
		$9,274,940 99
It requires for a dividend of 1¼ per cent. on capital stock issued, about		1,216,985 00
Deducting which leaves a surplus, after paying dividend, of		$8,057,955 99

In view of the preceding statements, the Committee recommend that a dividend of 1¼ per cent. on the capital stock of the Company be declared payable on and after the 16th inst.

NOTES.

A POST OFFICE circular, dated 6th inst., announces that the POSTMASTER-GENERAL, with the consent of the TREASURY, has decided that the practice of requiring bonds from established officers holding Civil Service certificates shall be discontinued. This decision is in conformity with a recommendation of the TWEEDMOUTH Commission, and will relieve a large section of telegraphists who are employed at public counters from an irrational and vexatious impost. In the opinion of the Commission, the pension to which established Civil Servants are entitled is itself sufficient security, if not against fraud, against pecuniary loss to the Crown, all claim to pension being forfeited by misconduct. It now only remains for the Guarantee Society, which has been run more for the personal benefit of a few official shareholders than in the true interests of the service, to promptly wind itself up, and restore their money to the aggrieved bondholders.

THE summary of Mr. PREECE'S work in connection with induction telegraphy, recently brought before the Institution of Electrical Engineers, will be welcomed by everyone interested in the subject. But Mr. PREECE is either badly informed or unduly modest in his statement in the first paragraph of his Paper, for we think more attention has been paid to his work than he supposes. He has presented yearly reports on the subject to Section A of the British Association, and, in many instances, it is true, these have not been made public property, yet all those to which he himself appears to attach the greatest importance have appeared in the columns of *The Electrician*—in fact, we find that a great portion of the text of his present Paper is the same as his British Association Paper, read at Oxford in 1894. In our reprint of the former, in another part of this issue, we have added footnotes to indicate where accounts of the majority of the experiments referred to may be found, and we trust that this will facilitate reference and comparison, and enable the reader to gain a fair idea of the magnitude and importance of Mr. PREECE'S experiments on an extensive scale in induction telegraphy.

THE most efficient thickness for transformer sheet iron is a matter of considerable importance to electric supply undertakings that are wedded to alternate currents. Messrs. F. BEDELL, R. M. KLEIN and T. P. THOMPSON have brought out a short monograph on the subject, which is practically a reprint of a Paper read by them last year at the Boston meeting of the American Association for the Advancement of Science. The authors find that there is a wide working range for the best thickness of plate, say from 10 to 15 mils, which, for practical purposes, will be sufficiently near the absolute best, for any ordinary range of induction, frequency and thickness of insulation. This result has been arrived at, not by direct experiment with different thicknesses, but by means of a graphical investigation of STEINMETZ'S equations for hysteresis loss and eddy current loss. It will be seen, then, that the validity of the conclusion entirely depends upon the applicability of the equations over the range of thicknesses investigated, a matter which is open to considerable doubt.

A RECENT issue of the *Electrical World*, of New York, describes a telephone cable patented by Mr. S. D. FIELD, in which strands of soft iron wire are laid between the insulated conducting wires. In his specification, Mr. FIELD says that he has found experimentally that this insertion of iron wire produces beneficial effects. The idea is by no means new, however, Mr. OLIVER HEAVISIDE in many of his Papers having considered the effects of iron on telephone circuits, both when forming part of the conductors, when combined with the insulator, and when exterior to both. Perhaps his clearest discussion of the question, or at any rate that which will appeal most to the "practician," is in Vol. I., § 218, of his "Electromagnetic Theory," in which "Various Ways, good and bad, of increasing the Inductance of Circuits" are considered without mathematics and from a practical point of view. The employment of iron wires in a similar way to Mr. FIELD'S is mentioned, and it is pointed out that what is really wanted is iron subdivided in planes perpendicular and not parallel to the conducting wires. It is doubtful whether

Digitized by Google

in Mr. FIELD's pattern the large increase in capacity caused by the introduction of the iron wires will not quite counterbalance the advantage of increased inductance. The cable may, perhaps, have advantages for single-wire circuits, for, just as in the Tatham cable, in which strands of tinsel, connected to the lead sheathing, were laid between the insulated wires, the effect of external electrical disturbances will be diminished.

ON the 17th inst. an important American telephone patent will expire, one which has had a very great influence on the telephone industry in the United States. The patent in question is the Firman multiple switchboard patent, covering broadly all types of multiple exchange switchboards. The claim is as follows:—"The combination of two or more switchboards at the central office of a telephone exchange system, to each of which the same telephone lines are connected, whereby any two of these lines may be connected together upon either of the multiple switchboards." This patent has been the property of the American Bell Telephone Co., and, in consequence, all of the "independent" telephone concerns have been obliged to make use of more or less clumsy transfer arrangements as soon as their number of subscribers has exceeded a few hundred. We have commented on these in our editorial columns on a previous occasion. Although the expiry of this patent allows independent companies more latitude in the design of their switchboards, many types will still remain for some time the exclusive property of the Bell Company. The multiple system with series or "break" jacks will be free, but the patent for the "branching system," in which the jacks of the multiples are in parallel instead of in series, remains valid both in this country and in the United States. In both cases it is the property of the Western Electric Co., who manufacture in America solely for the Bell Co. Nor will the independent companies be able to employ the "engaged test" used by the Bell Co. (and also by the National Telephone Co. in this country) as that is also still covered by a patent in the United States. We may, therefore, look forward with interest to hearing what our inventive cousins will devise as a substitute for this test, for, in spite of the advocacy of transfer systems and the be-littling of the importance of multiple switching on the part of those who were unable to use the latter, we may safely anticipate that several of the American independent telephone companies will now be converted to more modern methods.

A CURIOUS problem of a minor order has arisen in connection with the proposed electric tramways at Southampton. Antiquarians are justly proud of the historic Bargate, which stands in one of the principal streets; but the structure as it now stands is as a stumbling-block to those who wish to use the overhead trolley system for the tramcars that pass under the quaint old gateway. It is manifestly impossible to run the trolley wires through the arch as it is at present constructed, but the proposed alteration of the structure has raised a great outcry among the townsfolk. An alternative proposal is to lay down a few yards of conduit under the archway, thus leaving the Bargate absolutely untouched. Considering that this would involve a double equipment for every car, one for the trolley and one for the microscopic length of conduit; and taking also into consideration the two halts which conversion from the one system to the other and back again would necessitate, this seems somewhat a heroic expedient. Would it not be simpler to station a horse or two at the Bargate?

THROUGHOUT the United Kingdom and, indeed, in all parts of the world where electric supply is available, a variety of rules and regulations are in force, relating to such matters as free-wiring, hiring out motors, &c., systems of charging for current, &c. These regulations are so numerous and varied in character that we now earnestly invite officials of electrical undertakings to forward to us copies of their regulations, in order that a systematic comparison between them may be made in our columns. We have already made such comparisons from time to time, and are assured of their utility to the electrical profession; but in order that the most up-to-date and complete information may be embodied, it is necessary for us to be supplied promptly with the official regulations; and we hope that, in the interests of the profession, this will be done.

Cable Interruptions.—

	Date of Interruption.
Para—Maranham	Nov. 15, 1898

Long-Distance Telephone Line in Japan.—According to the *Engineer*, a telephone line has been opened between Tokyo and Osaka, a distance of 356 miles.

Lectures on Dynamo and Transformer Construction.—Mr. James Swinburne commenced yesterday a course of lectures upon "Dynamo and Transformer Construction," at the Electrical Standardising, Testing and Training Institution, Faraday House.

Telegraph Operators in Cuba.—It is stated that the United States war department is experiencing difficulty in obtaining efficient telegraph operators for the military lines in Cuba. A large number of operators were enlisted in the Volunteer Signal Corps, but these were in most cases released from regular positions on the understanding that they might resume them at the end of the war. A great many have, therefore, returned to the telegraph companies, and, in consequence, the military authorities are short of men. The war department has about 300 miles of telegraph line under its control, and it is expected that many more lines in the island will be transferred to the American government.

American Calcium Carbide Regulations.—Steps have been taken in New York to control the trade in calcium carbide, and regulations have been issued governing the transportation, storage and sale of the product, which firemen declare to be the source of danger in a burning building. The regulations require that hereafter, in transit or in storage, calcium carbide must be enclosed in hermetically sealed iron receptacles marked "Dangerous, if not kept dry." No package may contain more than 100lbs. The carbide must be stored in isolated buildings that are fireproof and waterproof, and no artificial light or heat will be permitted in the building where it is stored. The manufacture, transportation, storage, sale and use of liquefied acetylene is absolutely prohibited within the limits of the city. The regulations were framed by the Bureau of Combustibles, and the Fire Department has ordered their enforcement.

Personal.—The Postal and Telegraph staff of the Metropolitan Northern District have presented to their late Postmaster, Mr. James Laister, M.I.E.E., a gratifying testimonial on his retirement, consisting of a massive and beautifully-fitted walnut writing table and chair. The telegraph messengers, on their own account, added a handsome hall clock. The presentation took place in the Barford Saloon, Agricultural Hall, Islington, where a large number of postal and

Digitized by Google

telegraph officers assembled, on Saturday evening last. Mr. Laister commenced his career as a boy telegraph clerk with the Electric and International Telegraph Co. as far back as 1851.

We learn that, without any request on his part, the salary of Mr. Steinitz, the borough electrical engineer at West Ham, has been increased by £200 per annum, an example which might well be copied by some other municipal bodies.

It is announced that Sir Spencer Walpole, K.C.B., permanent secretary to the Post Office, retires from that position to-morrow (Saturday) having completed his sixtieth year. He became permanent secretary in 1893.

Converse of the Zeeman Effect.—Prof. G. F. FitzGerald writes to *Nature* as follows:—

I have not seen it noticed that a converse action to the Zeeman effect should exist. A radiating atom in a magnetic field gives out circularly polarised light. A circularly polarised beam of light should cause a directed rotation of the electrons, so that the absorbing gas should be magnetised and exhibit magnetic force. If all the molecules in a cubic centimetre of gas were caused to rotate their electrons in the same direction, it would possess quite a considerable magnetic moment. It is very improbable that the action of a circularly polarised beam of light would control the motions to such an extent as that; but it is quite possible that, if a circularly polarised beam of sunlight were passed through a strongly absorbing gas, it would magnetise it to an observable extent. The same effect would probably exist in any medium in which absorption was principally due to syntony and not mostly due to viscous actions. Hence I would expect some effect with absorbing substances like fuchsine. It is doubtful whether lampblack, iron, or other metals have a sufficiently syntonous absorption to exhibit the effect. My assistant, Mr. Thrift, is engaged in trying the experiment, but in the meanwhile I thought it might be of general interest to point out that such an effect should exist.

Telegraph and Telephone, 1898.—Extensions of British Trunk Telephone wires during the past year were as follows:—In January extensions took place to Banbury, Banff, Elgin, Inverness, Peterhead, Rugby and Ware; in February to Pentre (South Wales), Spennymoor, Cromer, Buckie and Newmarket; in April to Coldstream; in May to Weybridge; in June to Hereford and Bradford-on-Avon; in July to Cowbridge; in August to Wexford, Waterford and Market Harborough; in December to Dunoon, Rothesay and Nairn. Various extensions and improvements relating to land and submarine telegraphs abroad have taken place. A reduction was made in the rates to British Guiana, as well as to Mexico and certain of the West India Islands. An alternative route has been provided to Jamaica by means of a new cable from Bermuda, *via* Turk's Island. In the British and French possessions on the West Coast of Africa, and in the Italian possessions on the East Coast, a number of additional telegraph stations have been opened. Lastly, the capture of Khartoum has been promptly followed by the establishment of telegraphic communication with that city.

An "Electric Pony."—A small 550-watt locomotive, mounted on a single wheel, and used for drawing a small two-wheeled chaise is described under the above title in a recent number of the *Énergie Électrique*. The motor is geared to the wheel by means of a train of spur wheels, and the same wheel is used for steering, a handle, resembling in appearance that of a bath chair, being fixed to it. The motor weighs some 65lbs., and drives the wheel at 9½ miles an hour. The locomotive wheel carries a tray, in which are 15 to 20 Fulmen cells, each weighing 15½lbs., and having a capacity of 80 to 85 ampere hours at a normal discharge rate of 20 amperes. The chaise can run 30 to 45 miles without recharging. The motor is series wound, and the speed is regulated by a rheostat, there being four positions for forward motion. In the fourth position the rheostat is short-circuited, and the field shunted by a resistance. There are also two backward speeds, and an intermediate position of the controller handle short-circuiting the motor. The controller is placed under the seat of the carriage, the handle being at the side. There are two pedal brakes, one being merely a switch to interrupt the current, and the other a band-brake. The weight of the carriage is about 1½cwt., that of the "pony" about 4cwt. MM. Mildé are the manufacturers of this miniature automobile.

"Electric Gas Lighting."—A writer in the *Electrical Engineer*, of New York, states that an experimental electrical laboratory recently visited by him had Bunsen burners of the ordinary kind for heating small articles, and that these were lit without the aid of matches. Over the bench, located so as to be within easy reach of the gas burner, is fixed a copper brush, made of the frayed ends of incandescent lamp cord. This brush was connected to one side of a 110 volt circuit in series with a large magnet, wound with fine wire, and consequently having high self-induction. The Bunsen burner was connected to the other side of the 110 volt circuit by a wire running inside the rubber tube, connecting it to the gas-cock. Before reaching the gas-pipe, however, a short length of metal pipe was inserted in the rubber tube, and connection was made to this to avoid grounding the circuit on the gas-pipe. To light the burner, gas is turned on, and the tip of the burner is simply touched to the brush and drawn away again. The circuit is closed as soon as the burner touches the brush. When the burner is taken away a flash ensues, because of the high self-induction of the circuit, and the gas is lit. The method, as installed there, is entirely safe, and eliminates whatever fire risk may be connected with matches as well as saving time and making it more of an inducement to turn out the gas when it is not wanted.

The Municipal Electrical Association.—We have received a copy of the *Proceedings* of this Association for 1898. It includes a full reprint of the Papers read at last year's Annual Convention in London, and of the discussions which followed them. From the Secretary's report it appears that the number of municipal electricity committees elected to membership of the Association during the year 1897-8 had been 14, increasing the total number to 55. Seventeen electrical engineers had been elected and five had retired, the total being 63, and the number of assistant engineers who were Associates of the Association had increased from 45 to 54. The approval of the sub-committee to the "Standard Clauses for Specifications," drawn up by representatives of the Electrical Engineering Plant Manufacturers' Association and the Municipal Electrical Association (see *The Electrician*, Vol. XL., p. 662), was endorsed at the General Meeting, and the clauses are reprinted in the volume of the *Proceedings* before us. It is to be regretted, however, that Mr. R. P. Sellon's name should have been printed as Salon. A scheme for the creation of a benevolent fund, brought forward by Mr. Wordingham, has met with the approval of the Council and Members of the Association. It is hoped that those who are willing to contribute to it will send their remittances to the Secretary, Mr. A. B. Mountain. With a view to encouraging the reading of Papers by Associates, the Council has decided to offer a prize of five guineas for the best Associate's Paper presented, and we may mention that for the present the Council have generously decided to subscribe the necessary amount among themselves, so as not to burden the funds of the Association. It is also announced that the Council has arranged to keep a record of any plant corporations may have for disposal, and corporations wishing to buy or sell second-hand plant are requested to communicated with the Secretary.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-day) FRIDAY, January 13th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Students' Meeting, when Dr. Archibald Barr will deliver an address on "The Application of the Science of Mechanics to Engineering Practice."

TUESDAY, January 17th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Papers to be read with a view to discussion: (1) "The Effects of Wear Upon Steel Rails," by W. G. Kirkaldy; (2) "On the Microphotography of Steel Rails," by Sir William C. Roberts-Austen, F.R.S.

WEDNESDAY, January 18th.

INSTITUTION OF ELECTRICAL ENGINEERS.

7:30 p.m. Students' Meeting in the Library of the Institution. Paper to be read: "The Effect of Governors on the Parallel Running of Steam Alternators," by L. Wilson.

ROYAL MICROSCOPICAL SOCIETY.

8 p.m. Ordinary Meeting at 20, Hanover-square.

THURSDAY, January 19th.

INSTITUTION OF CIVIL ENGINEERS.

2:30 p.m. Students' visit to the Testing and Experimental Works of Messrs. David Kirkaldy & Son, 99, Southwark-street, S.E.

Digitized by Google

CONTEMPORARY ELECTRICAL SCIENCE.

[Compiled by E. E. Fournier d'Albe.]

Properties of Reflected Cathode Rays.—Previous to 1881 it was generally believed that cathode rays came to an end when they encountered a solid obstacle. In that year, however, Goldstein discovered evidences of the reflection of cathode rays. Recently (*see* Vol. XLI., p. 848) Starke has measured the reflective powers of various metals for cathode rays, and found them to vary roughly with their densities. Ernest Merritt has made an interesting test to find whether the velocity of the cathode ray particles is sensibly altered by reflection at an anticathode. The latter was perforated, so that some of the cathode rays proceeded to the other end of the tube, while another portion was reflected at right angles into a side tube. The direct and reflected rays could thus be examined under identical conditions as regards potential and exhaustion. The experiments agreed in showing no difference in the deflection of the direct and reflected rays by the same magnetic field; hence the velocity of the particles is not sensibly changed by reflection. Since the cathode particles are able to pass through metallic films it cannot be the target, as a whole, which reflects them; hence it must be the metallic molecules themselves, and their unchanged velocity is a valuable confirmation of the view that they must be very small in comparison with the molecules. They rebound as rubber balls would rebound from a heavy projectile.

[Merritt, *Phys. Review*, Nov., 1898.]

Electrothermal Relations.—In a Paper covering 72 pages of *Wiedemann's Annalen*, E. Riecke works out a mathematical theory of the relations between thermal and electric phenomena, based, not upon Maxwell's system, but upon the conceptions underlying Weber's theory, which, as he points out, still holds the field in electrolytic theories and all theories involving ions of the liquid state. Several efforts have been made to reduce metallic conduction to an electrolytic phenomenon. Riecke boldly assumes the identity of the particles involved in thermal and electric conduction, and, after a few pages bristling with symbols, he arrives at such equations as

$$\frac{g_p}{g_n} = \frac{\mu_p c^2{}_p u}{\mu_n c^2{}_n v},$$

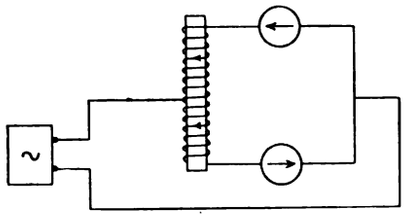
where g is the "specific rate of displacement by heat," μ the mass of a particle, c a constant characteristic of the particle (the suffixes denoting the positive or negative sign), and u and v the speed of the positive and negative ions wandering with the current. The thermo-electric and thermo-magnetic effects are dealt with in detail in a manner which requires careful study to fully appreciate, and eventually the author enters upon new ground by transferring his conceptions from metallic conductors to vacuum tubes. The Paper at this point becomes distinctly exciting: The movable negative particles are the same for all metals; the ratio e/m being assumed as 512×10^{15}, the constant c_n becomes a velocity of $4{\cdot}02 \times 10^5$. Cathode ray particles are the negative particles responsible for part of the thermal and electric conduction in metals. Canal rays are positive particles which turn out to be the metallic ions themselves, and $c_p = 6{\cdot}90 \times 10^3$cm. sec.$^{-1}$. Zeeman's particles are negative ions moving in circular orbits of radius $0{\cdot}021 \times 10^{-6}$mm. The author even calculates the diameter of Ampère's molecular currents. The whole Paper is either a magnificent extension of our boundaries of knowledge or a terrible waste of time.

[Riecke, *Wied. Ann.*, Nos. 11 and 12, 1898.]

Electric Cohesion.—T. Tommasina has observed a peculiar phenomenon of adhesion or cohesion under the influence of the electric current, which may serve to elucidate some obscure points in the properties of coherers. He was engaged in experiments with an elementary coherer in the shape of a simple pendulum with a bob of nickel-plated brass resting lightly on a pinch of nickel filings, supported by a horizontal copper plate. The coherer was inserted in a circuit operating a relay, which lighted a small lamp when the current passed. The author found that when the copper plate was lowered the connection between the pendulum and the nickel filings was not immediately broken, but was maintained by a mobile and flexible little chain of filings, sometimes as long as 2cm. Only one such chain was formed at a time. While it lasted it continued to keep the lamp burning. On cutting off the current the chain collapsed in a short time. Filings of several metals were tried, and it was found that the chains were readily formed by the noble metals, but not by iron, magnesium, antimony and bismuth. The author does not attempt an explanation, but if the phenomenon is due to electrostatic attraction, it is evident that the contact between the particles must be very intimate indeed, and this is more likely to be the case in noble metals than in others.

[Tommasina, *Comptes Rendus*, Dec. 12, 1898.]

Chemical Rectification.—The rectification of alternating currents by means of electrolytic cells containing aluminium electrodes facing carbon or lead electrodes was first proposed by Graetz and Pollack. A similarly unsymmetrical action was obtained by Eichberg and Kallir in the case of a metal-carbon arc, and by Nichols in a spark-gap between a point and a sphere. L. Kallir discusses the theoretical aspects of the "aluminium valve" on the supposition that the current in one direction is completely stopped, while for the other direction each cell has a definite ohmic resistance. He traces a current curve for a single valve, which is intermittent and approximately sinusoidal. He proposes a new arrangement for a non-intermittent current, as illustrated by the annexed diagram, in which the arrows indicate the direction of the transmitted current. The author shows that if the inductance



in the circuit is large in comparison with the resistance, the current is nearly uniform. There is no throttling. Only one half of the magnetising circuit shown is, of course, traversed at each alternation, but that does not signify when only external effects are to be created. The arrangement shown could be used for the self-exciting of alternate-current generators.

[Kallir, *Zeitschr. für Electrotechnik*, Dec. 18, 1898].

Condensation Nuclei.—The study of the condensation of water vapour on nuclei produced by various agencies has lately been called in to furnish evidence concerning the nature of the agencies concerned. C. T. R. Wilson has extended these researches to the nuclei produced by Röntgen rays, uranium rays, ultra-violet light, sunlight, metals in contact with a gas, ultra-violet light acting on a negatively electrified zinc plate, and the discharge of electricity from a pointed platinum wire. The author measured the supersaturation required to produce condensation by the sudden expansion of a given volume of saturated air until a fog or shower of drops was produced. He found that the action of strong X-rays on the gas differs from that of weak rays merely in the number of nuclei produced, the supersaturation required to cause water to condense on the nuclei remaining unaltered. Uranium compounds, whether inside the expansion apparatus in immediate contact with the gas or in a glass bulb outside produce nuclei requiring four-fold supersaturation, as in the case of X-rays. When the expanded air is exposed to an electric field the clouds are eliminated, owing to the fact that the nuclei are charged, and are therefore rapidly removed along the lines of force. The only uncharged nuclei are those obtained by the action of ultra-violet light on moist air and the action of metals on air.

[Wilson, *Proc. Roy. Soc.*, No. 405.]

New Sources of Becquerel Rays.—The researches on the active principle concerned in the crypto-radiation of pitch-blende, commenced a few months ago by P. Curie and

Digitized by Google

Mme. Curie, have been continued by them and G. Bémont with somewhat sensational results. In addition to the supposed new metal "polonium," which resembles bismuth in its general chemical properties, the authors claim to have discovered another, whose chemical reactions are those of barium. But, although it is always found associated with barium, its separate identity is made exceedingly probable by three circumstances. In the first place, barium itself exhibits no radio-activity. Secondly, the activity of the chloride of the new substance, mixed up as it is with barium chloride, may be considerably enhanced by repeated precipitations with alcohol. As obtained from the pitchblende, its radio-activity, measured by its power of imparting an electric conductivity to air, is about 60 times that of metallic uranium. After a few precipitations it becomes 900 times more effective. In the third place, the spectrum of the substance shows a line not due to barium, and this line becomes more and more prominent as the activity is increased by fractional precipitation. The authors have not succeeded in completely eliminating the barium. If they did they would probably obtain a substance of enormous radio-activity, which they propose to call "radium." The most important discovery of all is that the two new substances are capable of producing a photographic impression in half a minute instead of several hours, like uranium and thorium, and that they are, like Röntgen rays, capable of exciting fluorescence on a platino-cyanide screen. Here we have apparently a source of light requiring no supply of energy to maintain it, and if these substances do infringe the second law of thermo-dynamics the consequences cannot be over-estimated.

[CURIE, MME. CURIE and BÉMONT, *Comptes Rendus*, No. 26, 1898.]

Uranium Radiation.—At a time when Becquerel rays are attracting the closest attention of scientific men, it is very useful to have a careful and exhaustive investigation into the characteristics of uranium rays. This has been provided by E. Rutherford. His observation that uranium rays exhibit neither refraction nor polarisation removes the only distinction which hitherto was thought to separate the properties of these rays from those of Röntgen rays. The author's work deals more particularly with the power of rendering gases electrically conducting, and he shows that all the facts are consistent with the theory of ionisation, which involves the production of charged carriers throughout the volume of the gas, the existence of a saturation current, the partial separation of positive and negative ions, and the proportionality between the ionisation, the intensity of radiation, and the pressure. Experiments with a gradually increasing number of layers of the same aluminium foil show that uranium radiation is complex, and that there are present at least two distinct types of radiation—one that is very readily absorbed, and the other of a more highly penetrative character. This exhibits another analogy to X rays. The author calls the first kind the α-radiation, and the second kind the β-radiation, and shows that aluminium is 100 times more transparent to the latter than to the former. The author does not hazard a guess at the source of energy of uranium radiation, beyond referring critically to Thomson's suggestion of a re-grouping of the constituents of the atom. It might be expected that the rate of such a re-grouping would vary with the temperature, which uranium rays do not. What we know is that uranium, thorium and their compounds behave like anti-cathodes in an X-ray tube. The question remains: What are the rays which impinge upon them?

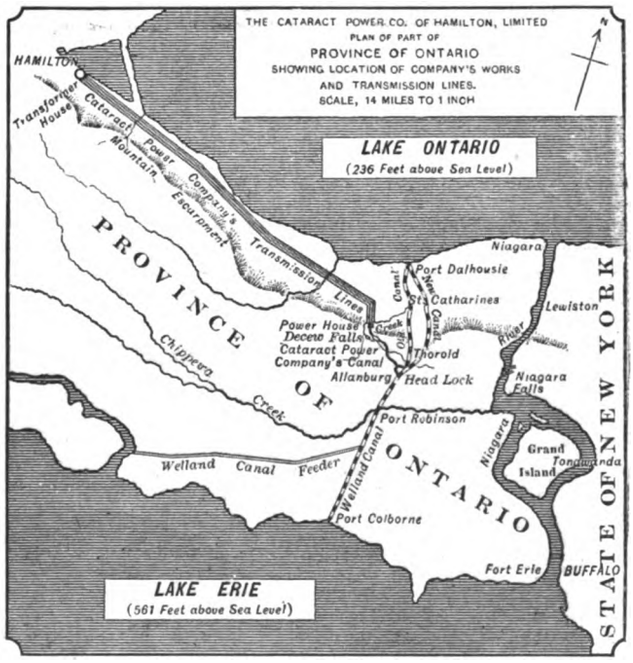
[RUTHERFORD, *Phil. Mag.*, January, 1899.]

An Aerial Underground Cable.—According to the *Énergie Électrique* the Paris Edison Co. has constructed a tunnel between its station at St. Denis, outside Paris, and the Avenue Trudaine central station, in order to run bare 2,100 volt cables between the two, and actuate a pair of 1,200 kilowatt continuous-current transformers in the latter, the present plant being overloaded. The tunnel is 6ft. high, so that a workman can walk through easily from one end to the other. This man is to be completely dressed in india-rubber.

THE HAMILTON 20,000 VOLT POWER TRANSMISSION.

A very large-power transmission plant has recently been put into operation on the Canadian side of the Niagara river, by the Cataract Power Co., of Hamilton. It is of especial interest, owing to the high-pressure of 20,000 volts, which is employed on the transmission line, and for the distance over which the power is conveyed. The generating plant is at Decew Falls, about 12 miles west of Niagara Falls and a few miles south of the shore of Lake Ontario (*see* map). This point is 85 miles distant from Hamilton, to which place the power is transmitted. The power is really a part of that of Niagara Falls, the water being taken from Lake Erie and discharged into Lake Ontario, and the immediate source being a feeder of the Lake Erie level of the Welland Canal, from which the water is taken at Allanburg. The power-house stands at the foot of a high escarpment, which can be traced for many miles east and west, forming as it does the edge of the table-land that serves, so to speak, as a dam for the waters of Lake Erie, and through which the Niagara stream has cut its famous gorge.

The Hydraulic Equipment.—The water is brought from Allanburg to the edge of the escarpment by a canal about 4½ miles in length, cut in the clay, with a minimum cross-



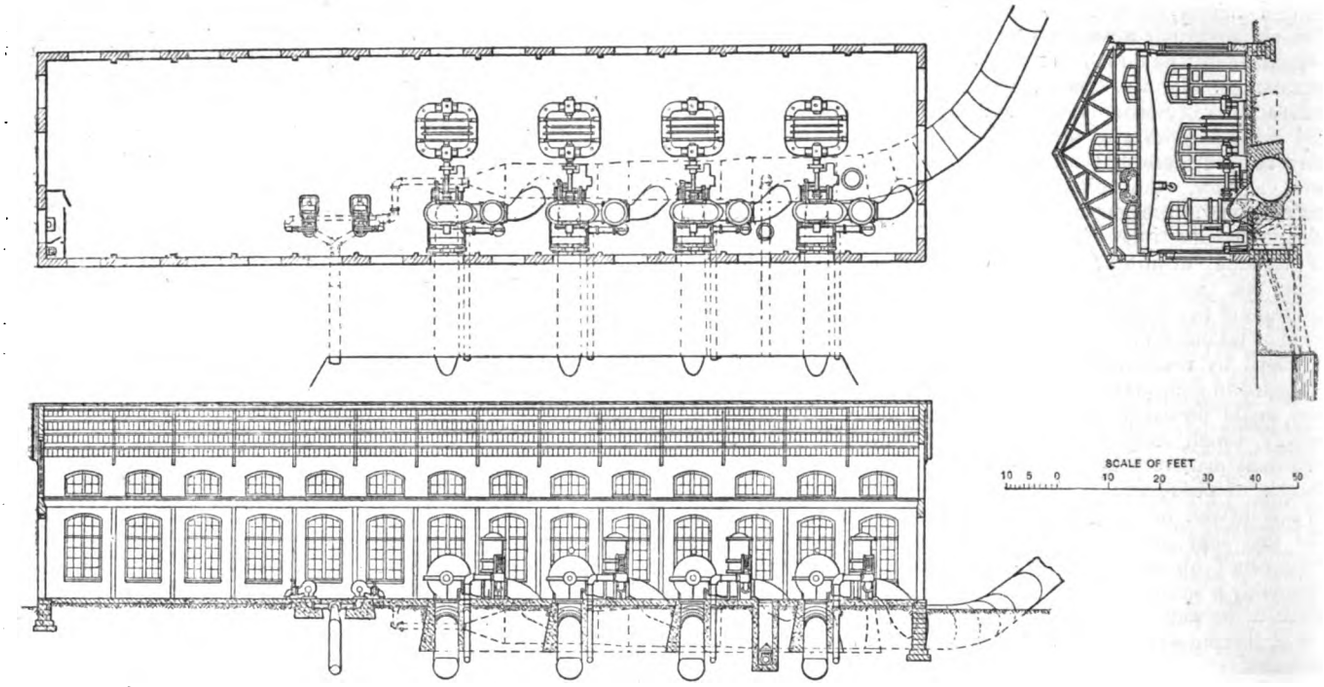
The Lake Erie—Lake Ontario Hydraulic Power District.

section of about 97½ sq. ft. below the water level, the canal being 13ft. wide at the base, the sides having a 1½ slope and the normal depth being 5ft. of water. At one point a valley is crossed by a trestle work carrying a rectangular, closed, wooden flume, which is maintained under a slight head to keep the whole of the flume wet. At the lower end of the canal there are three storage reservoirs, one natural and two artificial, giving an aggregate surface for storage of 1,250,000 sq. ft. area. From the forebay, the water is carried down the inclined surface of the escarpment to the power-house in a steel penstock 750ft. in length; the diameter of this pipe varies from 7½ft. to 8½ft. It is supported entirely from the upper end, where it is embedded in concrete in a channel cut in the rock. This arrangement was made necessary by the lack of proper anchorage points at the bottom of the slope. About two-thirds of the way down the hill there is a horizontal shelf, and at this point there is placed a slip joint to allow for temperature changes. This joint, in addition to taking care of the expansion and contraction, is so designed as to support that portion of the pipe below it, so that the whole pipe, expansion, joint and all, is hung from the top. The pipe will be covered with a wooden sheath to prevent the formation of ice at times of light load.

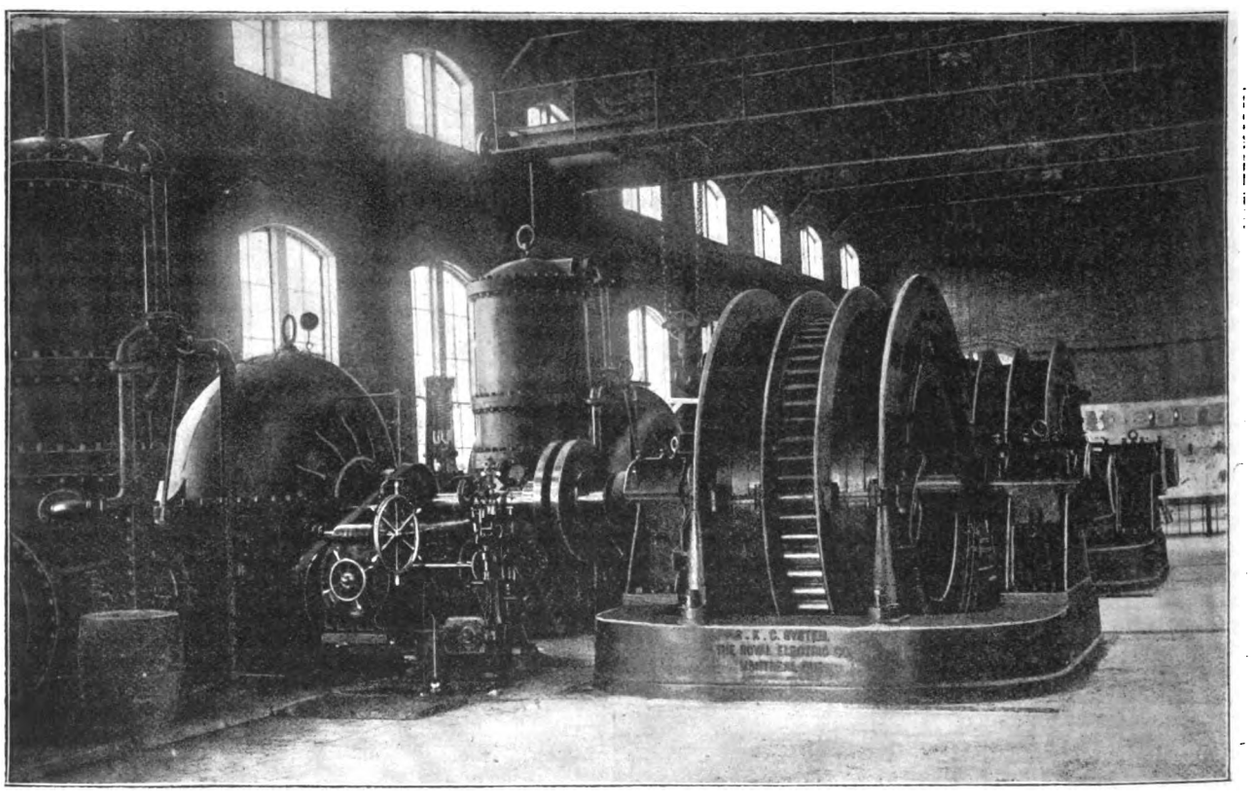
Digitized by Google

The Power House.—The power house, nestling in the valley of Twelve-Mile Creek, into which the tail-water discharges, is a plain brick structure, 174ft. long and 42ft. wide, covered with a roof supported on steel trusses. The penstock receiver runs under the floor, with four vertical branches curving over in quarter turns to the main wheels, and beyond them two similar branches for the exciters. The main gates are 36in. in diameter, and were built, as were the wheels, by the Stilwell-Bierce and Smith-Vaile Co. They are each operated by a hydraulic ram under penstock pressure, and are not fitted with by-passes. The four-way valve for operating the ram is moved by a long handle, on the other side of which is a 12in. spring-closed relief valve, there being no air chambers on the penstock.

The wheels are of a different style from those generally supplied by this Company, and may be described as an inward-flow, radial type. One of the interesting features of this plant is the employment of the reaction type of turbines with the very high head of 260ft. The intake pipe is horizontal, and the draft tube passes vertically down through the floor and is sealed in the tail race to give the added head of 14ft. by suction. The governing gate is a ring of the register type between the guide chutes and the buckets of the runner, and it is moved axially by two rods connected with the



Plan and Elevations of Power House.



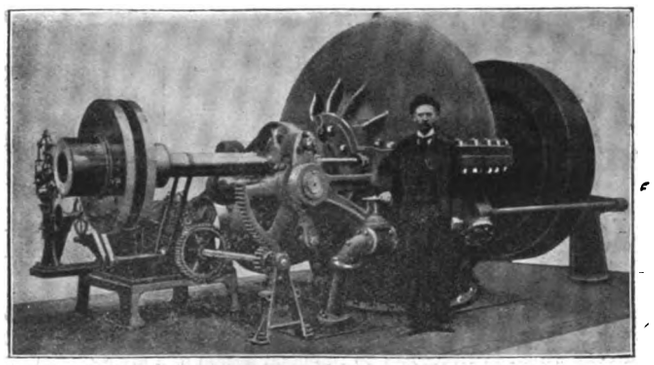
Interior of the Power House.

Digitized by Google

governor mechanism. The governor is of the Giesler electro-mechanical type, the centrifugal balls operating electrical contacts, the currents from which in turn energise clutches driven by belting from the main shaft. The wheels are rated at 1,950 H.P. each at 400 revolutions per minute, under the normal head.

On one of the shafts is a 7½-ton flywheel, with an outboard bearing, and the other end is attached through an insulating coupling with the electrical generator. The latter are of the inductor type, and were supplied, as was all the electrical equipment, by the Royal Electric Company, of Montreal. The inductor weighs 15 tons, and is fitted with ten poles on each ring, and, therefore, at the speed of 400 revolutions per minute, generates 66⅔ ∽ per second. The machines generate two phases at 2,000 to 2,400 volts, the windings being, as is customary with these machines, of the coil type and not distributed. These coils are wound of bare copper strip with mica insulation between the turns, which construction will stand long-continued over-heating without deterioration.

The machine switchboard has three panels of white marble, one for the exciters and one for each of the generators now in place. The generator panels have no live contacts on the face of the board, and are each equipped with one voltmeter, a switch by which this instrument may be thrown on to either phase, two main ammeters, one for each phase, and one continuous-current ammeter in the field circuit. Switching is accomplished by two double-pole, double-throw slide switches, one for each phase, the double throw being from one set of 'bus bars to the other. Beside these instruments there are the usual field rheostats. There are no fuses on the generator board, a short circuit being considered less dangerous with



One of the Main Wheels with Governor, Fly-Wheel and Coupling.

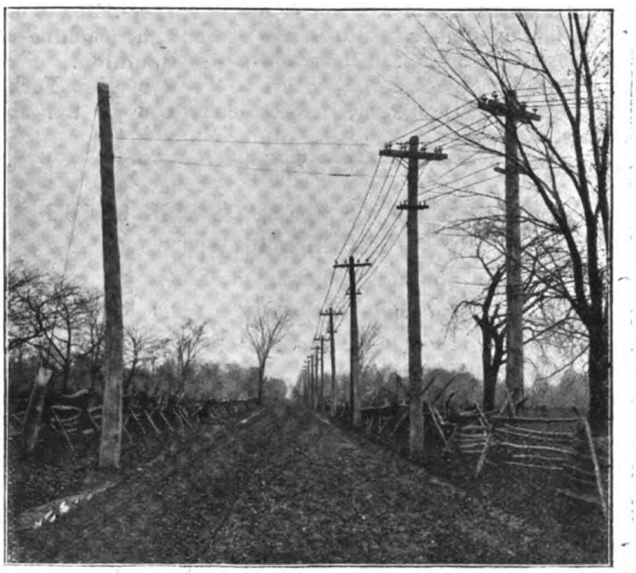
these machines than a sudden throwing off of the load by a fuse blowing with the turbine gate full open. The exciter panel coutains the usual instruments and switches for operating two continuous-current shunt machines in parallel on the exciter 'bus bars.

The exciters themselves consist of two 30-kilowatt, four-pole, 70-volt machines, built by the Crocker-Wheeler Company, driven at 1,000 revolutions per minute by individual turbines to which they are direct-coupled, each exciter unit being of sufficient capacity to excite the full equipment of four generators. These turbines are hand-governed.

One of the most interesting parts of the station is that devoted to the step-up transformers for obtaining the 20,000 to 24,000 volts delivered to the line. Two-phase currents being used on the line, a plain battery of single-phase transformers is connected on each phase. Each battery consists of five 200-kilowatt Stanley transformers, immersed in "mineral seal" oil in heavy boiler-iron cylindrical cases, about 4ft. in diameter and 6ft. in height. The transformers are cooled with water, which is taken from the penstock and circulated through pipes inside the transformer cases.

Each transformer is fitted with a marble switchboard supplied with switches on both the high and the low-tension sides; the latter are of the ordinary slide type, double-throw from one set of 'bus bars to the other, and mounted on the backs of the panels. The 20,000-volt switches are more interesting. They are of what is called the stick type, consisting of a wooden pole about 4ft. long, carrying at its upper end a receptacle or socket which may be pushed up around a downwardly projecting contact finger on the board. The socket on the pole is connected, by a heavily-insulated, flexible cable with a plug permanently screwed into its receptacle. The socket is provided with guides, which run under hard rubber slides when the socket is attached to or removed from the finger. The tips of both fingers and sockets are made of non-arcing metal. It is not intended that these switches shall be opened with the load on, but the load will first be removed by the low-tension switches. The others will then only open the magnetising current of the transformers and the capacity current of the line. Each high-tension stick may be attached to either one of two fingers, connecting to either one or the other of the duplicate lines which will eventually be established. Between the two poles of the switchboard for each transformer there is a heavy marble barrier. Non-arcing fuses are placed on both primary and secondary sides of each step-up transformer.

The Line.—The line, as noted above, is of a rather unusual type for such long transmissions, namely, two-phase. The 25 per cent. economy of copper, which could have been obtained by a three-phase line with the same potential differ-



The 20,000-volt Two-Phase Pole Line.

ence between wires, is sacrificed for the reduced interference of unbalanced loads which will be obtained by the arrangement adopted. The four No. 1 medium-drawn bare copper wires are supported on a single cross-arm, the two phases being respectively on the two sides of the poles, and the wires 18in. apart. The poles vary from 40ft. to 50ft. in length, have tops with a minimum diameter of 8in., and are spaced 90ft. apart.

Protection against lightning is obtained by a barbed wire the whole length of the line, stapled to the tops of the poles and earthed at each pole. At the terminals, banks of Stanley lightning arresters and choking coils are used, there being 30 gaps in series between each wire and earth. The insulators are triple-petticoat porcelain, tested in the ordinary way to 65,000 volts before use. The pins are of "locust," prepared in oil, and are fastened into the cross-arm with a wooden peg, the object being to avoid all unnecessary metal near the wires. A two-wire telephone line is mounted on a lower cross-arm, and is frequently transposed, the power wires not being transposed or spiralled. For a large part of the distance the line follows the route of the Grand Trunk Railway.

The Transformer Sub-Station.—At Hamilton the line runs into a specially constructed brick transformer station on Victoria-avenue. After passing through the arresters, each wire terminates in a panel of the line board provided with stick switches as at the other end. One-half of the room is occupied by two batteries of five 175 kilowatt transformers, similar to those at the power station, except that they are air-

Digitized by Google

cooled instead of water-cooled. The boiler-iron cases are fitted with a ring of vertical tubes open at either end, and the transformers set over a duct into which air is blown by a Sturtevant blower coupled to a two-phase motor. The air rises through the tubes and discharges from the tops of the cases, cooling the oil, which in turn cools the copper and iron of the transformer. Each transformer is fitted, as are those at the power station, with switchboard panels having high-tension and low-tension switches. The high-tension side is also fused at this point with enclosed 20,000-volt, 18-ampere fuses, 15in. in length.

The Company is now supplying power to the incandescent service of the Hamilton Electric Light and Power Co., and still another switchboard is in use at the transformer sub-station, for the out-going 2,000-volt feeders. These feeders are provided with two independent wires on each phase, except those which will be devoted exclusively to power service, which will have three-wire two-phase lines. The lighting loads are balanced and boosted at the Electric Light Company's station. The old house-to-house 1,000 to 50 volt, 133⅓ ∼ transformers of the lighting company have been replaced by 2,000 to 100 volt 66⅔ ∼ transformers in larger units, with a better grouping of the secondary loads. The Company expects later to carry a considerable power load to drive the arc light machines and also several, if not all, of the tramways of Hamilton.

We are indebted to the *Electrical World* of New York for the illustrations and information contained in the above article.

IMPROVEMENTS IN MAGNETIC SPACE TELEGRAPHY.*

BY DR. OLIVER LODGE, F.R.S.

(Concluded from page 367.)

Magnifying Telephone.

Instead of using the vibrating coil to affect a soundboard direct, it was obvious that it might be used first to affect a microphonic contact in a local battery circuit, and thus cause

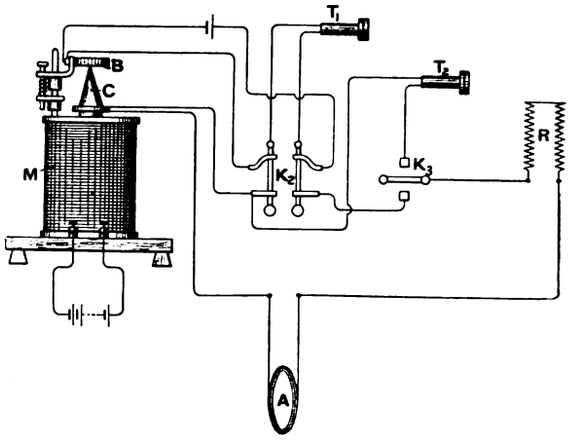


Fig. 6.

fluctuations in a stronger current than that induced from a distance, and so send on a more vigorous disturbance to another telephone, and thus cause a louder noise. For this purpose, after several microphonic transmitters had been tried, a Berliner was ultimately chosen, and arranged at B in Fig. 6. Here the ordinary telephones are arranged so that the disturbance can be heard either direct without magnification or after magnification, and then the received disturbance can be compared with the magnified disturbance. The telephone T_1 serves for both determinations, according to whether the keys are up or down. The telephone T_2 was a duplicate of the same make, and was switched into either circuit when T_1 was out of it, so as to keep everything similar. It was found during the experiments that T_2 was unimportant; the resistance and inductance of the rest of the circuit were great in comparison.

In these early trials the tripod merely pressed against the mica disc of the transmitter; but the mica was now removed and the tripod attached to the coil pressed against the carbon plate instead; but this was no improvement. Hitherto the coil was *pressed* up, resting on elastic pellets below, and was under considerable constraint; now, finally, the tripod was attached rigidly to the centre of the carbon plate of the Berliner transmitter, and the coil

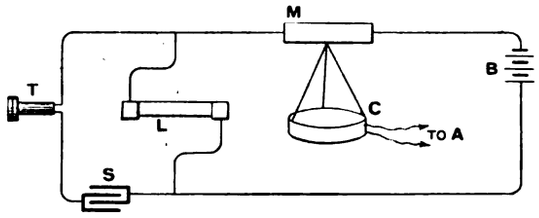

Fig. 7.

was allowed to hang freely in the magnetic air gap. This was much the best plan; but a spiral spring pressing upwards is still generally used to support the weight of the coil and to regulate the dominant pitch appropriate to the disc and coil as a vibrating system.

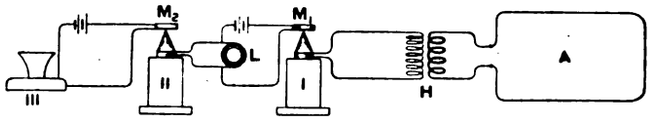

Fig. 8.

The method of connecting the magnifier to the telephone listened to was also modified, and was frequently as in Fig. 7, where T is any telephone, diagrammatically indicated, M is the Berliner microphonic transmitter, with receiving coil hanging on a tripod

from its carbon plate, B is a battery of three storage cells; and L is a self-induction coil, without iron, which carries most of the steady current which is necessary to the good action of a microphone, but

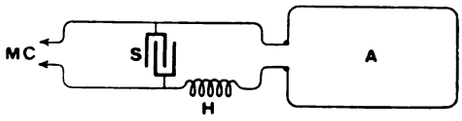

Fig. 9.

diverts the jerks and fluctuations mostly through the telephone, even though this be of high resistance.

Sometimes a condenser, S, was inserted in its circuit too, with the object of assisting through the telephone fluctuations of a

definite pitch, and of other pitches not too far removed from that. A transformer could be used instead of the self-induction shunt, but the advantage of a transformer is more felt on long lines; for

a compact apparatus it serves too, but it wastes more power than the L shunt.

The arrangement shown in Fig. 8 was tried as receiver at my

fine-wire suspended coil of the first magnifying telephone I. The currents from its transmitter, M_1, are taken to the fine-wire coil of the next magnifier, II., shunted by the low-resistance self-induction

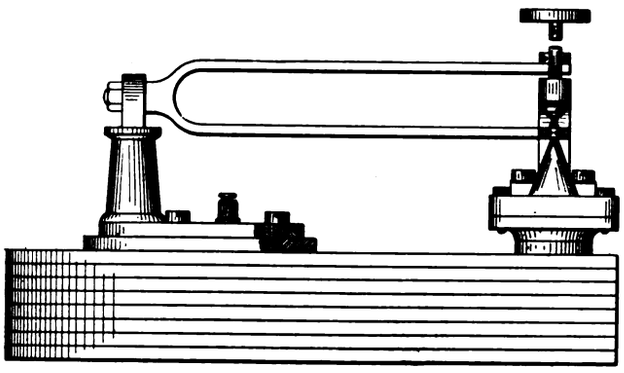

FIG. F.—Syntonic Magnifying Telephone, with tuning fork; suspended coil working a microphone. Compare Fig. 10.

coil L. III. is the final telephone of the series, viz., an ordinary Western Electric loud speaker (2 ohms), in series with the transmitter M_3. Under these circumstances the signals could be heard with the ear 2in. from the funnel of III.

But the hedgehog wasted a lot of power; its volume of iron being considerable, and the hysteresis and eddy losses at high frequency being very marked. An improved arrangement consisted in interposing a 20-microfarad condenser (the largest then available, kindly lent by Dr. Alex. Muirhead). This was not enough to tune up the circuit, except when the thin-wire circuit of the hedgehog was unclosed. So the plan shown in Fig. 9 was adopted, and was a decided improvement. M C is the magnifying arrangement, as before. H is the thick wire of the hedgehog, inserted merely as extra self-induction. S is a condenser having a capacity of 20 or 21, or sometimes as much as 24, microfarads (a

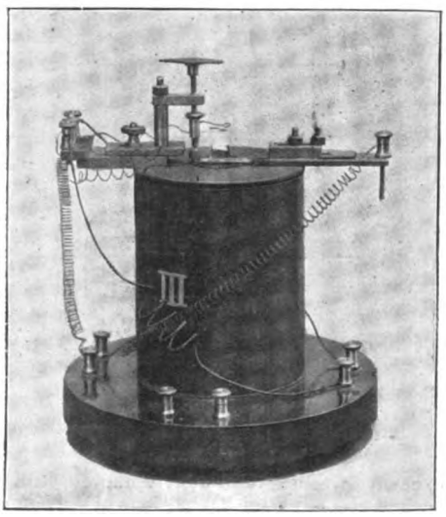

FIG. G.—Photo raph of the Telephone Magnifier with coil suspended by a tuned reed. Compare Fig. 10.

small plug condenser being added in parallel to vary and improve the tuning).

Thus the note was enhanced by resonance, and the signals became almost loud. (The tuning-reinforcement at the College end happened, however, on this particular occasion to be rather poor.)

This must serve as a sample of a great number of experiments, made with all manner of condensers and different notes; an especial amount of variation being practised at the sending end. It is to be remarked that fine-wire coils to the telephones are by no

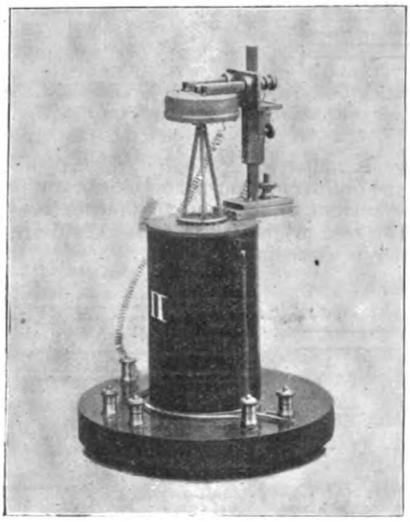

FIG. 11.—Photograph of Single-pole Magnifying Telephone with vibrating coil operating a Berliner transmitter.

means the best for this particular purpose, and afterwards ribbon coils of thin aluminium strip were used instead. Transformers and L shunts could then be dispensed with; but small telephonic transformers are still usually employed, to prevent the constraint exerted on the hanging coil by a steady current passing through it. Small transformers don't waste much, and a little waste of power matters nothing where there is a local battery.

The Berliner or such-like granular transmitters, though serving well to magnify an already audible current, do not always pick up and magnify an inaudible one, and, moreover, they do not discriminate between an intended and accidental vibration. For this

Digitized by Google

purpose a better and more precise apparatus has to be constructed —viz., the reed or the tuning-fork magnifying telephone, with only a single pair of carbon contacts. This is shown in Fig. 10, and its essence is that the coil is hung to a reed or fork or vibrator of definite pitch, and carries also a pellet of carbon which presses lightly upward on another fixed pellet, thereby constituting a single-contact microphone. Such an arrangement, as is well

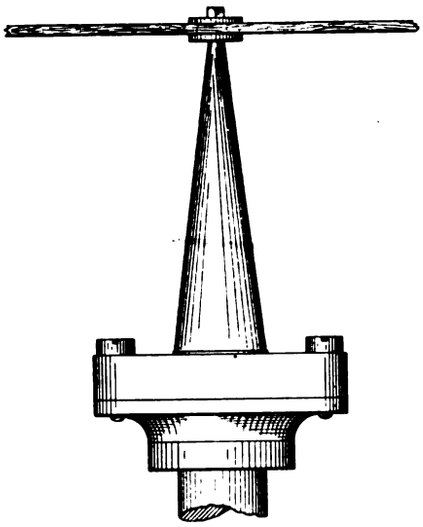

FIG. 12.—Mounting of Coil and Pole-piece of Sound-board Telephone.

known, is excessively sensitive to utterly imperceptible mechanical disturbances, and the minutest fluctuations of current now passing through the hanging coil give ultra-microscopic tremors sufficient to vary the resistance of the light carbon contact perceptibly; the energy of a single-cell local battery being thus brought into action,

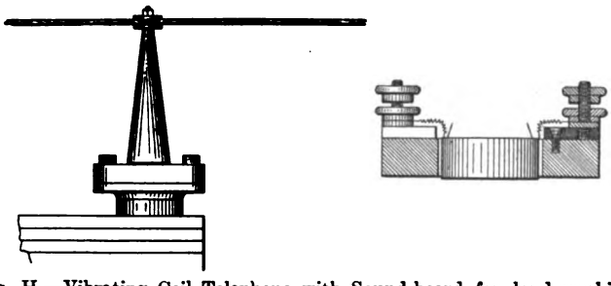

FIG. H.—Vibrating Coil Telephone with Sound-board, for loud-speaking or other signalling. Compare Fig. 12.

enough energy is imparted to disturb (through another hanging coil) one of the ordinary granular transmitters, which then passes on a stronger current to the loud speaker, or the "call." Or it may be that two reed magnifiers in series are desirable, when the received current is exceedingly faint.

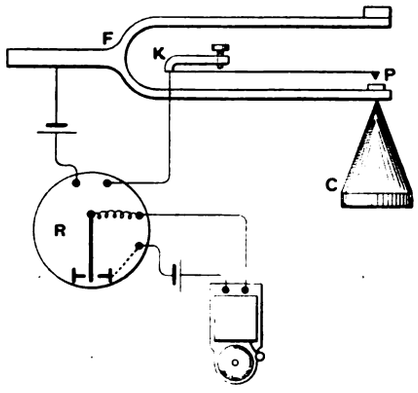

FIG. 13.

The single-point magnifiers do not carry big currents, and they require delicate, though easy, adjustment; but when properly made and adjusted they work extremely well with pure tones. The multiple-contact microphones work better for articulate speech, as is well known. The magnifying transmitter is shown in Fig. 11. I find graphite carbon the best for these single contacts, and I am indebted to Mr. Swan, to Le Carbone, and to Mr. Acheson for several specimens of soft carbon, which answer much better than the harder arc lamp variety.

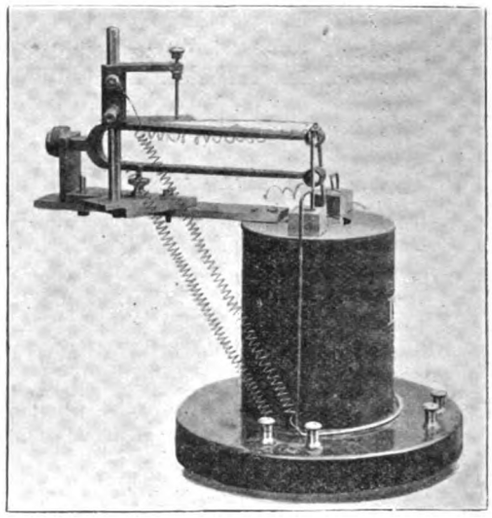

FIG. J.—Photograph of the Electromagnetic Syntonic Call Telephone, which breaks the circuit of a relay and so rings an electric bell when it receives the current of right frequency from the magnifiers. Compare Fig. 13.

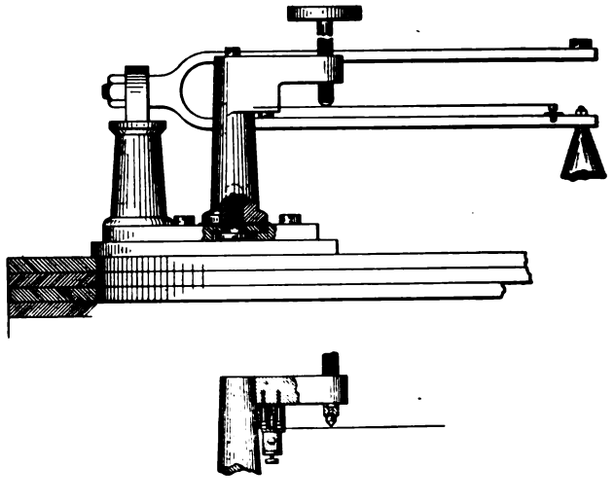

FIG. K.—Details of Syntonic Call Telephone, showing the dancing contact on one of the prongs. Compare Fig. 13.

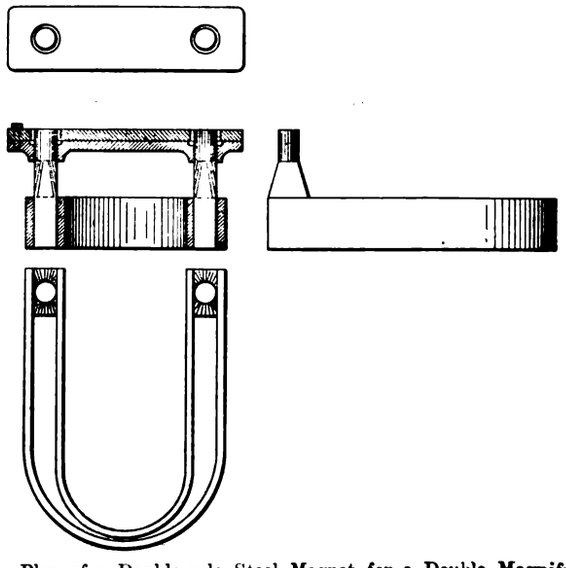

FIG. L.—Plan of a Double-pole Steel Magnet for a Double Magnifying Telephone.

The last telephone of the series has been so far represented as one of ordinary pattern, but it is obvious that the vibrating coil attached to a wooden sound-board may be employed, like Fig. 12;

Digitized by Google

and, further, that a combination of such sound-board telephone may have an important application to the human voice and the acoustics of buildings—a different subject, into which I will not now further go.

It is also manifest that when the vibrations are magnified they may be used to work a relay and ring a bell, or actuate a Morse instrument, or anything else; just as in the phonophoric receiver, for instance. I am indebted to Mr. Langdon Davies for the loan of one of his phonoporic receivers.

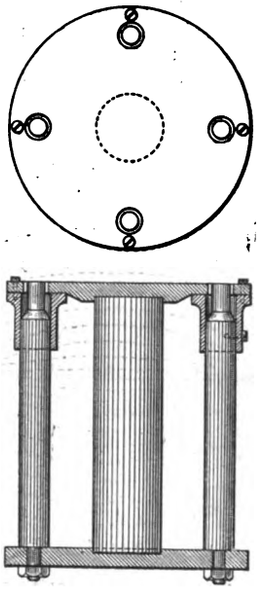

FIG. M.—Permanent Magnet with four annular pole-spaces adapted to receive the four coils of a quadruple magnifying telephone.

The bell-ringing arrangement that we at present prefer is a coil telephone of the tuning-fork pattern, so that (if protected from mechanical shaking) it shall only respond to a definite note, and not to casual currents in the line. The light coil hangs to the limb of a large tuning-fork, and on this or on the other limb is a light metallic contact which dances when the limb vibrates, thereby practically breaking a local relay circuit and letting its tongue fly

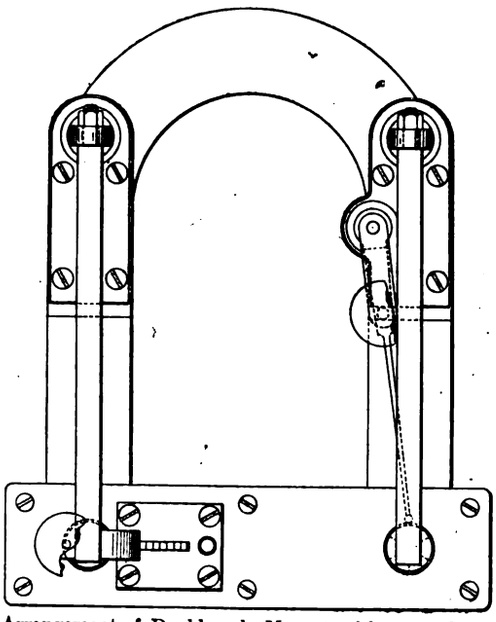

FIG. N.—Arrangement of Double-pole Maguet with one pole magnifying and the other pole "calling."

over, so as to close a bell circuit. A diagram is hardly necessary, but one is given in Fig. 13.

C is the last of the series of the suspended magnifying telephone coils.

F is a tuning-fork on firm stand.

K is also rigidly supported, and carries a thumb-screw for adjustment of spring.

P is a platinum stud contact carried by a very light spring; and this forms part of the local polarised relay circuit,

R, which rings a bell in the very ordinary way in any office where calling up is desired.

It may be thought that a light coil is hardly competent to shake appreciably the massive steel limbs of a tuning-fork; but when it is isochronously attuned to the pulsations of the received disturbance, a tuning-fork is wonderfully sensitive (even to aerial vibrations, as is well known in an ordinary resonance experiment); and the fact that it is not sensitive to disturbances of accidental frequency is wholly advantageous. The light trembling spring is, however, readily disturbed by any sort of shaking, and if the relay is too delicately adjusted it may give spurious calls due to mechanical tremors. From these it must be guarded.

Continuous working at the subject for over a year on the part of Mr. Benjamin Davies and myself, with occasional aid from instrument makers, has naturally resulted in a mass of observations and experiments. What is now published is but a fragmentary selection, but the Paper is quite long enough.

ÆTHERIC TELEGRAPHY.*

BY W. H. PREECE, C.B., F.R.S.

I have never submitted to the Institution of Electrical Engineers any record of my long and continuous researches on signalling through space. My reports have been made from year to year to Section A of the British Association. Some of them not having been printed, it is not to be wondered at that all my work is not known, and so much of it is occasionally reproduced by others. I will confine my remarks in this paper to ætheric telegraphy, and to its electro-magnetic form alone.

In 1884† disturbances—that is, stray currents producing extraneous noises on the telephone—were detected on the circuits erected over the house-tops, produced by currents in telegraph wires buried in iron pipes in the streets. Messages sent on the telegraph wire were actually read on the telephone circuit, though the wires were nowhere in contact. Exhaustive experiments were made to prove that these results were due to induction and not conduction. This was done by making the circuits metallic. They were separated from each other by a span of 80ft.

Many preliminary laboratory experiments were made with coils of many turns, but in 1885 square coils of insulated single wire, each side being of 440 yards length, were laid horizontally on the ground in the neighbourhood of Newcastle, and conversation by telephone was effected from one to the other through a space of one-quarter of a mile. Disturbances between these squares were appreciable at 3,000ft., and even at a distance of 10¼ miles between parallel lines of telegraph connecting Durham and Darlington. In 1886‡ experiments were carried out across the Severn for a length of 14 miles between Bristol and Gloucester, the parallel wires being separated by a mean distance of 4·5 miles. Primary currents of 0·449 ampere were rapidly made and broken by mechanical means, producing on the telephone a continuous note which could be conveniently broken up by a Morse key into dots and dashes, as in Cardew's vibrator. Disturbances were observed in the secondary circuit. The circuits were metallic and of many miles in length, that on the Gloucester side being completed through Stroud, and that on the Welsh side through Monmouth. Here we had just reached the limit of disturbance with the means at our disposal. It afforded a convenient measure of the range of audibility. The unexpected fact was shown that, whether the circuits were metallic or earthed at the ends of the parallels, the results were the same. This was confirmed subsequently by innumerable experiments, especially by some results obtained between Arran and Kintyre in 1894.§ All our experience since has shown that a coil of one single turn of thick copper wire, and of the largest possible diameter, gives the best result, and signals to the greatest distance. Moreover, it will be shown that the greater portion of this coil may be made up by the earth. In a single turn thus formed we have the full beneficial effect of electro-magnetic as well as of electrostatic induction, we have the advantage of earth conduction, and we reduce capacity and inductance to their minimum. In closed coils of many turns we have only electro-magnetic induction, and we make inductance a maximum. In the autumn of the same year (1886) the vast expanse of sand at Porthcawl, in South Wales, was used to further develop the law determining these effects.‡ Two horizontal squares of 300 yards per side were placed 300 yards apart, and subsequently one of them was suspended on scaffold poles 15ft. above the other, which was covered with water at high tide. No difference was detected in the strength of signals, whether the space were air or water, or a combination of air and water. Subsequent experiment

Digitized by Google

(1893) showed that through 15ft. the effect in air was distinctly better than through water.

The conclusion then arrived at was that the magnetic field extends uninterruptedly through the earth, as it does through the air, and that if the secondary circuit had been in a coal-pit it would have been equally evident. In fact, Mr. Arthur Heaviside succeeded in 1887 in communicating between the surface and the galleries of Broomhill Colliery, 350ft. deep. But subsequent experiments showed that the conclusion arrived at was not true for water, for, though we have spoken in Dover Harbour telephonically through 36ft., at 400ft. off the Goodwin Sands, no practical signals could be detected. Hence, the effect must diminish in water with some high power of the distance. A new telegraph line of copper wires running parallel to the Great Western Railway in 1886 offered convenient opportunities to experiment further.* The fact that parallel wires followed the same law as metallic coils facilitated such experiments. Horizontal coils of large diameter lying on the ground are impractical things, and I was glad to get rid of them. It was determined that with two parallel wires of 1 mile length, the primary wire being excited by 1 ampere, the limit of audibility was reached at 1·9016 miles, and that

$$x = 1{\cdot}9016\sqrt{\frac{C_1 l}{r_2}}$$

gave a fairly accurate empirical formula to determine the maximum distance, x, which should separate any two wires of length, l, C_1 being the primary current and r_2 the resistance of the secondary wire. This was amply confirmed by experiments repeated in the Severn Valley in the same year,* and it established the fact that it was advisable to use copper conductors of the largest gauge that could be obtained. It was also determined that a very important element of success was the rate at which the currents rise and fall, and that every cause of retardation, such as capacity and self-induction, should be eliminated from the circuits.

A great many experiments were made in Lisvane, in Glamorganshire (1887), Loch Ness (1892), the Conway estuary (1893), Frodsham, on the estuary of the Dee (1894), Wimbledon (1894).† But the most satisfactory results were obtained in the Bristol Channel (1892), between Lavernock and Flat Holm, 3·3 miles apart, between which places messages passed freely.‡ In fact, at the present time this line has been re-erected and made permanent. It is in actual practical daily use, and has never failed ever since it was established. The Pyke and Harris alternator, which was used in 1892, has been replaced by dry cells. The frequency has been raised to 400. The rate of rising and falling of the current has been immensely improved. The resistance of the circuit has been made as low as possible. There is no measurable capacity, and self-induction is eliminated. Hence the signals are simply splendid, and their rate of working dependent only on the skill of the operator.

The conception of the function of the earth as the completion of the circuit of a single coil has been thoroughly formulated. The earth acts simply as a conductor, and *per se* it is a very poor conductor, deriving its conducting property principally, and often solely, from the moisture it contains. On the other hand, the resistance of the "earth" between the two earth-plates of a good circuit is practically nothing. Hence it follows that the mass of earth which forms the return portion of the circuit must be very great, for we know by Ohm's law that the resistance of a circuit increases with its specific resistance and length, and diminishes with its sectional area. Now, if the material forming the "earth" portion of the circuit were, like the sea, homogeneous, the current-flow between the earth plates would follow innumerable but definite stream lines, which, if traced and plotted out, would form a hemispheroid. These lines of current have been traced and measured. A horizontal plan on the surface of the earth is of the form illustrated in Fig. 1, while a vertical section through the earth is of the form shown in Fig. 2. With earth plates 1,200 yards apart these currents have been found on the surface at a distance of half a mile behind each plate; and, in a line joining the two transversely, they are evident at a similar distance at right angles to this line.

Now, this hemispheroidal mass could be replaced electrically by a resultant conductor (R, Fig. 2) of a definite form and position; and, in considering the inductive action between two circuits having earth returns, it is necessary to estimate the position of this imaginary conductor. This was the object of the experiments at Frodsham. If the material of the earth be variable and dry the hemispheroid must become very much deformed and the section very irregular, the lines of current-flow must spread out further, but the principle is the same, and there must be a resultant return. The general result of the experiments at Frodsham indicate that the depth of the resultant earth was 300ft., while those at Conway are comparable with a depth of 350ft. In the case of Frodsham the primary coil had a length of 300ft., while at Conway the length was 1,320ft. At Loch Ness and between Arran and Kintyre, where the parallel lines varied from two to four miles, the calculated depth was found to be about 900ft. The depth of this resultant must, therefore, increase with the distance separating the earth-plates, and this renders it possible to communicate by induction from parallel wires over much longer distances than would otherwise be possible.

In establishing communication by means of induction there are three dispositions of circuit available, viz.: (*a*) single parallel wires to earth at each extremity; (*b*) parallel coils of one or more turns; (*c*) coils of one or more turns placed horizontally and in the same plane. The best practical results are obtained with the first arrangement, more especially if the conformation of the earth admits of the wires being carried to a considerable height above the sea, whilst the earth-plates are at the sea level. By adopting this course the size of the coil is practically enlarged, and even if it be necessary to

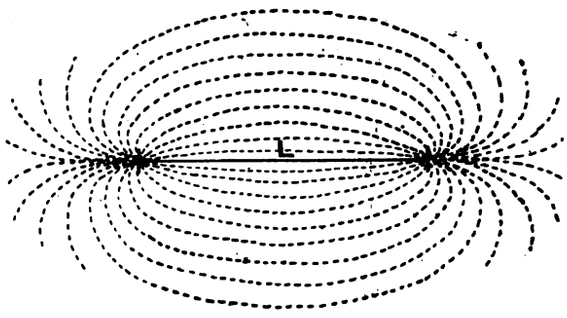

FIG. 1.

increase the distance between the parallel wires to effect this object the result is still more beneficial. Two wires of a definite length were first made up into two coils forming metallic circuits, then uncoiled and joined up as straight lines opposed to each other, with the circuit completed by earth. The inductive effects, and the distance between which they were observable, was very many times greater with the latter than with the former arrangement.

One very interesting fact observed in Loch Ness in 1894 was that there was one particular frequency in the primary circuit that gave a decided maximum effect upon the telephone on the secondary circuit. It was a case of tuning. It was so effective as to secure the transmission of speech across a space of 1¼ miles.

Effects of resonance were observed during the experiments in Arran in 1894.* A metallic circuit was formed, partly of insulated wire 500ft. above the sea level, and partly of ordinary line wire, the rectangle being two miles long and 500ft. high. Wires on neighbouring poles at right angles to the shorter side of the rectangle, although disconnected at both ends, took up the vibra-

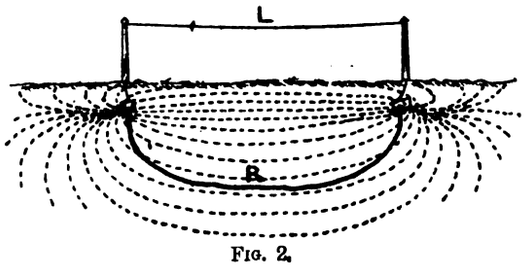

FIG. 2.

tions, and it was possible to read all that was signalled on a telephone placed midway in the disconnected circuit by the "surgings" thus set up.

In March, 1895, the cable connecting Oban with the island of Mull broke down. A gutta-percha-covered wire, 1½ miles long, was laid along the ground from Morven, on the Argyllshire coast, while on Mull the ordinary overhead iron wire connecting Craignure with Aros was used. The mean distance separating the two wires was about two miles. There was no difficulty in communicating. Public messages were sent for a week until the cable was repaired.†

Perhaps the most important experiment attempted was that to communicate between England and Ireland. A circuit was made up from Carlisle to Haverfordwest, and another in Ireland from Belfast to Wexford.‡ The whole telephonic system of the

country was stopped from midnight to two a.m. one Sunday morning in June, 1895. Attempts were made to signal, but it was impossible to distinguish a signal through the wonderful, incessant, and strange, sounds that filled the telephone and overpowered everything else. No telegraph was at work anywhere. The hum of two or three electric light installations working on the alternate-current system was evident, but there was a weird, strange babel of noises that was mysterious and disappointing. I am strongly of opinion that these sounds were due to disturbances excited by primary electrical effects outside our globe. I have not thought the experiment worth repeating. It can have no practical value, but I had arranged in the event of its success to communicate between England and Europe, and then between Europe and America.

ELECTRICITY WORKS ACCOUNTS.

The Woolwich District Electric Light Co. (Limited).

Electricity supply in Woolwich was commenced in September, 1893, therefore the accounts which are dealt with in our table are those of the third and fourth completed years of working.

The total received capital of £16,000 has been raised, £10,000 by the issue of 10,000 £1 shares, and £6,000 on Four per Cent. Debentures. Of this total amount £15,745, representing £42·6 per kilowatt of plant capacity, has been expended on capital account, no less than £30 of the £42·6 total per kilowatt being on plant.

Corresponding with an increase in the number of the consumers of from 69 to 76 during 1897 the equivalent 8 c.p. lamp connection had risen from 3,878 to 5,023, an increase of about 30 per cent., while the output for 1897 was 77,150 units sold as compared with 75,929 in 1896, a rise of but 1·6 per cent. It is evident, therefore, that the majority of the lamps added to the circuit in 1897 were connected near the end of the year, and had little influence in increasing the output. In consequence of this and the failure of the condensing plant the accounts show a disappointing state of affairs for 1897. The already high costs of 4·88d. per unit in 1896 are shown by the accounts to have risen in the succeeding year to 5·69d. *All* the items of cost are responsible in some degree for this result, as they all without exception show increases.

The ultimate results are that although the tariff remained unchanged the ratio of costs to revenue had risen from 86·5 to 96 per cent., and instead of a working profit of £240 as in 1896, the figure for 1897 was only £77. Nothing has been written off for depreciation or reserve, but £204 was paid in interest, leaving a deficit of £105.

Contracts had been entered into by the company for the provision of new condensing plant, extension of mains and plant, and for the conversion of the system from high pressure alternating to low pressure continuous current, and it was anticipated that these extensions would have been ready for this winter's load.

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal 1861—1876).

Published every Friday, Price Sixpence; Post Free, Sixpence Halfpenny

Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone: 949 Holborn. *Telegrams:* "Electrician Newspaper London."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "The Electrician," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "The Electrician" *Printing and Publishing Company, Limited, and be crossed "Coutts and Co."*

All Editorial letters to be addressed to The Editor.

All letters for insertion in "The Electrician," *or containing questions, must be accompanied by the name and address of the writer as evidence of good faith. No notice whatever is taken of anonymous communications.*

The Electrician *" is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices, as above.*

New Volumes of "The Electrician" *commence in April and October.*

Subscription Rates.—The Rates for Subscriptions to "The Electrician" are as under:—

	Year	Half-Year	Quarter	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.	

"The Electrician" *offers exceptional advantages to Advertisers.* It has by far the largest circulation of any English Electrical paper, and circulates all over the World. *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

Trade Advertisements *intended for the current issue must reach the Office not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday. Wrapper Advertisements by Wednesday morning.*

Official Announcements, Auctions, *and* Small Advertisements *accepted up to 6 p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct o "The Electrician" *Printing and Publishing Company, Limited. The well-known* "Electrician" Series *of Standard Electrical Works at present consists of—*

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young, M.I.E.E. Price 10s. 6d., post free; abroad 11s.

THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By Messrs. H. K. C. Fisher and J. C. H. Darby. Price 6s. net; abroad, 6s. 3d.

BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH. Edited by C. E. S. Phillips. With an introduction on the history of Crookes Tube and Röntgen Ray work, and a chapter giving "Practical Hints," on the subject.

LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS. By F. C. Raphael. Price 5s., post free.

MOTIVE POWER AND GEARING. By H. Tremlett Carter. Price 12s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson. Price 12s. 6d., post free.

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. Fleming, M.A. F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d., post free 12s. *Vol. II. is nearly ready.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. Fleming. VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. New Edition. Price 12s. 6d., post free. VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. 98 original illustrations, price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. Snell. 10s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. George Gore. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. Weymouth. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By Gilbert S. Ram. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Gnipel and H. M. Kilgour. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d., post free. New edition in the press.

"THE ELECTRICIAN" PRIMERS. In Two Vols. Paper covers, 2s., post free, 2s. 3d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d.

WIRELESS TELEGRAPHY: Signalling across Space without Wires by Electric Waves. By Dr. O J. Lodge. Enlarged Edition. Price 2s. 6d. net.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c. By A. C. Curtis-Hayward, B.A. Price 3s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont. Price 2s. 6d., post free.

FULL CATALOGUE POST FREE ON APPLICATION.

"ELECTRICIAN" SERIES FORTHCOMING BOOKS.

ELECTROMAGNETIC THEORY, VOL. II.—By Oliver Heaviside. The second volume of this important work is in an advanced stage, and will be ready shortly.

PRACTICAL TELEPHONY.—By Dane Sinclair and F. C. Raphael.

PRIMARY BATTERIES.—A work on this subject will shortly be published, bringing the theory and practice of the Primary Battery up to date. The book will be fully illustrated.

SECONDARY BATTERIES.—By E. J. Wade. Fully illustrated. The Author in this work will deal briefly with the theory and fully with the chemistry, design, construction and manufacture of secondary batteries or accumulators.

"THE ELECTRICIAN" WIREMAN'S POCKET-BOOK.—"The Electrician" Company will shortly publish a valuable pocket-book for the use of those engaged in wiring work, both external and internal.

CARBONS FOR ALL ELECTRICAL PURPOSES.—By Francis Jehl. A work will shortly be published dealing fully with the manufacture of carbons for all electrical purposes. The book will illustrate the machinery and apparatus used in carbon manufacture on the Continent and in America, and will give the latest practice in this important subject.

THE ELECTRIC ARC.—By Mrs. Ayrton. This work will shortly be published, and will contain an historical sketch of the early experiments on the electric arc, as well as the important results of recent research.

SPECIAL NOTICE.

NOW READY.—Vol. XLI. of "The Electrician," bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

A complete set of the Second Series of "The Electrician" can now be supplied. These sets are very scarce, and early application should be made.

MUNICIPAL JACKS-OF-ALL-TRADES.

We commend to the careful consideration of everyone who is in any way interested in electrical manufactures and trading, in the United Kingdom, the following extract, which, with but trifling variation, is to be found in no less than *seventy* recent notices from local authorities intending to apply for statutory powers for electricity supply:—

To authorise the Council to manufacture, purchase, hire, sell, and to let all necessary lamps, accumulators, meters, dynamos, fittings, plant, machinery, apparatus and other matters or things required for the purposes of the Order, and to acquire, work and use patent rights for the generating, storing, collecting, distributing and measuring, or otherwise relating to the supply of electricity.

Could the full purport of this clause, and its broad issue if ever it is carried into operation, be realised by the electrical profession and industry of this country, we have little fear that they would supinely tolerate any such iniquitous encroachment on their just rights; but there is danger that the mischievous tendency of legislation in this direction may not be perceived, or, if perceived, its full influence may not be understood until it is too late to avert a catastrophe. Nor need we draw the line at the electrical profession and industry, for there is no indication that the mania for municipal trading in the future is to be confined to business of an electrical nature or anything of the character of public works. Whose turn it will be next we do not venture to predict; but the thin end of the wedge having been inserted, the entire bulk of that disruptive weapon can easily be driven in; the cloven hoof once revealed, the entire personality associated with that limb is likely enough soon to become apparent. Municipal tramways, lighting works, dynamo factories, wiring, fittings, heating and cooking departments, *et hoc genus omne*, may, indeed, be followed by a long series, including municipal bakeries, boot shops, newspaper offices, and all the odds and ends of trade by which mankind earns its daily bread. Such things, in fact, are even now claimed as the legitimate ground for municipal activity by many of the more advanced of the responsible representatives of this "progressive" school of socialism. In all respects,

Digitized by Google

therefore, in which the present tendency is prejudicial to the electrical profession, will that profession enlist the sympathy and claim the co-operation of every individual interested in any private industry or trading enterprise. Beyond that patent fact we ourselves are not concerned with the movement except in so far as it bears directly upon electrical affairs.

There are two principal aspects of municipal trading, as represented by the foregoing clause, from which it should be viewed with distrust, if not with alarm. The first is, that Municipalisation spells Monopoly. It has ever done so in the past, when the local authorities have succeeded in getting the upper hand; and from what it has revealed in the past we may infer its character in the future. For, the so-called principle which is held to justify the claim to monopoly is as applicable to every new form of municipal trading as it is to those to which it has been already held to apply. This principle is, that the ratepayers' capital and assets in municipal works must be protected from competition. If this is true of an electricity supply works, it is equally true of a municipal retail shop for the sale of any household commodity whatever. In support of this assertion, we may refer to a conference of the municipal authorities of Lancashire and Cheshire, held at the Manchester Town Hall on Tuesday last, for the purpose of organising opposition to two projected company undertakings which would create competition with local municipal electricity works. The Lord Mayor of Manchester said that the proposed schemes "trespassed" on the position of the various town authorities, and he thought it their duty to do their best "in the interest of the ratepayers" to secure their rejection in the House of Commons. But this intolerant attitude was capped by the position assumed by the Town Clerk of Liverpool, who argued that "municipalities ought to join and fight the matter out, not as a question of detail but of principle, and get it settled once for all that *when a Corporation had been authorised to spend money in any public undertaking it should be freed from all outside competition.*" And this enlightened pronunciamiento, breathing forth, as it does, the spirit of the middle ages, was received with acclamation. We may, therefore, regard it as an accepted canon of municipalisation, that all rate-aided undertakings are to be protected from outside rivalry and competition. Hence, local authorities having secured to themselves the right to "manufacture, purchase, hire, sell and to let" electrical plant, will next proceed to protect their business by enforcing their precious "monopoly"; or, in other words, independent company and private undertakings will have to come to an end. Surely it requires but little imagination to picture the disastrous results of this condition of affairs? Were it to operate throughout the land, in any considerable section of British industry, it would be nothing short of a national catastrophe.

The other chief aspect of municipal trading that calls for special notice is the financial basis upon which it is conducted. Municipal enterprise of this description is always in the nature of a subsidised undertaking, even where it is not a monopoly rigidly enforced by protective measures. Hence, where competition is not completely swept out of the sphere of influence of the little local demigods, their competitors must find themselves hopelessly handicapped through the special facilities the municipal traders possess for cheaper production and underselling. The security for capital offered by the majority of local government bodies is such that ample capital for municipal works can be attracted at a very low rate of interest, while the individual trader or joint-stock trading concern has to allocate a considerably larger percentage of the returns to this account. Financiers, by the way, will doubtless view with dismay the serious depreciating effect of extensive municipal trading upon the price of money, no less than the insecurity to capital itself, created by this unscrupulous competition. The normal rate of interest has steadily fallen for some time past; an era of municipal jacks-of-all-trades would probably lower the average rate to one half of its present value. Again, to revert to the main question, a local authority would always have the rates to draw upon in the event of its business showing a balance on the wrong side, whereas the ordinary trader might be ruined by such a contingency—an inequality of contest that would enable the rate-aided combatant absolutely to exterminate all rivalry by a short period of artificially depressed prices. And, in defence of the sacred rights of their municipal trading enterprises, local authorities would find ready excuse for killing off their rivals with such a weapon as this. The prospect wears no rosy hue, either for the independent trader or for the capitalist—or, *ipso facto*, for British labour.

Another new phase of municipalisation which has made its appearance recently in certain quarters, calls for notice on this occasion, as it bears upon the question of municipal trading. It used to be believed, and acted upon, that each local authority held sway over a well defined area and possessed no authority beyond that area. Even when the practice of municipalising works of various kinds came into vogue, local authorities were only permitted to conduct these undertakings within their own territories, and were debarred from encroaching upon the areas controlled by neighbouring authorities. An effort is now being made to have this barrier removed. A local authority is no longer to be a well-defined body, but is to become a nebulous thing capable of indefinite expansion and intermixture with similar nebulæ; at least, this will be the condition of affairs if Parliament should sanction the application for removal of existing restrictions to carrying on works beyond the normal area. Thus a town tramway system may reach out beyond the municipal boundaries and become a network of interurban lines, and, growing still more important, may ultimately assume the dimensions of an extensive system of railways, having no sort of natural relationship with the local authority controlling it. Endless complications must inevitably arise from the exercise of such powers. For example, Bradford may construct a municipal light railway to Leeds, and Leeds may want it extended to Harrogate, and Harrogate to Hull; and thus a through line from, say, Liverpool to Hull may eventually arise, with a through service of electric cars, similar to the interurban system of American traction companies. Whether this entire system be worked entirely by the Bradford Corporation, or whether each section be worked by separate authorities, the situation would be anomalous and absolutely "impossible." The same criticism applies to local authorities acquiring power to supply electric current, or to sell their municipal-made binding screws in the districts of other authorities. The movement would be confusion growing ever worse confounded.

In view of the extensive action of local authorities in this matter, as indicated by the great number of new notices embodying the clause set out at the commencement of this article, the Electrical Section of the London Chamber of Commerce, at a meeting presided over by Mr. Sidney Morse, recently decided to recommend joint action on the part of all similar organisations throughout the United Kingdom. We profoundly trust that, whether by this means, or in some other effective manner, the representatives of British trade and industry will succeed in stemming the destructive flood of socialism of which the above clause is but one of many indications.

REVIEWS.

Algebra Made Easy. Being a clear explanation of the Mathematical Formulæ found in Prof. Thompson's "Dynamo-Electric Machinery" and "Polyphase Electric Currents." By EDWIN J. HOUSTON and ARTHUR E. KENNELLY. (London: Swan Sonnenschein and Co. 1898.

The title appearing on the cover of this 100-page book is certainly misleading, and it is necessary to refer to the subtitle on the front page to ascertain the scope of the publication. An attempt is made to explain within these narrow limits, to a student who has not had the advantage of a school training in algebra, the meaning of the mathematical formulæ in Prof. Thompson's two books. "To handle and manipulate algebraic expressions, to solve equations and reduce them to their simplest forms, is," we are told in the introductory chapter, "an art attained only by study and practice, and with which the following pages do not deal. It has no essential part in the understanding of mathematical expressions." If any class of student attaches value to "understanding" mathematical expressions in this way, he will find the means to acquire this "Algebra Made Easy" in the book before us. Commencing on p. 5 with a definition of the common algebraical symbols, in 38 small pages of large type, he is brought to the end of a chapter on "Equations and Their Solutions." After a chapter on logarithms, "Trigonometry" is dealt with from pp. 56 to 71, and in 24 more pages differential and integral calculus is disposed of. It is hard to imagine that any reader could be benefited by a book of this sort, and it would be interesting to know whether Prof Thompson would not think it an "unnecessary or superfluous appendage" to his books. The last words in commas are quoted from the following passage in the introductory chapter, a passage hardly, we think, suited to the comprehension of a reader whose education has not been pushed far enough to include the simplest laws of algebra :—

> This symbolic language, which so largely pervades scientific technology, is the natural and beautiful language of exact quantitative expression. It is essentially a simple language, shorn, by long and wearisome evolution, of almost every vestige of unnecessary or superfluous appendage, and which, when properly enunciated, carries a meaning to the student as clear and perspicuous as its expression is brief and direct.

The Interpretation of Mathematical Formulæ.—By EDWIN J. HOUSTON and ARTHUR E. KENNELLY. (London: Swan Sonnenschein and Co. 1898.)

This book has a similar object to the above, but, not confining itself to those mathematical formulæ only which are used in Prof. Thompson's books, it has assumed about twice the size of "Algebra Made Easy." It does not stop short at integral calculus, but also deals with hyperbolic functions and determinants. The authors ingenuously remark in their preface :—"The authors, of course, do not claim, however, that those who have read this book thereby become expert mathematicians."

Specification. A Quarterly, No. 2, 1898. (London: The Proprietors of *The Builders' Journal and Architectural Record.*)

The chief characteristics distinguishing the second number of this quarterly from the first are a stiffer binding and substantial additions of matter bringing the book up to nearly double its former thickness. The section "Electrician" has been added to by the inclusion of short subsections on telephones, electric lifts and lightning conductors. Though there is much useful information to be gleaned out of this section by those already experienced, it is on the whole somewhat loosely and inaccurately written, and the hope we expressed in our notice of the first number has certainly not yet been adequately fulfilled as regards the revision of the electrical sections and the "Glossary of Terms." This latter still contains some highly interesting definitions. Under "Electric Bells" we learn that fuses are used in bell systems and "should be replaced once a year if not 'blown' (burnt by excess of current)." It is only fair to state that in spite of inaccuracies there is a mass of information regarding precedents and practice, which should prove of great assistance to engineers and architects capable of exercising due discrimination with their use of the suggestions and information given.

The Telephone System of the British Post Office. A Practical Handbook. By T. E. HERBERT. (London: Page and Pratt, Limited) 1898.)

This is a good and accurate technical description of the telephone systems employed by the Post Office in this country, preceded by a few chapters on first principles and on apparatus generally, and followed by a brief sketch of the methods of switching used by the National Telephone Co. The part descriptive of the Post Office system appears to have been brought completely up to date, and possibly we have no right to be disappointed that a forecast is not included in the shape of a detailed description of the methods of junction-transfer switching which are being introduced at the central trunk exchange in London. The volume will no doubt be found useful to the engineering staff both of the Post Office and of the National Telephone Co., and can be confidently recommended to them, although we do not expect the latter, or any of the London telephoning public, to credit the statement on p. 18, to the effect that the Ader receiver is but little used in England. The diagrams are not up to the usual standard of those in technical treatises, but probably an improvement in this respect and in the printing and paper would have considerably increased the cost of the publication. An alphabetical index would have been of use, and should not have been omitted.

ELECTROMAGNETIC THEORY.—CXI.*

BY OLIVER HEAVISIDE.

(Concluded from page 185.)

§ 447. So far O. P. M., Part 3. I regret that the condensation should tend to reduce it to the dry bones of mere formulæ. The original will not be published in Another Place before it is wanted. In the meantime I have only space left here for a few notes in connection with the preceding. They may be useful to investigators, as there are plenty of nuts to crack.

The formula (219) may be written

$$\frac{\pi}{\sin r\pi} = \sum \pm \frac{x^r}{r} = u. \tag{253}$$

The companion formula is

$$\pi \cot r\pi \pm \lambda = \sum \frac{x^r}{r} = v, \tag{254}$$

and possesses several points of interest. Just as u comes from the generalised ϵ^z, so does v come from the generalised ϵ^{-z}. Thus,

$$\epsilon^{\Delta}1 = \sum \frac{\Delta^r}{\lfloor r}1 = \sum \frac{x^{-r}}{\lfloor r \lfloor -r} = \sum \frac{x^r}{r}\frac{\sin r\pi}{\pi}, \tag{255}$$

$$\epsilon^{-\Delta}1 \,||\, \sum \frac{\Delta^r}{\lfloor r}\frac{1}{\cos r\pi} \,||\, \sum \frac{x^r}{r}\frac{\tan r\pi}{\pi}. \tag{256}$$

Now (254) is exact when $x=1$, without λ. But when x is not 1, the functions u and v differ in behaviour. The first is continuous through $x=1$, the second is discontinuous. That is, there is a jump up through the amount λ when x is just above 1, and a jump down to the same extent when x is just below 1, λ being about 1·895, as found below. Why there should be a discontinuity in v, though not in u, at $x=1$, may be understood by considering that $\epsilon^{\Delta}\Delta 1$ is an impulse at $x=-1$, and $\epsilon^{-\Delta}\Delta 1$ an impulse at $x=+1$. So in the latter case integration produces a jump.

Or we may differentiate v to x. We get $0=\sum x^r$. This means that $\sum x^r$ is an impulsive function. It is ∞ at $x=1$. Note also that in the theory of convergent functions the expression $\sum z^r$, z being complex, plays the part of an impulsive function at the point $z=1$, although, of course, function-theorists would not, I think, admit that it had, by itself, any particular meaning.

By differentiation to r, the v formula makes

$$-\frac{\pi^2}{\sin^2 r\pi} = (\pi \cot r\pi \pm \lambda)\log x - \sum \frac{x^r}{r^2}, \tag{257}$$

* This series of Articles is a portion of Vol. II. Mr. Heaviside's work on "Electromagnetic Theory." All rights of reproduction are reserved.

Digitized by Google

and other formulæ may be derived. Perhaps the most interesting particular case of v is when $r=0$. Then there is an infinite term $x^s/0$ on the right side of (254). Deduct it from the left side. The result is

$$-\log x \pm \lambda = x + \tfrac{1}{2}x^2 + \tfrac{1}{3}x^3 + \ldots - x^{-1} - \tfrac{1}{2}x^{-2} - \ldots. \quad (258)$$

Remembering the potency of λ, this leads to

$$w = x + \tfrac{1}{2}x^2 + \tfrac{1}{3}x^{-3} + \ldots = \lambda - \log(x-1), \quad (x>1), \quad (259)$$

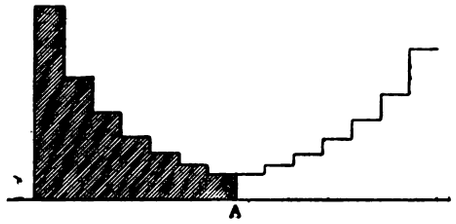
$$\text{or} = -\log(1-x), \quad (x<1). \quad (260)$$

This w function is infinite at $x=1$; beyond that it changes from $-\log(1-x)$ to $\log \mu(x-1)$, $^{-1}$ where μ is a constant (about 6·653). It is then continuously divergent. When x is <-1 it is alternatingly divergent.

To show λ by itself, we have

$$\pm\lambda = 2(x + \tfrac{1}{3}x^3 + \tfrac{1}{5}x^5 + \ldots - x^{-1} - \tfrac{1}{3}x^{-3} - \tfrac{1}{5}x^{-5} - \ldots). \quad (261)$$

Numerical examination of various cases of the cot and log formula all lead to about the same value of λ when done roughly, usually from 1·8 to 2. But to find it more closely, special care must be taken. Some of the derived formulæ are much more convergent than the primitive; but this does not help as regards close estimation of λ, because the error becomes multiplied in another way. To find λ pretty closely, I used the w formula (259), with x between 1 and 2. The results are very regular when attention is paid to certain points. The error, if estimated by the size of the l.c.t., would be large unless a value of x so little greater than 1 were used that the labour became prohibitive. But there are certain considerations allowing of closer work with less labour. Thus, in the series $w = x + \frac{1}{2}x^2 + \ldots$, give x a value between 1 and 2, say 1·1, such that there are two equal bottom terms. Representing the series diagrammatically thus, we have to find the



lowest point, when regarded as a continuous curve. If quite symmetrical, the lowest point would be at A, and the shaded area would represent the value of the series. But there never is symmetry, so A is not quite, though nearly, right. In this way, choosing values of x producing two equal bottom terms, excellent results are obtainable by stopping at the end of the first of the two.

But if x is such that there is but one l.c.t., the results will be staggery if we always count the full l.c.t., or always one-half of it, &c. We should plainly count a portion only of the l.c.t. of such size as harmonises with the case of two equal bottom terms. Now to get the nth term to equal the $(n+1)^{\text{th}}$ when $x = 1 + m^{-1}$, requires $n = m$. Use this rule whether m be integral or fractional. For example, if $x = 1{\cdot}8$, $n = 3\frac{1}{3}$, count three terms and $\frac{1}{3}$ of the next. Then regular results arise, as may be seen by the following:—

x	n	λ	l.c.t.
2	1	2	
1·5	2	1·932	
1·4	2·5	1·921	0·916
1·3	3·33	1·9114	0·714
1·2	5	1·9026	0·4976
1·1	10	1·8974	0·2596
1·05	20	1·8953	0·1362
1·025	40	1·89520	0·0671
1·01	100	1·89518	0·0270

Observe that very large variation in the size of the l.c.t. makes little difference in the calculated value of λ, and that the last three results agree to four figures. It would seem that 1·895 is correct as far as written. But what it means (in terms of π or other constants) I do not know.

In the algebraical theory λ would not be a real constant, but an indeterminate imaginary. Thus

$$\text{if} \quad y = x - \tfrac{1}{2}x^2 + \tfrac{1}{3}x^3 - \ldots, \quad \text{then} \quad \epsilon^y = 1 + x \quad (262)$$

is an identity, or $y = \log(1+x)$. This can be interpreted for any value of x, by using $\epsilon^{in\pi} = -1$, n being an odd number; or $\log(-1) = in\pi$. In accordance with this, $w = -\log(1-x)$ for any value of x, which makes the superinfinite w (when $x>1$) be complex to suit the algebra, whereas the divergent series w is real.

There is a similar conflict in the cot formula. By squaring the series u and v, it can be shown that

$$u^2_r = \pi \cot r\pi (v_r - v_{r+\frac{1}{2}}), \quad (263)$$

$$v^2_r = \pi \cot r\pi (v_r + v_{r+\frac{1}{2}}). \quad (264)$$

The formula for u is satisfied, but that for v, containing λ, will not do. If, however, we put $\lambda = \pm i\pi$, then we harmonise the algebra at the expense of making the series v be complex when x is real.

The generalised ϵ^x and ϵ^{-x} formulæ show a conflict also. Thus, by squaring,

$$\left(\Sigma \frac{x^r}{\lfloor r}\right)^2 = \Sigma x^{2r}\left(\frac{1}{\lfloor r \lfloor r} + \frac{2}{\lfloor r+1 \lfloor r-1} + \frac{2}{\lfloor r+2 \lfloor r-2} + \ldots\right)$$
$$+ \Sigma x^{2r+1}\left(\frac{2}{\lfloor r \lfloor r+1} + \frac{2}{\lfloor r-1 \lfloor r+2} + \ldots\right)$$
$$= \Sigma \frac{x^{2r}2^{2r}}{\lfloor 2r} + \Sigma \frac{x^{2r+1}2^{2r+1}}{\lfloor 2r+1} = \Sigma \frac{(2x)^r}{\lfloor r}; \quad (265)$$

i.e., $(\epsilon^x)^2 = \epsilon^{2x}$, with the generalised series. In a similar manner, we can show that

$$\left(\Sigma \pm \frac{x^r}{\lfloor r}\right)^2 = \Sigma \pm \frac{(2x)^r}{\lfloor r}. \quad (266)$$

This would be satisfied by $\epsilon^{-x} = \Sigma \pm x^r g(r)$. But it is not true, save when x is integral. The effective meaning of the series is not ϵ^{-x}, but $\epsilon^{-x}\cos r\pi$. I do not explain, but take things as I find them.

The w series above runs up to ∞ at $x=1$, and then runs down again on the other side, with a constant multiplier introduced. But there is not necessarily a change of this kind in passing through infinity. For instance,

$$U = 1 + \tfrac{1}{2}x(1 + \tfrac{3}{4}x(1 + \tfrac{5}{6}x(1 + \tfrac{7}{8}x(\ldots \quad (267)$$

represents $(1-x)^{-\frac{1}{2}}$ when $x<1$. It is convergent down to $x=-1$, and then alternatingly divergent and calculable. At $x=1$ it is infinite. But it is directly divergent and calculable when $x>1$, and seems to represent $(x-1)^{-\frac{1}{2}}$. Here there is conflict with the algebra of i.

But the series

$$V = 1 - \tfrac{1}{2}x(1 + \tfrac{1}{4}x(1 + \tfrac{3}{6}x(1 + \tfrac{5}{8}x(\ldots, \quad (268)$$

which represents $(1-x)^{\frac{1}{2}}$, and is alternatingly divergent when $x<-1$, passes through zero when $x=1$, and then becomes directly divergent. Considered as a function satisfying a differential equation, we should say it then represents $c(x-1)^{\frac{1}{2}}$ where c is a real constant. But c is not 1, as in the last case, but is $-\frac{1}{2}$, by rough calculation. The negativity can be easily explained, for $V = (1-x)U$ by algebra, and when U is $(x-1)^{-\frac{1}{2}}$, V is negative. A reason can also be given why the algebraical relation $V = (1-x)U$ is numerically violated. For though U and xU have the same point of convergence when $x>1$, yet when they are united to make the V series, the point of convergence is shifted to quite another place. But I do not see why the factor should be $\frac{1}{2}$, if that be the true value. It is remarkable that the divergent Bessel functions should be more understandable, both algebraically and numerically, than elementary cases of Newton's binomial theorem.

§ 448. The following electrical method of constructing formulæ for comparison is worthy of attention. If two electrical combinations whose resistance operators are Z_1 and Z_2 be put in sequence, and an impressed voltage e act at their junction, the current there is $C = e(Z_1 + Z_2)^{-1}$, and the voltage on the Z_2 side is

$$V = Z_2 C = \frac{e}{1 + Z_1/Z_2}. \quad (269)$$

Taking various forms of Z_1 and Z_2 we may obtain interesting results by different ways of algebrisation. For instance, there are two ways of expansion of the operator $(1 + Z_1/Z_2)^{-1}$ by division. That either of the series of operations should give V correctly is remarkable. It will do so if the result is

Digitized by Google

convergent. That the other way should give an equivalent result is much more remarkable. This occurs sometimes. But it usually happens that the divergent result is not the full equivalent of the convergent result. Interesting generalised series connect them.

Say $Z_1/Z_2 = ap^{\frac{1}{2}}$, and $e=1$, starting at $t=0$. Denote the convergent result by u, and the divergent by v. Then

$$u = a^{-1}p^{-\frac{1}{2}} - a^{-2}p^{-1} + a^{-3}p^{-1\frac{1}{2}} - a^{-4}p^{-2} + \ldots$$
$$= \left(\frac{t^{\frac{1}{2}}}{a\lfloor\frac{1}{2}} + \frac{t^{\frac{3}{2}}}{a^3\lfloor\frac{3}{2}} + \ldots\right) - \left(\frac{t}{a^2\lfloor 1} + \frac{t^2}{a^4\lfloor 2} + \ldots\right). \quad (270)$$

This satisfies (269), and is right initially, and is convergent. It is not immediately evident what V rises to finally, though we know it should be 1. The other way makes

$$v = 1 - ap^{\frac{1}{2}} + a^2p - a^3p^{1\frac{1}{2}} + a^4p^2 - \ldots$$
$$= 1 - \left(\frac{at^{-\frac{1}{2}}}{\lfloor -\frac{1}{2}} + \frac{a^3t^{-1\frac{1}{2}}}{\lfloor -1\frac{1}{2}} + \ldots\right). \quad (271)$$

This also satisfies (269); it is not evident what it means initially, but it is 1 when $t=\infty$. Here u and v are equivalent when a is +. Equating them, we obtain the generalised ϵ^{t/a^2}. But u and v are not equivalent when a is −. $V=u$ is the solution then, but not $V=v$. To see this put $a=-b$ and let b be +. Then use the generalised ϵ^{t/b^2} to the first part of u. Let u become w. It is

$$w = 1 - 2\epsilon^{t/b^2} + \left(\frac{bt^{-\frac{1}{2}}}{\lfloor -\frac{1}{2}} + \frac{b^3t^{-1\frac{1}{2}}}{\lfloor -1\frac{1}{2}} + \ldots\right). \quad (272)$$

This is the solution when a is negative. Comparing with v, we see that in passing from positive to negative a, the extra term $-2\epsilon^{t/a^2}$ is added.

The electrical interpretation is interesting. *See* § 242. Let a cable (having resistance and permittance only) of infinite length be earthed at $x=0$ through a resistance, and e be inserted there. Then u or v show the rise of V at the beginning of the cable from 0 to 1, when the terminal resistance is positive, and u or w show the rise of V from 0 to $-\infty$ when the resistance is negative. When a is reduced to zero, the rise from 0 to 1 takes place instantly. When b positive is reduced to zero, the rise from 0 to $-\infty$ takes place instantly. That is, if we had a negative resistance, even of infinitesimal amount, the finite voltage e would generate an infinite voltage instantly under the circumstances stated.

As a second case, let $Z_1/Z_2 = ap^{-\frac{1}{2}}$. Then

$$u = 1 - ap^{-\frac{1}{2}} + a^2p^{-1} - a^3p^{-1\frac{1}{2}} + \ldots$$
$$= \epsilon^{a^2t} - \left(\frac{at^{\frac{1}{2}}}{\lfloor\frac{1}{2}} + \frac{a^3t^{1\frac{1}{2}}}{\lfloor 1\frac{1}{2}} + \ldots\right), \quad (273)$$

$$v = a^{-1}p^{\frac{1}{2}} - a^{-2}p + a^{-3}p^{1\frac{1}{2}} - a^{-4}p^2 + \ldots$$
$$= \frac{1}{at^{\frac{1}{2}}\lfloor -\frac{1}{2}} + \frac{1}{a^3t^{1\frac{1}{2}}\lfloor -1\frac{1}{2}} + \ldots. \quad (274)$$

Here u and v are equivalent again when a is +, as we see by equating them. V falls from 1 to 0. But when a is $-b$, and b is +, the result is

$$w = 2\epsilon^{b^2t} - \left(\frac{1}{bt^{\frac{1}{2}}\lfloor -\frac{1}{2}} + \ldots\right). \quad (275)$$

This comes from u by the generalised exponential. V now rises from 1 to ∞. It is a terminal condenser, instead of a resistance, that is concerned. *See* § 248.

Thirdly, let $Z_1/Z_2 = ap^{1\frac{1}{2}}$. Then

$$u = a^{-1}p^{-1\frac{1}{2}} - a^{-2}p^{-3} + a^{-3}p^{-4\frac{1}{2}} - a^{-4}p^{-6} + \ldots \quad (276)$$

is the convergent solution, true whether a is + or −. But the other result dividing the other way, viz.,

$$v = 1 - ap^{1\frac{1}{2}} + a^2p^3 - a^3p^{4\frac{1}{2}} + a^4p^6 - \ldots, \quad (277)$$

is not equivalent to u whether a be + or −. The reason is this. Let

$$X = \ldots + 1 + bp^{1\frac{1}{2}} + b^2p^3 + b^3p^{4\frac{1}{2}} + \ldots, \quad (278)$$

the series being complete both ways. What is its value? Now

$$2\epsilon^t = \ldots + 1 + p^{\frac{1}{2}} + p + p^{1\frac{1}{2}} + \ldots, \quad (279)$$

and I find that the sum of every third term beginning anywhere equals $\frac{1}{3}$ of the total. Therefore $X = \frac{2}{3}\epsilon^{t/c}$, if $c = b^{\frac{1}{2}}$, and b is +, and the equivalent solutions are

$$u = -(b^{-1}p^{-1\frac{1}{2}} + b^{-2}p^{-3} + b^{-3}p^{-4\frac{1}{2}} + \ldots), \quad (280)$$

$$w = -\tfrac{2}{3}\epsilon^{t/c} + 1 + bp^{1\frac{1}{2}} + b^2p^{4\frac{1}{2}} + \ldots, \quad (281)$$

when b is +. Here by p^{-n} is to be understood $t^n/\lfloor n$, to save useless work.

But when a is +,

$$u = (a^{-1}p^{-1\frac{1}{2}} + a^{-3}p^{-4\frac{1}{2}} + \ldots) - (a^{-2}p^{-3} + a^{-4}p^{-6} + \ldots) \quad (282)$$
$$= \tfrac{2}{3}\epsilon^{t/c} - (1 + ap^{1\frac{1}{2}} + a^3p^{4\frac{1}{2}} + \ldots) - 2(a^{-2}p^{-3} + a^{-4}p^{-6} + \ldots). \quad (283)$$

Here

$$1 + a^{-2}p^{-3} + a^{-4}p^{-6} + \ldots = \tfrac{1}{3}\{\epsilon^{t/c} + 2\epsilon^{-t/2c}\cos(t/c)(\tfrac{3}{4})^{\frac{1}{2}}\}, \quad (284)$$

so u is transformed to

$$u = w = 1 - (ap^{1\frac{1}{2}} + a^3p^{4\frac{1}{2}} + \ldots) - \tfrac{4}{3}\epsilon^{-t/2c}\cos(t/c)(\tfrac{3}{4})^{\frac{1}{2}}, \quad (285)$$

when a is +. This explains the result (86), § 244, relating to a terminal inductance.

§ 449. The above three cases illustrate the general theory, which may be just sketched here. Let

$$U = \frac{1}{1-bp^r} = -(b^{-1}p^{-r} + b^{-2}p^{-2r} + b^{-3}p^{-3r} + \ldots). \quad (286)$$

This is the convergent solution when r is +. It is not necessary to consider r to be −, because the theory is quite similar. To transform U to the equivalent W when b is +, let

$$X = \ldots + 1 + bp^r + b^2p^{2r} + b^3p^{3r} + \ldots, \quad (287)$$

the series to be complete. Then

$$W = -X + 1 + bp^r + b^2p^{2r} + b^3p^{3r} + \ldots \quad (288)$$

is the required result.

When r is the reciprocal of any integer, say n^{-1},

$$X = \frac{1}{r}\epsilon^{t/c}, \quad (289)$$

where $c = b^{1/r}$, because of the generalised ϵ^t formula. But when b is negative, $X=0$. For when n is even, $\frac{1}{2}n$ generalised ϵ^t expressions are cancelled by the other $\frac{1}{2}n$. And when n is odd, the generalised ϵ^{-t} expression occurring n times equally annihilates the result. Thus, $n=5$, omitting the constant,

$$X = \epsilon^{-t}(1 - \cos\tfrac{1}{5}\pi + \cos\tfrac{2}{5}\pi - \cos\tfrac{3}{5}\pi + \cos\tfrac{4}{5}\pi) = 0. \quad (290)$$

It follows that in the physical case, when a is +, both the solutions, convergent and divergent, are obtained by division, as in the cases $r=\frac{1}{2}$ and $-\frac{1}{2}$ given above, whilst when a is −, there is an extra term, − X. In any case the matter is resolved into the evaluation of X. Putting $c=1$ for ease,

$$X = \ldots + 1 + p^r + p^{2r} + \ldots = r^{-1}\epsilon^t \quad (291)$$

is not only true for $r=1$, $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, &c.; but also for their doubles, except when it makes $r=2$. The generalised ϵ^{-t} formula shows the validity of this doubling. But when r is an integer, then

$$X = 1 + p^{-n} + p^{-2n} + \ldots = n^{-1}(\epsilon^t + \epsilon^{ct} + \epsilon^{c^2t} + \ldots), \quad (292)$$

where 1, c, c^2, &c., are the $n\,n^{th}$ roots of 1. So $X = r^{-1}\epsilon^t$ is not true for r integral, save 1, and there may be special peculiarities when $r>1$ and fractional, though it is true when $r=1\frac{1}{2}$. But continuity would seem to show that it is true from $r=0$ to $r=1$ generally. The following refers to $r=m/n$, m being a smaller integer than n. A special case will be easier to follow. Say $r=\frac{4}{5}$, then

$$X = (1 + p^{\frac{1}{5}} + p^{\frac{2}{5}} + p^{\frac{3}{5}} + p^{\frac{4}{5}})\ (\ldots + 1 + p^4 + p^8 + \ldots)$$
$$= (1 + p^{\frac{1}{5}} + p^{\frac{2}{5}} + p^{\frac{3}{5}} + p^{\frac{4}{5}})\tfrac{1}{4}(\epsilon^t + \epsilon^{it} + \epsilon^{-t} + \epsilon^{-it}). \quad (293)$$

Here $p^r\epsilon^t = \epsilon^t$; $p^r\epsilon^{-t} = \epsilon^{-t}\cos r\pi$, $p^r\cos t = \cos(t + \frac{1}{2}r\pi)$, (294)

so we get X = sum of five correct real formulæ, and this sum comes to $\frac{5}{4}\epsilon^t$, as required.

If imaginary parts cancel one another at the end, the imaginary may be employed throughout. Thus, $r=\frac{3}{4}$.

$$X = (1 + p^{\frac{1}{4}} + p^{\frac{2}{4}} + p^{\frac{3}{4}})\,(\ldots + 1 + p^3 + p^6 + \ldots)$$
$$= (1 + p^{\frac{3}{4}} + p^{\frac{2}{4}} + p^{\frac{1}{4}})\,\tfrac{1}{3}\,(\epsilon^t + \epsilon^{ct} + \epsilon^{c^2t}), \quad (295)$$

where $c = i^{1\frac{1}{2}}$. Now take $p^r\epsilon^{ct} = c^r\epsilon^{ct}$. Then

$$X = \tfrac{4}{3}\epsilon^t + \tfrac{1}{3}(1 + i + i^2 + i^3)\epsilon^{ct} + \tfrac{1}{3}(1 + i^2 + i^4 + i^6)\epsilon^{c^2t}, \quad (296)$$

which is $\frac{4}{3}\epsilon^t$, as required. Numerical results are good. This process goes when $r=m/n$. But the individual results, when complex, are not true. *E.g.*, $p^r\epsilon^{i^2t}$ is not $i^{2r}\epsilon^{-t}$, but only the real part thereof. There is more to be said on this subject, and I have no doubt a good deal more will be said when proper mathematicians will thoroughly explore divergent series for physical purposes. But this volume is now full up.

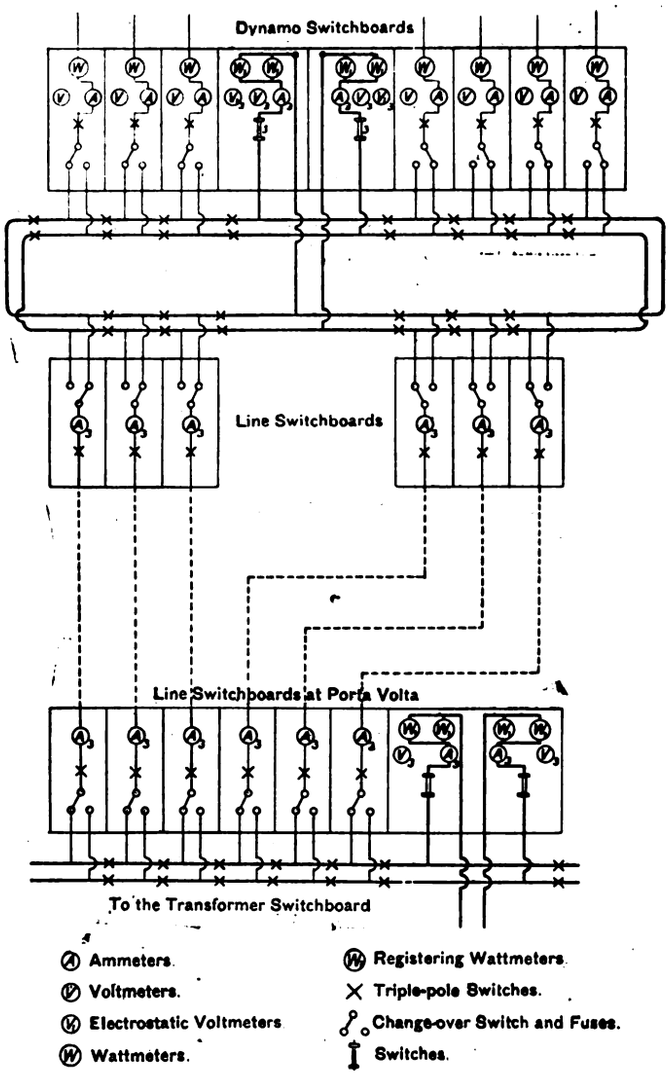
THE WATER-POWER INSTALLATION AT PADERNO.*

BY G. SEMENZA.

(TRANSLATED BY JOHN R. DICK, B.SC.)

(*Concluded from page 365.*)

One of the most remarkable parts of the plant is the switchboards. The great importance given to switchboards is of quite recent date, and arises from the latest experience in materials. In the first stations where large currents at high pressure were used, no greater importance was given to the switchboards than to those for ordinary lighting stations. But the numerous difficulties that arose gradually proved that in such installations the switchboards represent one of the most delicate parts of the whole plant. Consequently they ought



Arrangements of the Switchboards for the Electrical Transmission from Paderno to Milan.

to be designed very carefully, without sparing expense, and provided with plenty of room. The switchboard at Paderno, built on these lines, has an area of about 17 sq. ft., and is fixed in a large opening in the middle of the wall of the dynamo room. The dynamo instruments are placed on a gallery 9ft. 6in. above the floor, while those for the line are placed on the other side of the switchboard room. The dynamo switchboard is divided into nine panels, of which seven belong to the seven alternators, while the other two are used for the 'bus bars and are fixed in the centre of the board.

Each of the panels of the dynamo board carries the following apparatus and instruments:—one double-pole high-tension switch, three fuses, one change-over switch, one regulator for the exciting current, one regular for the exciter field, one switchboard transformer, one volt meter, one ammeter, one watt meter for the alternating current, one ammeter for the exciting current, one voltmeter and synchronising lamp.

These are more or less the apparatus and instruments which are found on all the panels; some, however, merit special notice. With regard to the switch, it may be remarked that all currents at a low voltage can be broken without difficulty because the pressure is not sufficient to maintain an arc when the two contacts of the switch are at a little distance from each other. Small currents at very high voltages can also be broken without special apparatus, because up to a certain limit they lack the necessary energy to overcome the resistance of the air. But when both pressure and current are large the case is different. With 8,500 volts and 150 amperes one gets an arc which may exceed 8ft. in length, and with 8,000 volts and 80 amperes an arc which exceeds 5ft. When those enormous arcs are developed between two parts of a switchboard, they are carried upwards by the action of the hot air, and pass through any conductors they may encounter, melting metals, smashing insulators and burning wood and rubber.

The length an arc may assume depends, first of all, on the nature of the dielectric in which it occurs. It depends, in the second place, on the material of which the electrodes are composed; thus, if the electrodes are of copper we get a much longer arc than if they are of carbon, because the copper vapour, which volatilises and burns, forms a path of higher conductivity than that formed from particles of carbon. And here we find an explanation of the efficacy of quick break switches. With a quick break switch of the type of the General Electric Co. a current of 70 amperes at 3,600 volts is easily broken, but if it is done slowly with the same switch the arc cannot be extinguished, because, with the increase in rapidity of movement, the formation of copper vapour is rendered much less. The principle of a quick break in oil is employed in the construction of the high-pressure switches at Paderno.

Safety fuses present an analogous problem, but, fortunately, the solution is very safe and simple. The fuses made by the firm of Brown-Boveri and Co. have given such a perfect action at 5,000 volts as to justify considerable confidence in their action at higher pressures. The fuse wire is stretched out in an open tube of composition or of porcelain. When the fuse goes the arc thus formed instantaneously expands the air contained in the tube, and causes a kind of explosion which extinguishes the arc. On the left of the board there is a change-over switch, whose object we will now describe. The whole of the installation, commencing with the switchboards of Paderno going step by step to Porta Volta and Santa Radegonda, has been designed so that there may always be the possibility of splitting up the supply into two distinct parts. The 'bus bars are are in duplicate, and each dynamo may be connected up to either of the two.

Thus the lines, as well as the transformers at Milan, the dynamos at Porta Volta, &c., can be separated from each other. This has been designed so as to keep the two supplies distinct, should one supply have special requirements, or be a source of disturbance to the other. Our own experience and that of others on the supplying in parallel of motors, lighting and traction leads us to believe that such separation would be unnecessary. In any case, however, the measure is prudent and will render the supply more secure.

The wattmeter on the switchboard of each dynamo was introduced more with the idea of giving a true relative indication of the load of each alternator than to give an absolute reading, because when several alternators are running in parallel, the ammeters give very little indication of the true load on the machines, this being affected by the difference of phase. The electrostatic voltmeters placed on the main switchboard measure the pressure at Milan. Three pilot wires are fixed on the posts under the principal conductors, and connect the voltmeters directly with the secondary circuit at 150 volts placed in the station of Porta Volta. These are of very great importance because it is according to their readings that the pressure at the station is regulated.

* Lecture given before the Milan section of the Associazione Elettrotecnica Italiana

Digitized by Google

Behind the row of dynamo switchboards are fixed the line switchboards. The lines are six in number, and each one has its own switchboard with change over switch, fuses and ammeters. All the switchboards are in general accessible where possible; each section may be completely separated from the others which are live, so that a man can work on them or clean them with perfect safety. They are all made of iron, porcelain and marble, and no combustible material is employed. The connections are all made of rigid bars and the *tout ensemble* is symmetrical, simple and mechanical.

The lines run from the switchboards into a room above where the lightning arresters are placed; from thence they pass through suitable openings placed in the back wall of the room to the first post. As we have already said, the number of wires in the line will be 18. A high-tension line of this description intended for an important public supply, like that of Milan, had to be designed with special care and precautions to avoid breakdowns; it was not only necessary to have the line well made, but to have a line which could be repaired without interrupting the supply. From the station of Paderno and that of Porto Volta runs a double row of posts; each row carries nine wires, and is at a distance of 6ft. 6in. from the other. When it is necessary, from any reason whatsoever, to work on one of the lines, the whole of the section to which it belongs can be cut out of circuit, and the supply carried by the other half alone. At times of heavy load in such cases there will be a greater drop of pressure, but this has been provided for by the possibility of increasing the pressure of the alternators to 15,000 volts.

In the early alternate-current installations the line was one of the chief sources of failure, and that because not even a remote idea was entertained of the importance of the effects of mutual and self-induction. It is curious that although academically the case had been worked out some time before, yet among the lines proposed by the different manufacturing firms there were solutions perfectly diverse and contradictory. Now all this part is well enough known, so that it is possible to proceed with perfect safety. It is recognised that, in order to have a weak, small inductance, the wires must be of small diameter and far apart, necessitating, in the case of heavy currents, a considerable number of wires. Then there is another very important point, and that is, when the wires are numerous they must be arranged in such a manner that the effects of induction are equal on all. If not, there will be a tendency to produce idle currents between the wires belonging to the same branch of the system.

The theoretically perfect arrangement of a number of conductors carrying three-phase currents would be that in which each conductor was placed in the same condition of induction with respect to the others. A cross-section of the arrangement would show all the wires placed at equal distances on a circle. This form of grouping the conductors, although possible to realise, is not very practical, especially if the number of wires is great. The form which, after the circle, gives the smallest mutual induction between the different wires of the same branch is that represented in the figure, in which the wires are arranged in the form of a triangle. This is the arrangement actually adopted on the Paderno line. The wires are 0·354in. diameter, and the distance between the nearest is 2ft. They are of electrolytic copper of 98 per cent. conductivity, and are fixed up in such a way as to have, with a span of 197ft., a dip which varies from 2ft. in the hardest winter to 4ft. in the hottest summer.

In lines for alternating current it is necessary to consider the loss of energy as well as the drop of pressure. The loss of energy is the product of the resistance by the square of the current, and will be about 9 per cent. at full load when the power factor is 80 per cent. The expression for the drop of pressure is somewhat more complex. The special case was studied by the late Prof. Ferraris, and the resulting calculation is of the highest interest. In this calculation the branch of the three-phase system to which each wire belongs must be taken into account, because the effect of mutual induction is a function of the positions of all the nine wires, the relative distances, and the currents which flow through them. The drop of pressure is a function of this coefficient of mutual induction, the ohmic resistance of the wire, the current, and lastly the difference of phase caused by an inductive load. All these quantities properly combined give as a result the drop of pressure which in our case is about 12·5 per cent., while the loss of energy is only 9 per cent.

This is one of the first lines in which entirely metallic masts are used. Although the fall of one wire or the breaking of an insulator may cause a dead earth, their mechanical superiority is undoubtedly of great value. Besides, it is not at all easy to find wooden posts of sufficient length, and the construction of mixed posts is not a satisfactory solution; hence, it was preferable to take greater care in the design of the insulators, and to employ posts entirely of iron. The post is made of light lattice work. Each post weighs about 9cwt., and is embedded in a mass of concrete. Where there are curves along the route two posts are joined together to form a St. Andrew's cross. The insulator carrier is very strong, and has a light steel spindle in order to prevent the accumulation of snow. Under the conditions to which our line is subject, the insulator is a detail of the highest importance, and is of special design. There are two types which seem to meet the requirements of the case—the one the American bell type, which has an internal core of glass or hard porcelain; the other the multiple umbrella type, made entirely of porcelain.

The idea of the American type is, by means of the glass or hard porcelain part, to offer a high resistance to perforation by electrical discharges, while the external portion of enamelled porcelain presents a long path for surface leakage and for direct discharges through the air. In the multiple umbrella type the first object is accomplished by increasing the thickness of the porcelain in proximity to the head, the second by the large development of the leakage surface. The available experience in materials not being very extensive, it was decided to use one of the types on one line and the other on the other, Both are constructed by the Societa Ceramica Richard-Ginori. The line does not follow the same route as the roads, but crosses the country in a direction very nearly that of a straight line, and the angles which it makes, either to avoid houses or other obstacles, do not in any case exceed 8deg. or 4deg. Larger angles are used for crossing the railway lines and water courses, and also where it enters Milan. If it had followed the roads the work of inspection would have been easier, but it would have increased the angles and lengthened the route.

The Edison Company pays the proprietor a price per yard of route which covers the wayleave for wires and posts, the repairs of damages during erection in a strip of land 10ft. wide, and the damages incurred in inspecting and repairing the line during a period of 30 years. The Edison Company, in return, possesses the right to pass along this strip of land with vehicles and carts as often as may be necessary. The work of inspection is thus quite an easy matter.

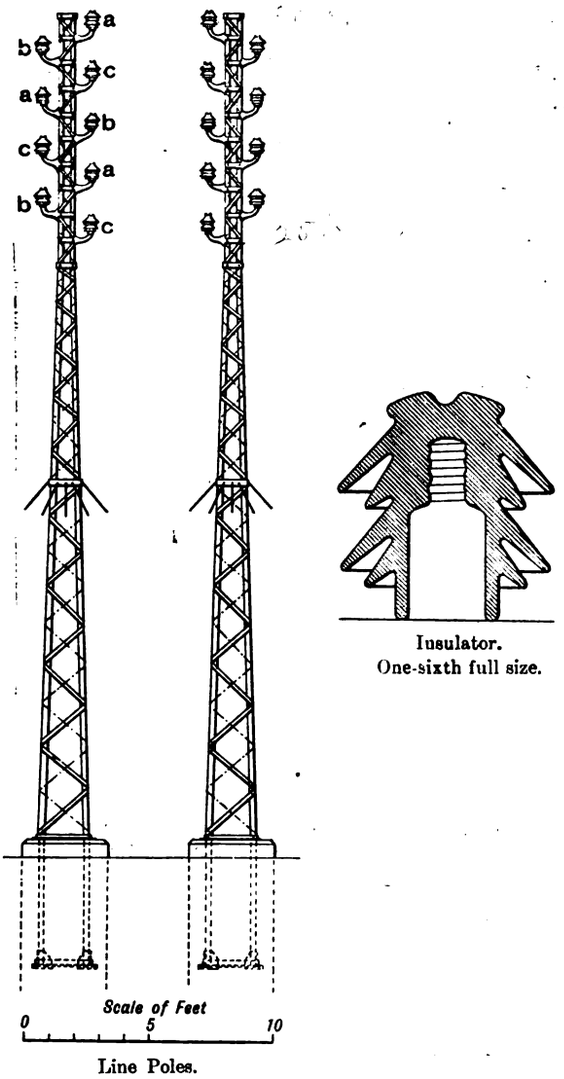
One of the most delicate points in connection with high-tension lines is the protection against atmospheric discharges. I shall endeavour now to give a *résumé* of the points on which common knowledge is agreed with regard to this question, premising that it deals rather with hypothesis and assumptions than with ascertained facts, and that, accordingly, I shall use language which is empirical rather than scientific.

It appears that the lightning discharges affect the line chiefly in the three following ways:—(1) The discharge between a cloud and the earth may pass through a greater or less length of the wires; (2) A discharge between two clouds may induce a disturbance in the wires; (3) A cloud overhanging the wires may induce a charge at a high potential in them.

In the first case the charge may or may not be oscillatory. In the second and third, the general opinion is that it is always oscillatory. Whether it is so or not is of the very highest importance, because its nature and effects are completely different in the two cases. Any discharge, whether oscillatory or not, always encounters an impedance in the conductors of a greater amount than the mere ohmic resistance, but if the discharge has the form of a single flow of energy it will encounter a diminishing impedance in the con-

Digitized by Google

ductor, and after a few instants it will flow like an ordinary current. In the case, however, where it is oscillatory, with a frequency of, perhaps, millions of cycles per second, the ohmic resistance becomes a negligible quantity in comparison with the enormous inductance which the circuit presents. The result is that an oscillating discharge, rather than flow along a single turn of copper wire, will jump across an air-gap of several inches, because the impedance of one turn of wire is such that the difference of potential at its extremities may reach very high values. It is obvious at once that the effects of the two kinds of discharge will be distinctly different. A discharge striking the wire, and which is not oscillatory, will tend to follow the line until it comes to a point where the insulation to earth is weak. If this point is an air space there will be a spark; if it is an insulator the latter will be perforated. An oscillatory discharge, on the other hand, will seek the least inductive path to earth, and will jump over



Line Poles.

Insulator.
One-sixth full size.

large air spaces rather than pass through a long wire or a coil.

Sometimes, during thunderstorms, lightning discharges will jump directly to earth through strata of air four or five yards in thickness rather than follow the wires to their extremities, where air spaces of only a few inches will be found.

Generally speaking, then, it is not difficult to prevent the discharge from reaching the machines and transformers, especially if it is oscillatory. The chief trouble arises afterwards. It nearly always happens that the different wires of the line are struck simultaneously, and the two sparks, the lightning conductors and the earth form a shunt between the two wires of very low resistance. Then a short circuit takes place on the whole of the plant, which even if it lasts only a short time, may damage the machinery very seriously. It is clear that a short-circuit to earth through the lightning arresters is produced much more easily the higher the working pressure and power of the plant.

Telegraphic and telephonic lines are sufficiently protected by simple comb arresters, because the 100 or 200 volts, to which the pressure may possibly rise, is incapable of producing an arc across an air-gap of a few millimetres. The protection of a high-pressure line is a very difficult matter, and that explains how certain safety devices have succeeded in some cases and have completely failed in others.

A complete system of protection should fulfil the following requirements:—(1) To protect the line from direct discharges; (2) to prevent oscillatory discharges from jumping directly from the wires to the poles or to earth; (3) to prevent the discharges from reaching the machines; (4) to prevent the lightning arresters from forming a short circuit on the installation.

The protection of the line from direct discharges can be done with pointed rods, or better, with a group of pointed rods fixed on the poles and well connected with earth. In many cases the method was carried out of placing above the conductors a barbed wire which runs the whole length of the line and is put to earth at different points. It appears to give a negative result, however, so that now it is no longer used, at least in Europe. It may be said that while it protects against direct discharges, it does not protect from secondary effects, and hence it was discarded.

Electrical oscillations, like the harmonic vibrations of a stretched string, assume the form of nodes and ventral segments, and in order that a lightning conductor may act, it must be fixed on the line near one of the nodes, but where these may occur from time to time is a question of the greatest uncertainty. A great number of lightning conductors must then be placed along the line, a number which experience alone can decide in special cases.

The third requisite does not present much difficulty in satisfying. It is only necessary to place a lightning arrester on the machine to be protected, and to have the two alternative paths as different as possible, making that to the dynamo or transformer of a very high inductance, and that to earth of the smallest possible inductance. The discharge will then choose the second, even if it has to jump over a considerable air space in order to do so.

The inductance of the line to the dynamo or transformer is augmented by inserting a coil composed of a dozen fairly large turns which do not contain oil. Such a coil presents a very high impedance to oscillatory discharges, and a very small impedance with the ordinary working frequency. Referring to the phenomenon of nodes and ventral segments, M. Wurtz is not content with a single coil, but inserts numerous lightning arresters in the hope that he may obtain a coincidence with one of these. How he determines the number of the apparatus is not quite clear, and he has not indicated his theory. The earth conductor ought to be as straight as possible in order to present a minimum impedance. Oscillatory discharges do not lend themselves readily to sudden change of direction, and a sharp bend offers a high impedance; hence the necessity for short and good earth connections. Moist earth is very good, but water by itself is bad. The surface of the earth plate should be as large as possible.

The last point, *i.e.*, to prevent the discharge forming a short circuit on the plant, brings us to the discussion of the lightning arrester itself. A very good thing, generally speaking, is to place in the lightning conductor a high ohmic resistance, whose co-efficient of self-induction is small—for example, a carbon rod. This limits the flow of current and reduces the damage arising from a short circuit. Another arrangement, absolutely necessary, is that of making each lightning arrester have a separate earth. To join all the earths into a single one is very dangerous, because it makes the ultimate resistance of the short circuit practically nil. Apparatus have been invented by the hundred. Those which have given the best results up till now are the Wurtz type and the Siemens type.

The Wurtz apparatus made by the Westinghouse Company is composed of a series of small cylinders of a special kind of

Digitized by Google

brass containing a large amount of zinc, arranged in line with an air space of about ½mm. between each. In consequence of a discharge an arc is not usually formed, and though this is a known fact, the reason is not very well established. In America, the General Electric Co. makes a lightning arrester called the Wirt, which does not differ from that of Wurtz, except in theory. Wurtz attributes the power of extinguishing the arc to the action of oxide of zinc, while Wirt says it is due to the cooling action of the metallic masses.

In the Siemens lightning arrester the arc formed is broken by electro-dynamical means. The apparatus is made of two pieces of copper wire brought close together at the base and separated above so that it has the appearance of two horns. The line is attached to one of the wires, the earth to the other. When a discharge jumps across the air space between the two wires, the arc which is formed is, by a well-known electro-dynamical effect, driven towards the ends, where it becomes elongated, and the action of the hot air makes it curve upwards until it is broken. All this lasts in general only a few seconds, and there are no dangerous results. Sometimes, however, the duration is greater, and then the short circuit which ensues may produce a considerable drop of pressure, but this is better than injury to the plant. In the present state of the question, we have thought it wise to test both of these systems on the line of Paderno, and experience will decide which is the better.

The line reaches Milan at the station of Porta Volta, where it is received on a suitable switchboard. From the switchboard the currents are conveyed to the transformer chamber. The transformers are supplied by the firm of Ganz and Co., are of the three-phase type and have a ratio of 12,000 to 3,600 volts. Their construction is quite simple. They consist of three columns of laminated iron disposed in one plane. On each column are wound a number of coils belonging alternately to the primary and the secondary circuit. This type is criticised by some from the point of view that not having the three magnetic circuits equally long it may give rise to a dissymmetry of the system. But the objection appears unfounded, and it is always possible in our case, where the transformers are numerous, to connect them in such a way as to compensate for the dissymmetry. The output of each transformer is 350 kilowatts, and its dimensions are:—height 6·9ft., length 6·56ft., width 3·28ft., and weight 7·75 tons. The secondaries of these transformers are carried to a switchboard which forms part of the general switchboard of the station at Porta Volta.

[*Note by the Translator.*—Since translating the above description of the central station of Paderno, I have received the following interesting information from Signor Semenza:—The works were commenced in February, 1896. Water was admitted into the canal in August, 1898, and the current was put on the line on September 28th. Public supply was given in Milan from Paderno on October 15th for the three-phase distribution and Edison network, and on October 29th for the traction service. The experience of a month or two is not enough to judge of the ultimate success of such a scheme, but it is highly satisfactory to know that the high-tension worked perfectly, the dynamos gave their guaranteed efficiency, and the line losses were exactly as calculated.—J. R. D.]

MODIFIED BRIDGE METHOD OF MEASURING RESISTANCES CONTAINING EARTH CURRENTS.

BY R. R. BLACK, ELECTRICIAN TO THE EASTERN EXTENSION TELEGRAPH COMPANY.

The following is a simple method of measuring the resistance of a cable by reversals when earth currents are strong and variable. It is a more sensitive method than the false zero unless the latter can be taken without a shunt on the galvanometer; it saves the lengthy calculation for correcting reversals taken by the ordinary Wheatstone bridge method, and the resistance of the battery is not required to be known. Three arms of the bridge a, b and d are fixed, and an adjustable resistance, R, is inserted between the bridge and cable R is then adjusted until balance is obtained to instrumental zero. The current to line is then reversed, and balance is obtained again to instrumental zero by altering R to R_1. Then

$$x = d\frac{a}{b} - \frac{R + R_1}{2}.$$

That is the fixed resistance d multiplied by the ratio $\frac{a}{b}$, minus the arithmetical mean of the two readings, R and R_1, give the true resistance of x. With even bridge

$$x = d - \frac{R + R_1}{2}.$$

The formula is found as follows:—

C and C_1 = currents flowing along d and x respectively.
e the E.M.F. of earth current in the line.
a and b = bridge ratios.
x = resistance of line.
d = the fixed resistance.
R = The variable resistance between bridge and line, with zinc current to line.
R_1 = The variable resistance between bridge and line with c to line.
E = E.M.F. of battery.

When balance is obtained to instrumental zero the potential at A is equal to the potential at B;

$$\therefore\ ac_1 = cb, \qquad \therefore\ c = c_1\frac{a}{b};$$

also $$Rc_1 + xc_1 \pm e = dc.$$

Substitute value of c we get

$$Rc_1 + xc_1 \pm e = d\frac{a}{b}c_1. \tag{1}$$

Reverse the testing battery and readjust R to R_1.

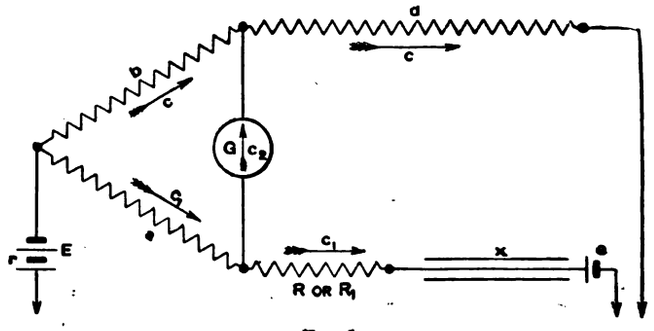


FIG. 1.

As the ratio arms and d are fixed, when balance is again obtained with E reversed, the values of the currents in the figure are the same as before, but in the opposite direction.

Therefore $$-R_1c_1 - xc_1 \pm e = -dc$$

substitute value of c

$$-R_1c_1 - xc_1 \pm e = -d\frac{a}{b}c_1. \tag{2}$$

Substract (1) and (2)

$$Rc_1 + xc_1 + e + R_1c_1 + xc_1 - e = 2d\frac{a}{b}c_1,$$

$$R + R_1 + 2x = 2d\frac{a}{b};$$

$$\therefore\ \frac{R + R_1}{2} + x = d\frac{a}{b},$$

$$\therefore\ x = d\frac{a}{b} - \frac{R + R_1}{2}. \tag{3}$$

If ratio equal $$x = d - \frac{R + R_1}{2}. \tag{4}$$

When the earth current opposes the line current it is equivalent to a resistance in effect (*see* "Student's Guide to Submarine Cable Testing," p. 40). Consequently d must allow for this. As a rule, if d is made about 25 per cent. higher than the estimated value of $x\frac{b}{a}$, before beginning the test, it will not be necessary to make any alteration in it.

Digitized by Google

For example :—

With this plan of connections the resistance usually employed for the ordinary test can be varied, and the extra resistance box d can be fixed.

a and b were 1,000 ohms each and the number of cells 10. The approximate resistance of x was 4,000 ohms. Adding 25 per cent. to $4{,}000\frac{1{,}000}{1{,}000}$, to allow for the resistance effect due to the EC, d was made 5,000 ohms.

Zinc was then put to line, and balance was obtained to instrumental zero, when 556 ohms were unplugged in R.

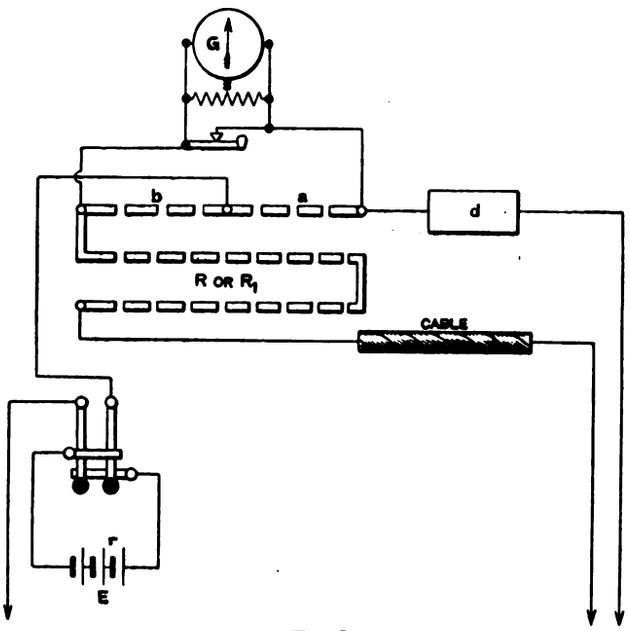

FIG. 2.

The line current was then reversed, and balance R_1 was obtained to instrumental zero with 1,676 ohms unplugged.

Therefore by formula

$$x = 5{,}000 \times \frac{1{,}000}{1{,}000} - \frac{556 + 1{,}676}{2} = 3{,}884 \text{ ohms.}$$

The following are actual examples :—

Example I.

Ratio 1,000/1,000 20 cells. Fixed resistance $d = 6{,}000$ ohms.

R 543	R_1 773	Mean 658 ohms.
548	774	,, 661 ,,
548	776	,, 662 ,,
548	775	,, 661 ,,
549	775	,, 662 ,,
		,, 661 ,,

6,000 - 661 = 5,339 ohms.

Example II.—*Reading by False Zero = 5,335 ohms.*

Ratio 1,000/1,000 20 cells. Fixed resistance = 8,000 ohms.

R 858	R_1 978	Mean 918 ohms.
858	971	,, 914 ,,
853	973	,, 913 ,,
853	974	,, 913 ,,
858	971	,, 914 ,,
		,, 914 ,,

8,000 - 914 = 7,086 ohms.

Example III.—*Reading by False Zero = 7,090 ohms.*

Ratio 10,000/10,000. Fixed resistance 17,040 ohms.

R 7,655	R_1 1,470	Mean 4,562 ohms.
7,660	1,495	,, 4,577 ,,
7,415	1,690	,, 4,552 ,,
		,, 4,563 ,,

17,040 - 4,563 = 12,477 ohms.
Reading by False Zero 12,500 ohms.

In the last case, the fixed resistance had to be 50 per cent. higher than the actual resistance of x owing to the strong earth currents.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *December 30, 1898.*

Obituary.—Mr. R. T. McDonald, president of the Fort Wayne Electric Corporation, Fort Wayne, Ind., one of the most widely known men in the electrical manufacturing business in this country, died suddenly of pneumonia in Dallas, Texas, on the morning of December 24. Mr. McDonald was 49 years of age. He was of Scotch descent but of American parentage. He was a man of marked ability and was connected in various business and financial enterprises in many places throughout the United States.

Dr. Welling Adams, of St. Louis, Mo., who was a prominent figure in the electrical world a few years ago mainly through his scheme about six years ago to build a high-speed electric railroad between St. Louis and Chicago, died at his home in St. Louis on December 19 of pneumonia, at the age of 42 years. Of late years, Dr. Adams's personality has almost been forgotten in the electrical field. He, within a year or so, made the claim that he was the original inventor of the method of applying electric power directly to the axles of cars, but he received no support whatever in the courts.

Automobile Stages on Fifth Avenue.—For many years a line of horse omnibuses has been running along Fifth Avenue in this city and the antiquated system of travel has been the subject of a great deal of comment in the public Press at different times. Several officers of the Third Avenue Railroad Co., which is now equipping its lines with electric power, have purchased the old omnibus line for the purpose of introducing motor 'buses and retiring the horses. It has not yet been decided what method of propulsion will be adopted on the new vehicles, but there is a strong likelihood that it will be electricity. The fact that Dr. Louis Duncan, a well known electrical authority, is consulting engineer of this enterprise, would seem to indicate that he would naturally favour electricity, if in his judgment it will meet all the requirements of the service. Fifth Avenue is the fashionable residence street of the city, and the possibility of ever getting car tracks down on the thoroughfare is so remote that no one has ever attempted to secure a franchise.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

NEW BOOKS AND EDITIONS.

The following New Books and Editions can be obtained of the Booksellers or direct from the Publishing Offices, 1, 2 and 3, Salisbury-court, Fleet-street, London :—

NOW READY.

"ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS."—By J. Elton Young, M.I.E.E. The scope of the book aims at furnishing a fuller treatment of the subject, from the standpoint of the Telegraph Engineer, than it has hitherto received, whilst it endeavours to facilitate a thorough comprehension of the theory of testing as applied to electrical lines in general. The Author hopes that, besides Telegraph and Telephone Engineers, it may, perhaps, also prove of service to those in charge of cables for the transmission of light and power. The localisation of faults has been very fully investigated, including the different degrees in which the various methods are affected by the presence of a second fault or of general leakage.—*Extract from Preface.* Demy 8vo, fully illustrated. 10s. 6d., post free; abroad 11s.

"SUBMARINE CABLE-LAYING AND REPAIRING."—By H. D. Wilkinson, M.I.E.E., &c., fully illustrated; price 12s. 6d.

"THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING."—A new work by Messrs. H. K. C. Fisher and J. C. H. Darby, with the above title, is now ready, price 6s. net; abroad, 6s. 3d. This work is intended to serve as a guide to operators already in the telegraph service, and to those who desire to enter that service. The great cable companies now insist that their operators and probationers shall pass certain examinations in electrical subjects. The book is very fully illustrated. *Second Edition now ready.*

"PRACTICAL NOTES FOR ELECTRICAL STUDENTS."—By Messrs. A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free.

"ELECTRO-CHEMISTRY."—By Dr. G. Gore. Third Edition. Price 2s., post free.

"WIRELESS TELEGRAPHY: SIGNALLING ACROSS SPACE WITHOUT WIRES BY ELECTRIC WAVES."—By Dr. O. J. Lodge, with many original illustrations. *Enlarged Edition*, 2s. 6d. net, 2s. 9d. post free.

Digitized by Google

"ELECTRIC MOTIVE POWER," by Albion T. Snell, contains the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d., post free; abroad, 11s.

"LABORATORY NOTES AND FORMS."—With the above title we have ready the New Edition of a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators and Students. The object of this series is the saving of the time of the Teacher and his Assistants, and to serve as a record of the work done by the Student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen net; in sets of any three, 1s. net; or the set of Twenty (Elementary or Advanced) Exercises can be obtained, price 5s. 6d. net. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. net; or in handy portfolio, price 12s. net; or bound in strong cloth case, price 12s. 6d. net. Strong portfolios can be had, price 1s. each.

NOW READY.—The cheaper edition of Dr. J. A. Fleming's "Electrical Laboratory Notes and Forms." These cheaper Forms have been prepared for the use of students and teachers at the Polytechnic and other science classes throughout the country. The demand for the original set of these Notes and Forms has led to a request for a cheaper set for use at the day and evening classes at many of the technical institutes. These new Forms, which differ only from the higher-priced set in being printed on smaller and cheaper paper and with less space for tabulated records, are issued at half the price of the original set.

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready. Price 7s. 6d.; abroad, 8s.

"THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS."—Edited and enlarged by W. Worby Beaumont. Price 3s. 6d., post free.

"THE ART OF ELECTROLYTIC SEPARATION OF METALS."—A second issue of Dr. Gore's book is now ready, price 10s. 6d., post free.

"THE MANUFACTURE OF ELECTRIC LIGHT CARBONS."—A Practical Guide to the establishment of a Carbon Manufactory. Fully illustrated. price 1s. 6d.; post free, 1s. 9d.

"THE BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH, 1896-97." A valuable, up-to-date compilation. Being an attempt to classify the data relating to X-Ray work. This work contains a quantity of general as well as special information bearing upon the whole subject of electrical discharge research. Price 5s., post free; abroad, 5s. 3d.

"LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS."—By F. C. Raphael. Price 5s., post free; abroad, 5s. 6d. Prospectus on application.

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book, by Messrs. W. Geipel and H. M. Kilgour; price 7s. 6d.; by post, 7s. 9d.; abroad, 8s. A fine large paper edition with wide margins for notes can also be supplied. Price 12s. 6d.; post free, 13s.; abroad, 13s. 6d. *New Edition in the press.*

"THE ALTERNATE CURRENT TRANSFORMER," Vol. I.—By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. *New Edition.* Price 12s. 6d., post free. Vol. II., price 12s. 6d. post free, is also ready.

"ELECTROMAGNETIC THEORY."—By Oliver Heaviside. Vol. I., price 12s. 6d.; post free, 13s.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free.

"THE ELECTRICIAN" PRIMERS.—In Two Volumes. Vol. I., Theory. Vol. II., Practice. Price, stout paper cover, 2s. 2d. each, post free; cloth, 2s. 9d. Single Primers, 3d. each, post free.

"ARMATURE WINDINGS OF ELECTRIC MACHINES."—By H. F. Parshall and H. M. Hobart. This work has been compiled from notes made by Mr. Parshall in his capacity as Chief Designing Engineer of the Edison and General Electric Companies of America, and is intended to serve as a working treatise on dynamo design. Large 4to, 370 pages, 140 full-page illustrations and 65 full-page tables, 30s., post free.

"DRUM ARMATURES AND COMMUTATORS," by Mr. F. Marten Weymouth, also ready. Price 7s. 6d.; abroad, 8s. Prospectus on application.

"THE POTENTIOMETER AND ITS ADJUNCTS": A Universal System of Electrical Measurement.—By W. C. Fisher. Fully illustrated. Price 6s., post free; abroad, 6s. 6d. Digest post free.

"MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY."—By E. Tremlett Carter, C.E., M.I.E.E. Price 12s. 6d., post free; abroad 13s. 6d. Prospectus post free.

IN THE PRESS.

"THE ELECTRIC ARC."—By Mrs. Ayrton.

"THE MANUFACTURE OF CARBONS FOR ALL ELECTRICAL PURPOSES."—By Francis Jehl.

"ELECTROMAGNETIC THEORY."—By Oliver Heaviside. Vol. II.

"SECONDARY BATTERIES, THEIR DESIGN AND MANUFACTURE."—By E. J. Wade.

"PRIMARY BATTERIES: THEIR CONSTRUCTION AND USE."—By W. R Cooper.

"PRACTICAL TELEPHONY."—By Dane Sinclair and F. C. Raphael.

"'THE ELECTRICIAN' WIREMAN'S POCKET-BOOK."

"The Electrician" Electrical Trades' Directory and Handbook.—An important announcement in connection with the 1899 issue of the "Big Blue Book" will be found in an advertisement on another page of the present issue, to which our readers will please refer.

Electricity Supply Data and Statistics.—In the large sheet tables of electricity supply statistics issued with *The Electrician* for Jan. 6 there were some omissions which we hope to remedy in the final issue of the tables the first week in February, when the tables will form part of "The Electrician" Electrical Trades' Directory and Handbook for 1899. and will also be obtainable on rollers and in cloth cases. The Editor will be obliged if station engineers and others who can assist in completing the table will send in particulars as to: (1) The total capital expenditure to Dec. 31, 1898 (actual or approximate); (2) The total units generated for year to Dec. 31, 1897 (actual); (3) Units generated for year to Dec. 31, 1898 (actual or approximate); (4) Any other particulars which will help to make the table fully complete to Dec. 31, 1898. It is hoped that the information sought will reach *The Electrician* office by Jan. 23.

TENDERS INVITED.

The *Metropolitan Asylums Board* invite tenders for the supply and erection of the following electric lighting plant at the Northern Hospital, Winchmore Hill, N. :—(1) Switchboards, booster and connections; (2) battery; (3) electric mains; (4) steam exhaust, feed and drain pipes; and (5) wiring and fittings. Further particulars are given in an advertisement, and copies of specifications and drawings (by Messrs. Burstall and Monkhouse) may be obtained at the office of the Board, Norfolk House, Norfolk-street, Strand, London, W.C. Tenders must be lodged by 10 a.m. of 25th inst.

The Commissioners of *Govan* invite tenders for the supply and erection of (1) water tube boilers and feed heater; (2) engines and dynamos, equalising transformer, boosters, &c.; (3) lead-covered armoured cables; (4) storage batteries; (5) arc lamps; and (6) arc lamp pillars. Specifications may be obtained from Mr. Arnot, C.E., 79, West Regent-street, Glasgow, and tenders must be delivered to the town clerk (Mr. A. Macdonald), Hillock House, 752, Govan-road, Govan, by 23rd inst. Further particulars are given in an advertisement on another page.

The Corporation of *Lowestoft* invite tenders for the supply and erection of the following plant:—(*a*) boilers and fittings, economisers, feed pumps, &c.; (*b*) pipe work, &c., for engine and boiler house; (*c*) steam dynamos and motor boosters; (*d*) storage batteries; (*e*) main switchboard and connections; (*f*) overhead travelling crane; (*g*) underground mains and conduits, road work, &c.; (*h*) arc lamps and posts; (*i*) station lighting. Plan, &c., may be obtained at the offices of Mr. W. C. C. Hawtayne, consulting engineer, 9, Queen-street-place, London, E.C., after 16th inst. Further particulars are set out in an advertisement elsewhere, and tenders must be addressed to the Town Clerk, at the offices, 115, High-street, Lowestoft, by noon of Feb. 6.

As announced in an advertisement, the Electricity committee of the *Belfast* Corporation invite tenders for the supply of the following:—Cast iron pipes, cast iron frames and covers, earthenware conduits, insulated cable, and Lancashire boilers. Specifications and conditions of contract may be obtained from Mr. Victor A. H. M'Cowen, city electrical engineer. Tenders must be lodged with the town clerk (Sir Samuel Black), City Hall, Belfast, by Thursday, Feb. 2.

The Commissioners of the Burgh of *Stirling* invite tenders for the supply of mains. Specifications can be obtained from the clerk to the commissioners (Mr. Thomas L. Galbraith), and specifications and drawings may be seen at, but not obtained from, the office of Prof. Alex. B. W. Kennedy, 17, Victoria-street, London, S.W. An advertisement contains further particulars, and tenders must be delivered at the Town Clerk's Office, Stirling, not later than 30th inst.

The *Sunderland* Corporation require tenders for road work with stoneware casings, and supplying and laying cables. Specifications, &c., can be obtained from the borough electrical engineer (Mr. J. F. C. Snell), and tenders, addressed to the chairman of the Lighting committee, Town Hall, Sunderland, must be delivered at the office of the town clerk (Mr. Fras. M. Bowey), by Friday, 27th inst. Further particulars are given in an advertisement on another page.

The *Ealing* (London) Council require tenders for two 500 H.P. steam alternators, and one 150 H P. steam dynamo alternator. Tenders to the clerk, Public Buildings, Ealing, W., by 30th inst.

The *Southampton* Corporation invite tenders for the supply of transformers and fittings. Tenders to the town clerk (Mr. George B. Nalder), Municipal Offices, Southampton, by 2 p.m., 16th inst.

The *Glasgow* Corporation invite tenders for providing and erecting generating plant at one or other of their new electricity works. Tenders to Sir J. D. Marwick, City Chambers, Glasgow, by *Saturday, Jan. 21.*

The *London* County Council invite tenders for four continuous-current dynamos, one motor generator, two switch-boards with switches, measuring instruments and other work required for the proposed Victoria Embankment electric generating station. Tenders to Mr. C. J. Stewart, County Hall, Spring-gardens, S.W., by 10 a.m., Jan. 31.

The *London* County Council also require tenders for the erection of four gas engines at the proposed Victoria Embankment electric generating station. Tenders to the clerk by 10 a.m., Jan. 31.

Digitized by Google

The *Shanghai* Council invite tenders for a concession, for a period of thirty years, for the exclusive right of establishing and working a telephone system in Shanghai.

The *Shanghai* Council also invite tenders for a concession for constructing and working about 23 miles of electric tramways on the trolley system. Particulars of both contracts from Messrs. John Pook and Co., 8, Jeffrey's-square, London, E.C. Tenders to Mr. J. O. P. Bland by noon of March 31 and 15, 1899, respectively.

The Compagnie Generale de Traction, of *Brussels*, invite tenders until the 25th inst., for the supply of 9,000 porcelain insulators and 10 tons of galvanised iron wire, &c.

TENDERS RECEIVED AND ACCEPTED.

The Accrington Town Council have let tenders for the supply of electric lighting plant as follows :—

Steam dynamos, Johnson and Phillips	£2,991	10
Storage battery, Chloride Electrical Storage Syndicate	910	0
Instruments, Crompton and Co.	641	0
Cables and street boxes, W. T. Glover and Co.	4,550	0

APPOINTMENTS VACANT AND FILLED.

The Wigan Corporation require an electrical engineer competent to draw up and carry out an electric lighting scheme (with or without tramways). An advertisement elsewhere gives further particulars, and applications must be sent to the town clerk (Mr. J. J. Charnock), Wigan, by 16th inst.

The Lighting committee of the Canterbury Town Council require an assistant electrical engineer (salary £104 per annum), two junior electricians (£52 per annum each), one stoker, one lamp trimmer and cleaner, a jointer and an assistant jointer. Additional particulars are given in an advertisement, and applications must be sent to the town clerk (Mr. Henry Fielding), 15, Burgate-street, Canterbury, by 10 a.m., 17th inst.

The Oldham Corporation require an assistant engineer for their electricity works. Further particulars are given in an advertisement. Applications to the chief electrical engineer, Electric Supply Station, Oldham, by the 16th inst.

As will be seen from an advertisement elsewhere applications are invited for two shift engineers for the Cropper's Hill power station of the St. Helens Corporation. Applications on or before Monday, 23rd inst.

The Worcester Corporation require two improvers as switchboard attendants. There are also vacancies for two pupils at the electricity works. Applications to city electrical engineer (Mr. C. J. Sutherland). See advertisement.

The Electric Lighting Committee of the Portsmouth Corporation are prepared to take pupils with a mechanical training. Particulars from the superintendent (Mr. E. Price), Corporation electricity works, Portsmouth. See advertisement.

The Professorship of Physics at the University of Sydney is vacant. Salary £900 per annum. Particulars from the acting Agent-General for New South Wales, 9, Victoria-street, London, S.W.

The Metropolitan Asylums Board require an assistant engineer with experience in electric lighting. Salary £300 per annum. Applications to Norfolk House, Norfolk-street, W.C., by 23rd inst.

Mr. N. Staniland has been appointed electrical engineer by the Canterbury Town Council at a commencing salary of £200 per annum.

BUSINESS NOTICE.

Owing to the increasing trade in the Midlands, the Birmingham offices of the Edison and Swan Company have been removed to larger and more convenient premises, International Exchange Buildings, Edmund-street, where an extensive show-room is being fitted up for the display of electroliers and brass fittings generally.

The British Thomson-Houston Co. (Limited) announce that they have opened branch offices at 21, Lincoln-place, Dublin. Telegraphic address, "Asteroidal Dublin," telephone 320. Mr. Arthur Jacob is resident engineer.

Messrs. W. J. Crampton and Co. have removed their offices and showroms from 3, Theatre-buildings, Regent-road, to 25, Regent-street, Great Yarmouth.

Messrs. E. J. Mather and A. A. Mather, trading as Mather Bros., electrical engineers, 278, Caledonian-road, N., and 73, Farringdon-street, E.C., London, have dissolved partnership. Debts by Mr. A. A. Mather.

Messrs. C. C. Wardrop and C. A. V. Whitaker, electrical and civil engineers, 1, Army and Navy Mansions, Victoria-street, London, S.W., have dissolved partnership. Debts by Mr. Wardrop. Mr. C. F. Monckton, late engineer and manager of Messrs. Bousted Bros.' electrical department, Ceylon, has joined Mr. Wardrop, and the new firm will practice as civil and electrical consulting engineers under the style of Wardrop and Monckton, at the above address.

Mr. H. T. Boothroyd (late of Messrs. Laird Bros., Birkenhead) is commencing business under the title of H. T. Boothroyd and Co., mechanical and electrical engineers, Miller's Bridge, Bootle. He has acquired the business of Messrs. W. and J. Robinson (Limited), and the new firm make a speciality of dynamos, motors, ship lighting and general electrical work. Mr. W. Robinson acts as manager.

BANKRUPTCIES, LIQUIDATIONS, &c.

Official notice is given that Mr. G. Franklin, Broomfield, and Mr. J. Gamble, Southborne, Sheffield, have been appointed liquidators in the voluntary liquidation of the Sheffield Electric Light and Power Co. (Limited), whose undertaking has been acquired by the Corporation.

It has been resolved to wind up voluntarily the Improved Incandescent Electric Lamp (Foreign Patents) Syndicate (Limited), and Mr. R. Ballard, 20, Jewry-street, E.C., has been appointed liquidator.

At a meeting of the London and Hampstead Battery Co. (Limited) it was resolved to wind up the company voluntarily, and to appoint Mr. R. J. S. Beeton, 23, West-hill, Sydenham, S.E., and Mr. S. T. Turtle, 141, St. John's-hill, Wandsworth, S.W., liquidators.

At a recent meeting of the Northern Counties Electric and Motor Co. (Limited) it was resolved to wind up the company voluntarily, and to appoint Mr. J. Robinson, Lightcliffe, Yorks., liquidator.

A first meeting of the creditors of John Evelyn Lairdet, inventor and patentee, was held in London last week. Debtor failed in 1888, but has received his discharge. Proofs of debts to the amount of £8,458 were lodged. The assets include debtor's interest in electric accumulators, electric motor cars, water motors, &c., and he claims that if these are properly worked and perfected they will will realise more than 20s. in the £. He attributes his failure to expenditure in completing his inventions. It was pointed out on debtor's behalf that the receiving order had been obtained by accident, and that steps were being taken to set it aside, debtor being desirous of submitting a proposal to his creditors. The meeting was adjourned to Feb. 3.

Last week at the London Bankruptcy Court the adjourned meeting of creditors of E. B. Pym, electrical engineer, late of Scarborough, was held. No statement of affairs has been filed. Debtor will undergo preliminary examination at Taunton. It was stated that debtor is entitled to an income which is alienable upon bankruptcy. The meeting was further adjourned to 30th inst.

Claims against John Dewhurst, electrician, &c., 52, North End-road, West Kensington, London, W., must be sent to the trustee, Mr. Hough, Bankruptcy-buildings, London, W.C., by 21st inst.

In the Chancery Division, Mr. Justice Wright made an order continuing the voluntary winding-up of the Mannesman Tube Co., under the supervision of the Court.

Mr. Thomas King, electrical engineer, recently carrying on business at Invicta Works, St. Peter-street, Maidstone, and at Brighton, was publicly examined at Maidstone last week. Debtor stated that he commenced business on his own account in Brighton in 1891 with a capital of nearly £600. He had managed Mr. Robert Dann's business at Maidstone for several years. Examination adjourned for explanations from the debtor.

Prism Globes.—The Prism Globe Syndicate (Limited) have now ready a new price list of prism globes, including "oval," "spherical," "acorn" and "pine" shapes. The prices of these globes, for which great economy is claimed, have been recently considerably reduced.

Crossley Gas Engines.—Messrs. Crossley Brothers have secured an order from the London County Council for what is claimed to be the largest installation of gas engines ever put down in any part of the world. Eight double cylinder horizontal engines, four of a maximum I.H.P. of 260 each, and four of 210 I.H.P. each, are to be supplied, as well as four of 5 I.H.P., combined with air compressors and hydraulic pumps. The large engines are to be built on the "tandem" principle and all are to work with coal gas. The engines will be used for driving centrifugal pumps at the Lots'-road pumping station. This is the second order Messrs. Crossley have received from the Council for pumping engines.

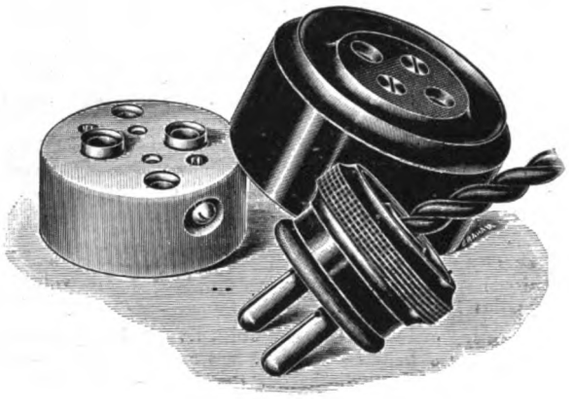
E.P.S. Cells.—There has recently been an alteration in the price of the Electrical Power Storage Co.'s K.W.S. type of cell, and new lists showing the alterations can now be obtained of the company.

"Neptune" Copper Rail Bonds.—Messrs. W. F. Dennis and Co., of 23, Billiter-street, London, E.C., forward a new list of "Neptune" copper rail bonds, manufactured by Messrs. Felten and Guilleaume, for whom Messrs. Dennis and Co. are the sole agents for the United Kingdom. The list is illustrated, and shows on page 2 a multiple bond for heavy rails carrying large currents.

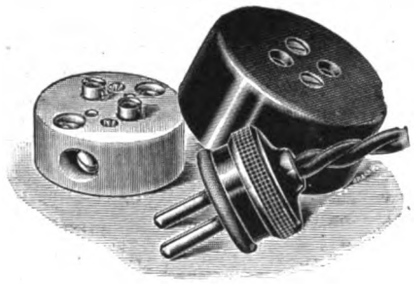
Digitized by Google

A large number of these bonds have been supplied for use on the Glasgow tramways to the corporation officials' own designs. It is claimed for these bonds that they possess the advantage that the steel pins are driven from the same side that the bonds are put through the web of the rails, an important point where conversion from existing horse or steam tramways is to be adopted, as by the use of this method the road need only be opened on one side. The list also illustrates patent screw bonds, &c.

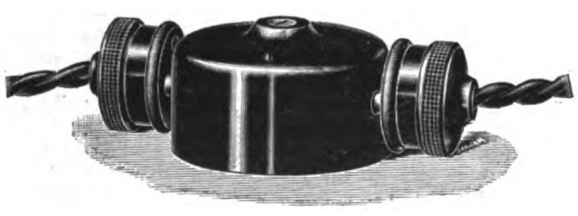
"Lundberg" Accessories.—The mention of Mr. Lundberg's name seems naturally to suggest improvements in switches, plugs, &c., for with clockwork regularity we seem to receive samples of



Mr. Lundberg's excellent work in this department. We are not surprised to learn that the demand for the various types of these accessories, manufactured at the Bradbury-street works, is an increasing one, for the work in the specimens we have received from time to time has been excellent. A sample of a new "Universal" high voltage wall connection without fuse terminals and fitted with the "Ridge" type of cover is here illustrated, the principle of construction being, Mr. Lundberg claims, quite novel. All the metal parts are thoroughly protected against possible leakage of current



To provide a proper insulating bridge between the ends of the contact tubes when the circuit is broken by withdrawal of the plug, holes are countersunk in the roof of the cover to admit the ends of the contact tubes. Long experience convinces Mr. Lundberg that this is the simplest and most satisfactory method, as the length of contact pins is kept down to reasonable limits. The plugs and sockets are of similar gauge, and consequently interchangeable with those supplied by the firm since 1884, and with each other.



The contact tubes are of extra stout metal and are pierced at their base by horizontal holes; through these pass studs screwing into the pillar terminals and clamping them solidly into contact with the tubes. We also illustrate the "Dot" wall connection similarly arranged for high insulation, and in which the diameter has been somewhat reduced owing to improved construction and absence of fuse terminals. The third figure shows the "Dot" twin wall connection. Mr. Lundberg was the original introducer of twin socket plugs. In the present case he has adopted side-entering plugs, so that the fitting stands only a minimum distance from the wall when fixed. At present this article is only made to suit the "Dot" gauge.

Catalogue.—The British Thomson-Houston Co. send us a copy of their recently-issued catalogue, No. 1,005, which consists practically of a well-gotten-up album of illustrations of motor work of every description undertaken by these contractors. The execution of this publication is artistic, and the range of subjects in the 25 illustrations shows to what a great variety of purposes electric motors are now put. Unlike most books printed in English, this one commences (with page 825) on what is usually the last page, and ends on page 854, where a Western naturally looks for the beginning of the story. However, as an album can generally be glanced through with equal pleasure in any order, Oriental or Western, users of this catalogue will suffer no inconvenience from the adoption of the Japanese plan. Perhaps this elasticity of arrangement is intended to indicate the fact that the electric motor is as triumphant in the East as in the West.

Calendars.—We have to acknowledge the receipt of a useful hanging pad calendar from the Commercial Cable Co.

———From the Cape Asbestos Co. (Limited) we have received a handy desk blotting pad and calendar, which is built to last the year through.

"Automotor" Pocket Book.—We have received the 1899 issue of the "Automotor and Horseless Vehicle Pocket Book," published by Messrs. F. King and Co. The book contains a large amount of useful information regarding horseless vehicles, and, in addition to much matter usually to be found in annual publications of this character, gives tables and technical data which will be of service to the automotor engineer and constructor. The book is price 1s.

Exports of Electrical Apparatus and Material.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from Jan. 4 to Jan. 10, with the ports of destination:—

Argentina—Buenos Ayres £825 (including £750 telegraph material). *Australasia*—Adelaide, £1,440 (including £907 telegraph material); Brisbane, £371; Fremantle, £2,575; Melbourne, £270 (telegraph material); Perth, £36; Sydney, £414; Wellington, £295. *Belgium*—Ostend, £51. *Denmark*—Copenhagen, £50. *Egypt*—Alexandria, £20,000 (telegraph cable). *Germany*—Cologne, £20; Hamburg, £63. *Gibraltar*—£780. *Holland*—Amsterdam, £30. *India*—Madras, £300. *Japan*—Yokohama, £1,317. *North Atlantic*—26 knots telegraph cable. *Norway*—Christiania, £112. *South Africa*—Cape Town, £680; Chinde, £75; Durban, £2,334 (including £2,314 telegraph material); Port Elizabeth, £58. *Spain*—Barcelona, £75 (telegraph cable). *Sweden*—Gothenberg, £22; Stockholm, £915 (including £885 telegraph material). *United States*—New York, £8. *West Indies*—Trinidad, £55. Total £293,171, against £18,683 in the corresponding week last year (Jan. 5to Jan. 11).

MUNICIPAL, FOREIGN AND GENERAL NOTES.

Adelaide (S. Australia).—We recently referred to the acceptance by the Town Council of Adelaide of a tender of the South Australian Electric Light Co. "for the electric lighting of the town." We are informed by Messrs. J. C. Lanyon and Sons, of Gresham House, Old Broad-street, London, E.C., that this statement is "incorrect and misleading." The following particulars, in support of this contention, are supplied by Messrs. Lanyon:—

"The gas company's contract for lighting the whole of the city of Adelaide (about 900 lamps) does not expire till September, 1902.

"The Adelaide Corporation have power under an Act of Parliament to supply electricity.

"The South Australian Electric Company's Act of 1897, clause 39, is as follows:—

'Except as to the Municipality of Port Adelaide, this Act shall only 'apply within the limits of such municipalities and districts, the Councils 'of which shall by public notice notify that, as the result of a poll, the rate-'payers have affirmed a resolution that it is desirable that this Act shall 'so apply.'

"The Adelaide Corporation wish to erect electric works and supply electricity, but a poll of the citizens in 1894 decided against the scheme.

"In August, 1898, the Corporation called for offers from persons willing to do *private electric* lighting in the city, such persons to state what they were willing to give for the privilege.

"The South Australian Electric Company agreed with the Corporation that a poll of the ratepayers should be taken, the Corporation to support the Electric Company in its endeavour to get ratepayers to affirm a resolution that it was desirable that the Electric Company's Act shall apply within the limits of the municipality; that the Corporation should not for ten years exercise its power of supplying electricity, nor transfer its powers to any other person or company; that the Electric Company would provide, erect, light and maintain 30 arc lamps (2,000 c.p.) for five years for one shilling per lamp per annum; that the Electric Company would deposit with the Corporation £2,000 and with the treasurer of the province £5,000; that a fine of 10s. per lamp per night for each lamp not lit and kept alight should be paid by the company; and that the contract did not in any way interfere with the existing contract with the gas company, which contract does not expire till September, 1902,

Digitized by Google

"On Sept. 17, 1898, a poll of the citizens of Adelaide was taken, when 2,761 (about one-fourth) of the ratepayers voted—1,775 for and 959 against."

Therefore (Messrs. Lanyon continue), for the privilege of doing private electric lighting in Adelaide for ten years, the Electric Company have agreed to provide, erect, light and maintain for the Corporation 30 arc lamps of 2,000 nominal c.p. each at 1s. per lamp per annum, which will mean a loss of £4,000 to the Electric Company.

The following particulars relating to the South Australian Electric Company were (we are informed) filed in the Supreme Court, Adelaide, in April, 1898:—Capital, £20,000 in 1,000 shares of £20 each; capital paid up, £13,655; number of shareholders, 16; number resident in Adelaide, 12. It will be interesting to have the views of the Electric Company. Meanwhile, as Messrs. Lanyon and Sons, presumably for the Gas Company, feel aggrieved at the statement in *The Electrician* of Oct. 21 last, we give the above statement on their authority.

Bradford.—The revenue account of the electricity department shows a total income of £20,059, and an expenditure of £8,736, leaving a trading profit of £11,323. After deducting interest and sinking fund (£7,060) the net profit is £4,263. The total profits made since the works were opened have been £19,045, and from this there has been written off for depreciation of plant £7,308, leaving unappropriated £11,737.

Brighton.—The Local Government Board having only allowed a period of 12 years for repayment of the loan of £56,300, recently sanctioned, the Corporation are asking to have this period extended to 25 years, as previously.

Burton-on-Trent.—After allowing for interest and sinking fund there was a deficiency of £992 in the accounts of the electric lighting department for the past year.

Chesterfield.—A special committee has been appointed to consider and report upon the advisability of establishing electricity supply works.

Dover.—The subject of acquiring the undertaking of the Dover Electricity Supply Co. was discussed at Tuesday's meeting of the Town Council, and was adjourned.

Edmonton.—The Local Government Board have sanctioned the Guardian's scheme for the electric lighting of the workhouse.

Electric Traction in Spain.—A company, entitled the Compagnie Generale des Tramways Electriques, has been formed at Brussels, with a capital of 10,000,000fr. (about £400,000), and is being financed by the Banque de Paris et des Pays Bas and the Banque de Bruxelles, to acquire the Madrid Eastern Tramways and the lines at Barcelona and Soria.

Garston.—At a special meeting of the District Council on Monday it was decided to transfer the provisional order to the British Insulated Wire Co.

Glasgow.—At a meeting of the Corporation, on Thursday last, it was decided to adopt the recommendation of the Tramways committee to equip the whole of the tramways on the overhead trolley system.

The city engineer (Mr. A. B. M'Donald) has been authorised to obtain estimates for carrying out the electric ventilating arrangements at the City Chambers set out in our last issue.

Great Yarmouth.—The report of the electricity department for the past quarter states that there are at present 314 customers, representing an equivalent of 14,839 8 c.p. lamps connected. The total income was £1,697. 15s. 2d., and the generation, &c., expenses, £758. 0s. 5d. Of the balance (£939. 14s. 9d.), repayments of capital, interest, &c., absorb £570, leaving a profit on the quarter's working of £369. 14s. 9d.

Hammersmith (London).—The Vestry are applying to the London County Council for a further loan of £56,000 for extensions of the electric light, plant and mains.

Hampton Wick.—Although some of the ratepayers in this district are anxious to obtain a supply of electric current the District Council has done, and apparently proposes to do, nothing to meet the demand. A ratepayer recently applied to the neighbouring (Kingston) Town Council for a supply of current, but the application was refused as the permission of the Hampton District Council could not be obtained. The matter was discussed at the last meeting of the Hampton Council, when one of the members said that the subject had been considered by them before, and the cost of a provisional order prevented them from moving in the matter.

Hartford (Cheshire).—The Parish Council have decided to adopt electric lighting, and an agreement has been entered into with the Northwich Electric Supply Co. for supply of current.

Hospital Lighting.—The Queen's Hospital, Birmingham, has been provided with an electric light installation of 350 16 c-p. incandescents.

Leamington.—The Corporation have decided not to sanction an application of the Midland Electric Light and Power Co. for a provisional order, as the Council is itself applying for an order.

Marylebone (London).—Last week the Vestry further considered the question of applying to Parliament for a special act to erect electricity works and to engage in the generation and sale of electric current for all purposes. After discussion it was decided to request the Electric Lighting committee to report to the Vestry as to the probable cost of the proposed scheme, and authorising the committee to engage the services of an expert adviser.

Merthyr.—The District Council have considered a report from Messrs. Handcock and Dykes on the application of the British Electric Traction Co. for a provisional order for the district, and will support the application.

Middleton.—The Town Council have decided to petition Parliament against the decision of the Board of Trade to confirm the order of the Light Railway Commissioners, empowering the British Electric Traction Co. to construct an electric railway through the town, and thus join up Oldham, Castleton and Manchester. They assert that powers have been exercised which Parliament never anticipated when it passed the Light Railways Act.

Municipalization Extraordinary.—On Tuesday a conference of the municipal authorities of Lancashire and Cheshire was held at Manchester to consider the advisability of organising concerted opposition to the Lancashire Electric Power Company's Bill and the South Lancashire and Cheshire Electric Power Bill next session. Councillor Vaudrey, Lord Mayor of Manchester, presided, and said the promoters of these Bills proposed to obtain power to go through towns in Lancashire and Cheshire, and to supply electric current for motive power and lighting purposes. These bills, therefore, trespassed upon the rights of the various towns, and he thought it was their duty to do their best, in the interests of the ratepayers, to secure the rejection of the bills on the second reading. The following resolution was then submitted to the meeting:—

"That this conference of municipal corporations of Lancashire and Cheshire, within the area comprised in these bills, protest against the same as violating the principle for which municipal corporations have in past years successfully contended, and which have been established by the Tramways Act of 1870, and the Electric Lighting Acts of 1882 and 1888, and determines to take united action in opposition to the bills."

Alderman Higginbottom, of Manchester, said the bills were really an attempt to deprive ratepayers of large towns like Manchester of the money which they had expended on their electricity undertakings, and if the bills were passed the recognised control of their streets would be done away with. It had already been claimed on behalf of the promoters that, for electric lighting purposes, the control was not in the hands of the municipal authority, and if they laid down electric mains and plant the Board of Trade could grant powers to a company for the same purpose. On the other hand, it was contended that competing powers were never given against a municipal authority, but the recent report of the Select Committee was to the effect that Parliament could sanction such bills which entered into competition with the schemes of municipal authorities, and that the Board of Trade should judge whether the bills should pass on their own merits. In Manchester they had arranged to supply electric current to a large number of towns. It was a mutual agreement, and no element of compulsion had entered into these arrangements, and he protested against such an extraneous body coming and opening out their streets and mains and putting down plant, whether they wanted it or not. If the companies had set out to do the work under an agreement with the corporations, many of them would perhaps not have objected, unless they had already spent large sums of money in putting down plant; but it was altogether against the principles of municipal government that such outside bodies should be allowed to interfere with their streets and thoroughfares. Mr. Charles Petrie, of Liverpool, said he could not agree with Ald. Higginbottom that companies might, perhaps, have been allowed to do the work under an agreement, as this was contrary to the best interests of the ratepayers, and ought not to be tolerated. He looked with very great dislike upon any interference by the Board of Trade with the rights of a municipality. Mr. Harcourt Clare, Town Clerk of Liverpool, said the main principle involved was that corporations which had undertaken to supply electric current should be subjected to competition by outside bodies. They had been induced and even encouraged by Parliament to borrow money in order to give an electrical supply, but at the present moment it was practically enjoyed by a very small percentage of the inhabitants in any borough. In Liverpool, out of a population of 700,000, only some 3,000 had the supply, and he would ask whether it was reasonable and right that any corporation should be allowed to pledge the credit of the whole body of ratepayers for the benefit of a small section, and that then outside companies should be permitted to compete with them. The municipalities ought to join and fight the matter out—not as a question of detail, but of principle—and get it settled once for all that, when a corporation had been authorised to spend money in any public undertaking, it should be freed from all outside competition. The resolution was carried unanimously, and an executive committee

Digitized by Google

was appointed to apportion the expense of opposing the bills among the different corporations comprised in the conference.

Nottingham.—A Local Government Board inquiry was held here on Wednesday into the application of the City Council to borrow £150,000 for electric light extension purposes. The town clerk (Sir S. G. Johnson) said the money was required to extend the plant and mains. As the present station was quite inadequate to meet the demands for electric current, the Corporation had decided upon an extension, and the amount now asked for was the estimated cost. Technical details were given by the electrical engineer (Mr. H. Talbot). There was no opposition.

Oystermouth.—The District Council have decided to advertise for tenders for the electric lighting of the district.

Paisley.—A committee has been formed for the purpose of inquiring into the advisability of acquiring and extending the tramways in the district. The Council have also approved of the bill of the Glasgow Corporation for the construction of electric tramways to and in the burgh of Paisley.

Poplar (London).—The District Board of Works have approved the electric lighting scheme prepared by their electrical engineer (Mr. A. Blackman). The total capital expenditure entailed is £79,000.

Plymouth.—It has been decided to make a uniform charge of 4½d. per unit for electric current to private consumers for lighting and power purposes.

Private Bill Legislation.—The bill deposited by the Central London Railway seeks an extension of time until June, 1900, for the completion of the railway.

The Liverpool Overhead Railway bill seeks powers to acquire on lease certain tramways authorised to be constructed by the District Councils of Waterloo-with-Seaforth and Great Crosby. When completed these tramways will form a continuous line from Great Crosby to the company's railway at Seaforth Sands. Powers are also sought to enter into working agreements with the Corporations of Liverpool and Bootle and other authorities. The new capital sought to be created is £50,000, with power to borrow a further £16,500.

The London, Walthamstow and Epping Forest Railway bill seeks to cancel the agreement with the Great Eastern Railway Co., and in lieu thereof ordinary general powers are sought to enter into working and traffic agreements with that company.

The Lancashire Electric Power Co. have deposited a bill for incorporating a company for the purpose of erecting stations for the production, storage and distribution of electricity. It is proposed to construct four stations, viz, in the parishes of Aspull, Parr, Little Lever, and on the Trafford Park estate, in the parish of Barton-on-Irwell. At these generating stations the company propose to manufacture and sell everything necessary for distributing energy for lighting and other purposes, public and private, and for converting the same into motive power, heat, or otherwise. The capital of the company is to be £3,000,000, in 300,000 shares of £10 each, but with power to divide these shares into preferred and deferred half shares. Power is also sought to raise a further £1,000,000 by the creation of debenture stock, but the compulsory powers of the company are not to be exercised until not less than £100,000 of the capital shall have been subscribed under contract. The first Directors are to be Messrs. W. P. J. Fawcus, F. E. Gripper, W. B. Hopkins, N. Scott Russell, G. B. Samuelson, R. P. Sellon (all of whom are, of course, well known in electrical if not in financial circles) *and four other persons to be nominated by them.* It is provided that nothing in the bill shall confer exclusive rights to supply energy within the area of supply, or to hinder or restrict any other body or person from supplying or increasing their supply within the same area, nor shall the company hereafter be entitled to compensation by reason of any competitive supply. The profits of the company are proposed to be limited to 10 per cent. on the paid-up capital, subject to a sliding scale.

The South Lancashire and Cheshire Electricity Co. have lodged a bill for similar powers. Only one generating station is proposed. This is to be erected at St. Helens. The capital is to be £750,000, with power to borrow a further £250,000. The clauses in this bill are almost identical with those of the Lancashire Company's bill.

The Leicestershire and Warwickshire Electric Supply Company's bill seeks powers to acquire land at Hinckley, Leicestershire, to erect a generating station for the supply of electricity direct or in bulk to any corporation within the company's area of supply. The share and loan capital is to be £1,000,000, of which £250,000 may be raised on mortgage. The profits are to be a fixed 10 per cent., but subject to an increase of 5s. per cent. for every one-tenth of a penny per unit at which energy may be supplied below 2½d. per unit.

The St. James' and Pall Mall Electric Light Co. has lodged a bill for powers to acquire additional lands for the erection of generating and transforming stations, to enable the Company to meet the increasing demand for electric current within its area of supply.

The Corporation of Birmingham have deposited their bill seeking powers to purchase the undertaking of the Birmingham Electric Supply Co. (Limited) under agreement. The sum of £420,000 is to be paid on Dec. 31, 1899, in respect of the company's fully paid-up capital of £200,000, wholly or partially, at the option of the company, either in cash or in 2½ per cent. Corporation stock. The transfer is to date as from Jan. 1, 1898, from which time to Dec. 31, 1899, the Corporation will, in addition to the sum of £420,000, guarantee a dividend at the rate of 6 per cent. per annum. The Corporation seek powers to borrow £500,000, to be repaid in 42 years.

The promoters of the Waterloo to Baker-street electric railway have submitted plans to the Vestry of St. Martin's-in-the-Fields for the construction of a subway for passengers from the north-east corner of Spring-gardens and Charing-cross to a point opposite the Grand Hotel, and thence to the south-east corner of Trafalgar-square, to communicate with a railway station to be constructed at Charing-cross. The vestry opposes the bill *pro forma*.

The Brompton and Piccadilly Circus Railway Co. seek powers to extend the already authorised line to St. Martin's-lane and Long-acre in one direction, and to the South Kensington station of the Metropolitan District Railway in the other. For these extensions £533,000 additional share and loan capital will be required. The bill proposes to empower the Metropolitan District Railway Co. to subscribe £200,000 towards the undertaking, to guarantee interest, &c.

Queenstown (Cork).—The Board of Trade have sanctioned the transfer of the Queenstown provisional order to the Cork Tramways and Electric Lighting Co. The town will probably be lighted electrically by Jan. 1, 1900.

Reigate.—The Town Council have purchased a site for an electricity generating station. Application is to be made to the Light Railway Commissioners for power to construct an electric tramway between Redhill Junction railway station and Reigate.

Rome.—The electric lighting installation at the Vatican is practically complete, and it is anticipated that current will be available in a few days.

Salford.—The Town Council are recommended to appoint Messrs. Lacey, Clirehugh and Sillar consulting engineers, at a fee of £500 per annum, in connection with the proposed extension of the electric light undertaking.

Sheffield.—In presenting the minutes of the Electric Light committee at the City Council, on Wednesday, Ald. Styring said the committee had taken possession of the undertaking of the Sheffield Company, and were sorry to find things were not in so satisfactory a condition as they could wish. To meet the demand for current it was necessary to work all the machinery to its full capacity. There was no spare machinery, and the management was absolutely dependent day by day on all the machinery keeping in good order. The late company had ordered additional machinery, but owing to the engineering strike this was only available two or three months ago. The failure of the electric light on Monday night was due to a short-circuiting behind the switchboard, and was entirely beyond the control of anyone connected with the undertaking. The lamps wired during the last year were 17,865, compared with 13,561 in the previous year, an increase of about 22 per cent. That brought up the total number of lamps to 73,853. The current sold during the year was 978,086 units, compared with 738,499 in the previous year, an increase of 32 per cent. Although the accounts for the past year were not completed, he was in a position to say that the gross revenue was £17,104. 15s. 4d., against £14,823. 10s. in the previous year, notwithstanding that current was in March last reduced from 5d. to 4d. The accounts were in an advanced enough state to show that there would be a sum of not less than £3,000 clear profit on revenue account for the Corporation as a result of the year's working.

Whitby.—The Board of Trade have notified the District Council that they will defer for another twelve months the question of rescinding the Whitby provisional order obtained in 1891.

Wimbledon.—For the position of resident electrical engineer, four candidates have been selected, viz:—Messrs. Ballard, Foyster, Harper, and Spencer. The final selection has been left with the Roads and Bridges committee.

The new gable at the electricity supply station was blown down by the gale on the 28th ult. The accident will delay the delivery of the machinery, the greater portion of which is ready.

Yeadon.—A special meeting of the District Council will be held to discuss the electrical proposals contained in the bill which is being promoted by the Yeadon and Guiseley Gas Co.

Soiree.—The annual soiree of the employés of the Sunbeam Lamp Co. (Limited), Gateshead, was held last week, when about 200 were present. In the unavoidable absence of the managing-director (Mr. Edmundson), the gathering was presided over by Mr. T. Grainger, secretary, and a very enjoyable evening was spent.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by Mr. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom all information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete Specifications. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

December 13, 1898.

26,380. E. GIGLIO. Liverpool. Improvements in electric batteries.
26,381. J. J. BATE. Liverpool. Improvements in conduits for electric conductors.
26,397. C. JUNG, A. BRECHER, and A. KITTEL. London. An improved acid-proof or non-conducting material for electrical and other purposes, and methods of preparing the same.*
26,401. C. E. SCHNÉE. London. Improvements in bath apparatus for treatment with electricity and medicinal substances.*

December 14, 1898.

26,412. J. STODDART. Halifax. An improved terminal for electrical fittings and apparatus.
26,419. H. HUMPHREYS and W. HUMPHREYS. Manchester. Improvements in and relating to dynamo electric motors.
26,420. C. M. DORMAN and R. A. SMITH. Salford. Improvements in fusible cut-outs.*
26,423. W. SHINN. Liverpool. An improved electrical governor for steam engines and the like.
26,458. R. RAINSFORD. London. Improvements in collectors for electric tramways on the overhead conductor system. (J. Walsh, United States.)
26,476. C. E. BURROUGHS. United States. Improvements in batteries.*
26,479. G. HOOKHAM. London. Improvements in electricity meters.

December 15, 1898.

26,494. A. WATSON. Birmingham. Improvements in electrical switches.
26,526. E. J. CLARK. London. A new or improved crucible for casting lead or like metals under pressure, especially applicable to the formation of secondary electric battery grids or plates.
26,527. H. H. LAKE. London. Improvements in regulators for electric car motors. (H. S. Maxim, United States.)
26,566. F. H. W. HIGGINS. London. Improvements in telephone transmitters.

December 16, 1898.

26,610. R. E. B. CROMPTON and E. A. N. POCHIN. London. Improvements in electric arc lamps.
26,614. J. A. MAYS. London. Process and apparatus for treating ores by electrolysis.
26,619. W. P. THOMPSON. Liverpool. Improvements in telephone switchboards or switching apparatus for telephone stations. (T. F. Ahern, United States.)*
26,649. SIEMENS BROS. AND CO. (LIMITED). London. Apparatus for simultaneously actuating from one point the controlling switches of the several electrical motor cars of a train. (Siemens and and Halske Aktien Gesellschaft, Germany.)*
26,650. — ANDREAS. London. Improvements in or relating to electric lamps.

December 17, 1898.

26,695. W. PUTTKAMMER. London. Improvements in electric accumulators or secondary batteries.
26,700. F. H. SNYDER. London. Improvements relating to the coating of metals with metals by the aid of electricity and to apparatus therefor.
26,703. H. T. HARRISON. London. Improvements in primary batteries.
26,723. W. E. BURNAND. London. New or improved device for indicating the frequency of an electric current or currents derivatively applicable for signalling and indicating speeds and the like.

December 19, 1898.

26,738. T. TAYLOR. Birmingham. Improvements in conduit inspection fittings for electric wiring.
26,769. H. E. ANDERSON. London. Improvements in and relating to electrically-operated clocks.*
26,787. H. G. TICEHURST and B. T. MOORE. London. Improvements in electric fuses for use in blasting or other like purposes.
26,789. V. I. FEENY. London. Improvements in and relating to electrical incandescent lamps. (Allgemeine Elektricitäts-Gesellschaft, Germany.)*
26,790. V. I. FEENY. London. Current conducting connection between electrical conductors. (Allgemeine Elektricitäts-Gesellschaft, Germany.)*

December 20, 1898.

26,806. W. B. THOMPSON. Dundee. Improvements in steam or electric after steering gear for ships.
26,807. F. L. MONKHOUSE. Newcastle-on-Tyne. Improvements in electric switches.
26,858. R. H. DUNN. Somerset. The oxidised-carbon electric power process.
26,886. THE POROUS ACCUMULATOR CO. (LIMITED) and J. C. HOWELL. London. Improved means for manufacturing metallic ribbon especially applicable for battery electrodes.*
26,914. A. COLLAVET. Liverpool. Improvements in dynamo electric machines, electric motors and the like.

December 21, 1898.

26,947. P. GADOT. Glasgow. A new process of treatment and method of working electric accumulators.
26,948. J. P. HALL. Manchester. Improvements in or relating to the brushes of dynamo electro motors and the like.
26,984. J. E. SPAGNOLETTI, J. CROOKES and J. LAWRENCE. London. An improved change-over switchboard and light indicator for use in connection with electric lights on board ship.
27,009. W. L. WISE. London. Interchangeable electric display apparatus. (G. L. Mason, United States.)

December 22, 1898.

27,018. C. H. LOGAN. London. An electro-chemical method of disintegrating rocks carrying minerals.
27,040. D. REID. Glasgow. An improved electric bell.
27,053. F. FOY. Manchester. Improved overhead electrical wire holder.
27,074. W. E. IRISH. London. Improvements in electrodes for arc lamps.*

December 23, 1898.

27,113. G. W. LAYBOURN. Tunstall. An improved process of the application of metals by electrolysis to or on the surface of earthenware, either in the biscuit or glost state.
27,142. W. A. BURNS. London. Improvements in or relating to electrically-driven ventilating fans.
27,183. A. SMITH. London. A new material for electrical insulation.

December 24, 1898.

27,254. C. WOOD. Birmingham. Improvements in electric arc lamps.
27,269. H. G. KUNKELMANN, E. C. FRANÇOIS and C. R. LOUBERG. London. Improvements in and connected with apparatus for measuring electricity.

December 27, 1898.

27,276. J. H. DORION. London. Improvements in supporting and take-up devices for cable-suspended electric lamps.
27,320. S. Y. HEEBNER. London. Improvements in and relating to electric motors and method of controlling same.*
27,334. P. M. JUSTICE. London. Improvements in telephone receivers. (A. T. Nye, United States).
27,335. P. M. JUSTICE. London. Improvements in telephone transmitters. (A. T. Nye, United States).
27,336. P. M. JUSTICE. London. Improvements in apparatus for use in telephone exchanges. (A. T. Nye, United States).

December 28, 1898.

27,360. J. THOMPSON. Cardiff. An apparatus or improved manner of means for determining or ascertaining the velocity of air currents in coal mines and other situations, and for other purposes by novel electrical and other means.
27,390. C. D. ABEL. London. Improvements in coin freed apparatus for electric and fluid meters. (Société Anonyme Continentale Pour la Fabrication des Compteurs a Gaz et Autres Appareils, France).

December 29, 1898.

27,414. J. CLARK. Glasgow. Improvements in or relating to electric lamp bracket joints.
27,453. H. LEITNER. London. Improvements in electric motors.

December 30, 1898.

27,469. S. O. COWPER-COLES. London. A process for the electro-deposition of vanadium.
27,473. D. STEWART AND CO. (LIMITED) and T. D. SEATON. Glasgow. Improvements in graduated resistance apparatus for starting on reversing electro motors.
27,498. G. ZAHIKJANZ. London. Improvements in electric incandescent lamps.
27,526. J. MATTHIAS. London. Improvements in thermo-electrical building bricks or blocks.*

December 31, 1898.

27,556. R. BOTTELLI. Italy. Improvements in incandescent electric lamps.
27,564. J. S. STEVENS, C. G. MAJOR and E. C. STEVENS. London. Improvements of controlling apparatus for electric lifts and other machines.
27,577. W. A. CROWDUS. London. Improvements in motor-driven vehicles and in electric motors therefor.
27,583. F. S. WORSLEY. London. Improvements in electric arc lamps.
27,586. E. EGGER. London. Improved direct coupled driving arrangement for electric automotors.
27,592. THE BRITISH THOMSON-HOUSTON CO. (LIMITED). London. Improvements in controllers for electric motors. (W. B. Potter, United States.)*

SPECIFICATIONS PUBLISHED.

NOTE.—All Specifications can now be obtained at the uniform price of 8d. each.

1897.

27,428. RIANT. Electric furnaces for the production of calcium carbide and other substances.
27,508. MARCH. Extraction of gold by electrolysis.
27,619. NORDMANN. Incandescent electric lamps.
28,157. HOPE-JONES. Relay applicable to pneumatic or electric organs, or to other apparatus.
28,259. DUNCAN STEWART and CO. (LIMITED) and LYON. Resistance and contact apparatus for electric currents.
28,457. HIGGINBOTTOM, HINDLE, and MANNOCK. Apparatus for regulating and controlling electric motors.
28,729. BOOTH. Electrical switches.
29,009. BASTICK and THORNTON. Electric furnaces for the production of calcium carbide and other substances.

Digitized by Google

29,010. Bastick and Thornton. Means or apparatus for conveying the boxes to and from electric furnaces.
29,011. Bastick and Thornton. Electric furnaces for the production of calcium carbide and other substances.
29,116. Baynes. Distribution and regulation of electric energy, and conductors connected therewith.
29,251. Wade and The Electric Motive Power Co. (Limited). Connections for storage cells.
29,318. Wade and The Electric Motive Power Co. (Limited). Control and regulation of electrically-propelled vehicles.
29,361. Kerridge. Electric gas lighting and controlling devices.
30,001. Luyers. Railway aero-electric brakes.
30,037. Lacko. Electric arc lamps. (Date applied for under International Convention, July 21, 1897.)
30,470. Jones. Electricity meter, self fixing, or box and main connection board, or box combined.
30,572. Fowler and The Mutual Electric Trust (Limited). Joints for electricity conductors.

1898.

468. Rosling and Appleby. Enclosed motors or dynamos.
586. P. R. Jackson and Co. (Limited) and Lewis. Mounting of dynamo electric machines.
632. Walters. Electric lamps and switches.
698. De Szwantowski. Electric illumination of railway trains.
812. P. R. Jackson and Co. (Limited) and Lewis. Dynamo electric machinery.
1,021. Stearn. Manufacture of filaments for incandescence electric lamps.
1,628. Crowdus. Secondary batteries.
1,687. Thompson. Electric signalling apparatus.
1,826. Cutter. Electric switches and cut-outs.
2,167. Moores and Farrell. Electric generators for cycles and other vehicles.
2,427. R. Waygood and Co. (Limited) and Unwin. Variable electric resistances or rheostats.
2,479. Byng and Bevis. Terminals for electrical connections especially adapted to incandescence lamp holders.
2,684. Fisher, Round, Round and Round. Apparatus for the electro-deposition of metals.
3,204. Vigreux and Brillié. Electric arc lamps.
3,749. Rhodin. Method of oxidation and bleaching by means of electrolysis.
5,172. Collingwood. Telephone transmitters.
5,663. Middleton and Huggins. Metallic conductors for protecting electric wires and cables.
6,901A. Weston. Index needles or pointers for electrical and other indicating or measuring instruments. (Date claimed under Patents Rule 19, March 22, 1898.)
6,991. Weston. Electrical measuring instruments.
7,057. Proctor and Blaikie. Plug switches and plug connections for the control and distribution of electric currents.
10,608. Lake (Hoffmann). Electrically illuminated buoys.
15,040. The British Thomson-Houston Co. (Limited). (Hewlett). Automatic circuit breakers.
16,245. Buckley and Croffert. Electric sounding device.
16,716. The British Thomson-Houston Co. (Limited). (Rice). Systems of control for electrically-propelled trains.
17,592. Bugg and Darling. Portable electric lamps.
18,156. Vogt. Manufacture of electrical resistances.
18,231. Bachmann, Vogt, Weiner, König, Kirchner and Jörg. Electrical heating appliances formed of artificial stone.
18,232. Bachmann, Vogt, Weiner, König, Kirchner and Jörg. Electrical resistances of artificial stone composition.
18,740. Siemens Bros. and Co., Limited (Siemens and Halske Aktiengesellschaft). Safety fuse apparatus for electrical installations.
19,537. Burke. Dynamo electric machines.
19,938. The British Thomson-Houston Co. (Limited). (Hewlett.) Safety devices for dynamo-electric machines.
19,942. Mills (Whitfield and Cowan). Combined electric generator or motor and steam, air, or the like engine or compressor.
20,049. Wise (Actien-Gesellschaft Elektricitaetswerke, vorm. O. L. Kummer and Co.). Electric safety fuses.
20,202. Ducousse. Electrical apparatus for operating railway points and signals. (Date applied for under International Convention, Feb. 24, 1898.)
20,416. Johnson (Hutchins). Means for supplying current to electrically-propelled railway vehicles.
20,677. Bullock. Apparatus for starting electric motors.
20,989. Bickford-Smith. Compositition for electrically firing detonators.
21,046. The British Thomson-Houston Co. (Limited). (Davis). Electric meters for alternating current circuits.
21,047. The British Thomson-Houston Co. (Limited). (Emmet.) Electric fuses.
21,048. The British Thomson-Houston Co. (Limited). (Allo). Prepayment electric meters.
21,410. Hutchison. Controlling switches and apparatus for electric motors.
21,943. Haddan. (The Allegemeine Electricitäts Gesellschaft.) Electrical contact breakers.
21,947. Siemens Bros. and Co. (Limited) and Holmes. Electric winch suitable for ash hoists and such like appliances.
22,080. The British Thomson-Houston Co. (Limited). (Hewlett). Protecting static volt meters.
22,082. The British Thomson-Houston Co. (Limited). (Geisenhoener). Trolley cars for electric railways.
22,085. Myers. Conductors and collectors for electric railways,
22,153. Carter. Gauge for testing if stereo, electro, photo-process, and such like blocks are type-high and uniform in thickness and for other like purposes.
22,171. Graeber and Tobler. Insulating devices for the electrodes of accumulators.
22,461. Johnson (Dercum). Primary batteries.
22,600. The British Thomson-Houston Co. (Limited). (Painter.) Incandescent electric lamps.
22,601. The British Thomson-Houston Co. (Limited). (Spinney.) Electric arc lamps.
22,664. Munro, Brecknell and Rogers. Appliances for use in securing the copper bonds or conductors in electric tramway rails.
22,683. The British Thomson-Houston Co. (Limited). (Case.) Coupling for electric conductors.

COMPANIES' MEETINGS AND REPORTS.

Eastern Telegraph Co. (Limited).

The following report of the Directors for the half-year ended Sept. 30 last will be presented to the fifty-third half-yearly ordinary general meeting of proprietors, at Winchester House, London, E.C., on Jan. 19, at 1 o'clock:—

The revenue amounted to £444,011. 12s. 3d., from which are deducted £121,376. 13s. 11d. for ordinary expenses and £41,716. 16s. 6d. for expenditure relating to repairs and renewals of cables, &c., during the half-year. After providing £2,522. 17s. 2d. for depreciation of spare cable, £6,965. 8s. 2d. for income tax, there remains a balance of £271,429. 16s. 6d., to which is added £3,568. 7s. 11d. brought forward—total, £274,998. 4s. 5d. From this balance there has been paid—

Interest on Debentures and Debenture Stock.....	£29,855	10	9
Dividend on Preference shares	10,148	2	1
Dividend on Preference stock	14,547	11	0
Two interim dividends of 2s. 6d. per share each on the Ordinary	100,000	0	0
	£154,551	3	10

After carrying £10,000 to reserve for maintenance ships, £5,000 to reserve in connection with the removal of head offices, and £70,000 to general reserve, there remains £35,447. 0s. 7d., which is carried forward. The revenue includes £23,901. 13s. 3d. dividends for the half-year upon the company's shares in other telegraph companies.

The new issue of £500,000 3½ per cent. Preference stock was more than fully subscribed for by the shareholders. One section of the cable, for which this amount is principally required, has been laid from Porthcurnow to Gibraltar, and the expedition with the additional cables from Gibraltar to Malta and Alexandria left the Thames on the 27th ultimo.

The conversion of the Ordinary shares into Ordinary stock, authorised at the last general meeting, was effected on Nov. 1. Shareholders who have not yet exchanged their share certificates for the new stock certificates are requested to do so without delay. The Stock Exchange Committee has granted official quotations for the new stock and for the additional issue of 3½ per cent. Preference stock.

The Directors are arranging for the building of a new cable repairing steamer to replace the ss. "John Pender," recently sold.

NEW COMPANIES, STATUTORY RETURNS, &c.

JOSEPH BOOTH AND SONS (LIMITED).—This company was registered on Jan. 9, with a capital of £75,000, in £100 shares, to acquire the business now carried on under the style of Joseph Booth and Sons, and to carry on the business of engineers, crane manufacturers, machinists, founders, electricians, and suppliers of electricity for the purposes of light, heat, motive power and otherwise. The first Directors are:—John W. Booth, William Booth, Arthur Booth and John A. Booth.

ENGINEERING AND ELECTRIC WORKS CO. (LIMITED).—This company was registered on Jan. 9, with a capital of £5,000, in £1 shares, to carry on the business of general engineering contractors, electricians, mechanical and electrical engineers, suppliers of electricity, and manufacturers of and dealers in electrical apparatus, and to construct, lay down, fix and carry out all necessary cables, wires, lines, &c.

LEECOLL ELECTRIC BATTERY CO. (LIMITED).—This company was registered on Jan. 5, with a capital of £60,000, in £1 shares, to acquire and develop Patent No. 10,439, (1897), and any subsequent improvements therein, to manufacture, sell and deal in lamps, primary and secondary electric batteries, vehicles, carriages, motor cars, motors, &c.

NUNEATON AND DISTRICT LIGHT RAILWAY CO. (LIMITED).—This company was registered on Jan. 5, with a capital of £2,000, in £1 shares, to apply for Orders for the construction and working of a light railway in Nuneaton, Warwickshire, and its neighbourhood, and to construct, equip, maintain and work railways and tramways by electricity or other motive power

AFRICAN TRANSCONTINENTAL TELEGRAPH CO. (LIMITED).—The annual return to Dec. 28 has been filed. The capital is £300,000, in £1 shares, of which 154,980 have been taken up. The full amount has been called.

Digitized by Google

HOWELL'S SIMPLEX ANTI-INDUCTIVE TELEPHONE SYNDICATE (LIMITED).—The statutory return to Dec. 13 has been filed. The capital is £12,000, in 11,950 Ordinary shares of £1 each, and 1,000 Deferred shares of 1s. each. 2,840 Ordinary and 176 Deferred shares have been taken up, and the full amount has been called.

RIVER PO ELECTRIC AND POWER SYNDICATE (LIMITED).—The statutory return to Nov. 12 gives the capital as £10,000, in £1 shares (of which 1,000 are Deferred). Seven shares have been taken up and paid for in full.

CITY NOTES.

MEMORANDA.—Bank rate 4 per cent. (since Oct. 13, 1898). Price of silver 27 5/16d. per oz. (Jan. 12). Consols (2¾ per cent.) 110 7/8—111 for money, 111—111 1/16 for account; 2½ per cent. 103½—104 (Jan. 12). Stock Exchange Settling Days: Stocks and Shares Continuation Days, Jan. 25 and Feb. 8; Ticket Days, Jan. 26 and Feb. 9; Pay Days, Jan. 13 and 27; Mining Share Carry over Days, Jan. 24 and Feb. 7.

BLACKPOOL AND FLEETWOOD TRAMWAY CO.—It has been decided to issue £30,000 new ordinary capital in shares of £10 each to rank *pari passu* with the existing shares. The new issue is rendered necessary, on account of the success of the line, and to allow of further developments. Although the line has only been open five months, the receipts for the half-year will, it is stated, permit the payment of 8 per cent., and leave a substantial balance.

DIRECT UNITED STATES CABLE CO. (LIMITED).—An interim dividend of 3s. per share, free of tax (being at the rate of 3 per cent. per annum), for the quarter ended Dec. 31, will be payable on and after the 31st inst. The Directors have set aside £12,000 to reserve, and carry forward about £5,920. The transfer books will be closed from 17th to 31st inst. inclusive.

ELECTRIC CONSTRUCTION CO. (LIMITED).—The transfer books of the Four per Cent. Perpetual First Mortgage Debenture stock of this company are closed to the 14th inst.

GENERAL ELECTRIC CO. (OF AMERICA).—This company has declared a dividend on the Preferred stock of $1 1/2, payable Jan. 31.

HAMPSTEAD ELECTRIC SUPPLY CO. (LIMITED).—The transfer books of the Preference shares of this company are closed to 27th inst.

NEW ITALIAN ELECTRIC CO.—The business of Messrs. Gadda and Co., electrical engineers, Milan, has been turned into a limited liability company, with a capital of 2,000,000 lire.

STOCK EXCHANGE NOTICES.—Application has been made to the Stock Exchange Committee to appoint a special settling day in and to grant a quotation to 13,334 Ordinary £10 shares and 20,000 £10 Five per Cent. Cumulative Preference shares of the *Potteries Electric Traction Co. (Limited)*. The committee has also been requested to allow the further issue of £10 shares of the *Brazilian Submarine Telegraph Co. (Limited)*, and the further issue of 150,000 Four per Cent. Debenture stock of the *Edison and Swan United Electric Light Co. (Limited)* to be quoted in the Official List.

SVENSKA AKTIEBOLAG SIEMENS AND HALSKE.—This is the title of a company formed in Stockholm, with a capital of 300,000 kroner, to carry out electrical undertakings in Sweden.

TELEGRAPH MANUFACTURING CO. (LIMITED).—The shares of this Company have been granted an official quotation by both the London and Liverpool Stock Exchanges, and are now regularly quoted in the Official Lists.

WEST INDIA AND PANAMA TELEGRAPH CO. (LIMITED).—The estimated amount of the traffic receipts of this company for the half-month ended Dec. 31 is £2,367, against £2,205 in the corresponding period of 1897.

NOTES.

THE new map of electric supply undertakings in the United Kingdom, which we publish as a Supplement this week, shows at a glance the distribution of these undertakings throughout the country. The circles and squares of red and blue, strangely intermingled, indicate by their shape the distribution of company and municipal undertakings, and by their colour that of alternating and continuous-current systems. In a former edition of this map we found it necessary to introduce a special inset map of the London stations, owing to the great and increasing density in this district. The Black Country, from a similar cause, threatened to belie its name and not only to become an incoherent chromatic effect, but to do violence to geography by overcrowding and displacement. We have therefore removed that sooty territory to a second inset map, which has found a convenient place in the, electrically speaking, uncultivated regions of north-west Scotland. We hope that the Supplement in its latest guise will prove of even greater utility than its predecessors.

THE prompt selection of a successor to Sir SPENCER WALPOLE as Secretary to the Post Office will have the good effect of silencing a good deal of irritating discussion which was springing up in respect of the various claimants to the vacant Secretaryship. The appointment of an outsider is quite in accordance with precedent. Sir ARTHUR BLACKWOOD left the Treasury to become Financial Secretary to the Post Office by way of preliminary to his succeeding Sir JOHN TILLEY, who was then approaching the eve of his retirement. Mr. WALPOLE's appointment was a still more conspicuous example of the same procedure, his previous position—that of Lieutenant-Governor of the Isle of Man—having no relation whatever with the postal service. This important appointment is practically in the gift of the Treasury, and we make no doubt that in selecting Mr. MURRAY his antecedents and progressive views have been duly considered by that autocratic body. The funny thing is, that the offer is reported as having been "accepted in deference to the special request of Her Majesty's Government."

PLYMOUTH, Devonport, and Stonehouse are three towns situated so near together as to form a sort of municipal galaxy. In the matter of electrical supply, Plymouth has been foremost, though its long-delayed municipal power station is still uncompleted. A municipal electric supply system is now projected at Devonport, but there are difficulties in the way, principally connected with the choice of a suitable site for the power station. It seems to us that these three towns afford an admirable arena for a trial of the capacity of local authorities to combine together and run a generating station for supply "in bulk." The area is not as yet coveted by any projected company, and evidence of genuine intention on the part of these local authorities might go far towards simplifying the present difficulty in connection with undertakings for wholesale supply. But if it is impossible for two large and closely related towns, like Plymouth and Devonport, to combine their electricity undertakings, what *locus standi* have municipalities in their opposition to companies who are willing to do this sort of thing in other parts of the country?

AT the monthly dinner of the London Chamber of Commerce on Tuesday evening the subject proposed for discussion was "The Progress of Electricity." The Chairman of the Council, Mr. T. F. BLACKWELL, who occupied the chair on this festive occasion, introduced the subject in general terms. He advocated the all-British cable scheme, nationalisation of the telephone system, and greater encouragement of electrical enterprise on the part of the legislature. Mr. SYDNEY MORSE, the chairman of the Electrical Trades' Section, followed up the protest against the excessive restrictions of legislation, and said that Parliamentary Committees had "scotched" electrical progress instead of encouraging it.

MAJOR-GEN. WEBBER was very unhappy because of the resolution of the Chamber in favour of the nationalisation of the telephone system. That resolution. he feared, "would

Digitized by Google

be likely to kill the telephone industry in this country"—a compliment to the resolution, if a calamity to the industry. The MAJOR's theory is that the telephone business is purely local, and he alleges that to treat it on a national basis would be disastrous. We all remember his scheme of village telephony, in which the exchanges were to be placed near the Board schools, and the little boys and girls were to be sent out to hunt up an inhabitant whenever he might be "called." If it is such a system as this the MAJOR objects to regard as national, we agree with him; in fact, we hope its realisation in this country may never be even local. For the rest, we repeat our oft-made assertion that the one proper basis for an effective telephone system is that of Government control.

Cable Interruptions.—

	Date of Interruption.
Para—Maranham	Nov. 15. 1898

Energy in Radio-Active Bodies.—A Paper on this subject was read last Monday before the Académie des Sciences at Paris, by Sir William Crookes, F.R.S.

Royal Society.—Among the Papers down for reading yesterday was one by Prof. K. Pearson, F.R.S., and Miss Lee, "On the Vibrations in the Field round a Theoretical Hertzian Oscillator."

The Congo Telegraph.—The Brussels correspondent of the *Standard* learns from an official source that the telegraph line now being laid alongside the Congo River has reached Lukolela, nearly 500 miles from the starting point of the line at Boma.

Municipal Corporations and the National Telephone Co.—At a meeting of the Municipal Corporations Association, held at the Westminster Palace Hotel on Thursday last week, the National Telephone Co.'s three bills were discussed. It was said that if these bills were passed by Parliament they would have an injurious effect on municipalities, and that it was preposterous to allow to be passed a scheme which was designed merely in order that the Telephone Company could, when its licence expired, claim an enormously enhanced value for its property. A resolution was passed to the effect that every possible step should be taken to oppose the measures.

Appointment.—The Duke of Norfolk has offered the Secretaryship of the Post Office, about to be vacated by the retirement of Sir Spencer Walpole, K.C.B., to Mr. George H. Murray, C.B., now chairman of the Board of Inland Revenue. Mr. Murray has accepted the appointment in deference to the special request of Her Majesty's Government. Mr. Murray entered the Foreign Office in 1873, and was transferred to the Treasury in 1880. He was private secretary to Mr. Gladstone in 1892-94, and to Lord Rosebery in 1894-95, when they filled the office of Prime Minister. Mr. Murray succeeded Sir Alfred Milner as chairman of the Board of Inland Revenue in 1897.

Interruptions to Supply.—*Sheffield.*—On the 9th inst., when four alternators of a total capacity of 1,500 kilowatts were running in parallel in the Sheffield central station, one of the machine fuses on the switchboard melted without warning. This set up an arc across the fuse terminals, and immediately afterwards the remainder of the machine fuses melted and two additional arcs were started on the switchboard. This lasted 20sec., until all steam could be shut off and the field and other switches opened. Afterwards a number of fires, caused by the ignition of resin oil and sulphur, had to be extinguished with the aid of sand and canvas cloths. There was a stoppage of the entire system for 7min., then current could be supplied to a large portion of the central area. As soon as the respective alternators could be tested, the remainder of the circuits were connected up in succession, and the supply was completely re-established in 40min.

Stratford.—On Wednesday night a failure of the supply caused the extinction of all the lamps in the Broadway, Stratford.

Personal.—We are informed that Mr. E. C. Rimington has recently taken over the testing and consulting work formerly carried on by Messrs. Harrison and O'Brien, at 19 and 21, Queen Victoria-street, London, E.C. Mr. Rimington is making a speciality of investigating and reporting on new inventions and apparatus, the standardising of high grade instruments (especially for alternating work), the determining of efficiency of lamps and accumulators, and exact testing of transformer iron insulating materials, &c., for manufacturing firms. For these purposes the laboratory at the above address is well furnished with complete sets of special instruments, and the well-known ability of Mr. Rimington, who will be remembered by many former pupils as senior lecturer at the School of Electrical Engineering, Hanover-square, as well as for his experimental work and frequent contributions to technical literature, will offer a guarantee that all work entrusted to him will be carried out in a thoroughly efficient manner. We are glad to be able to mention that Mr. Hadyn J. Harrison will continue to render his advice and assistance.

Institution Premiums.—At the last meeting of the Institution of Electrical Engineers the following were announced as the winners of the various premiums for the session 1897-8:—The Institution Premium: Mr H. F. Parshall, for his Paper on "Earth Returns for Electric Tramways"; the Paris Electrical Exhibition Premium: Mr. Robert Hammond, for his Paper "The Cost of Generation and Distribution of Electrical Energy"; an extra Premium to Mr. L. Andrews for his Paper on "The Prevention of Interruptions to Electricity Supply." The Premium for original communications has been awarded to Mr. H. N. Allen for "Sparkless Reversal in Dynamos." Senior Students' Premium: J. M. Donaldson for his Paper on "Notes on the Dover Tramways"; Second Students' Premium: M. Solomon for his Paper on "Hertz Waves and Wireless Telegraphy"; Third Student's Premium: E. E. Tasker, for his Paper on "Alternate Current Motors"; and "Sir David Salomons" scholarships to Mr. Tom Rolls Renfree (King's College) and Mr. H. J. Tomlinson (University College, London). The "Fahie" Premium has not been awarded, as no telegraphic or telephonic Papers were submitted during the Session.

Wireless Telegraphy to the East Goodwin Lightship.—We are now able to give further particulars in reference to the experiments made by the Wireless Telegraph Co. between the South Foreland lighthouse and the East Goodwin lightship, already alluded to in our issue of December 23rd and in Capt. Brett's remarks at the Institution of Electrical Engineers last week. Permission was granted by the Trinity House authorities for the Company to make use of either the East Goodwin, the Gull-stream, or the South Sand-Head light vessel—the land station to be at the South Foreland lighthouse—and they chose the furthest off of these light vessels, namely, the East Goodwin lightship, which is 12 miles distant from the South Foreland lighthouse. All the apparatus was brought on the lightship in an open boat and rigged up in the course of an afternoon, and on Christmas Eve the lightship and lighthouse were placed in perfect telegraphic communication. Many messages passed on that day, and there has not been the slightest hitch from the starting of the installation to now, every message sent from either shore or ship being perfectly received at the corresponding station. Although the weather has been most tempestuous since the instruments were installed, they have not been in the slightest degree affected.

The Wear of Steel Rails.—In a Paper on "The Effects of Wear upon Steel Rails," read last Tuesday at the Institution of Civil Engineers, by Mr. William G. Kirkaldy, the author recounted how experiments he had carried out on two steel rails which had broken under traffic had led to his devoting special attention to the subject and to a wider investigation. It was found that the breakage of rails resulted from failure commencing at the top surface, and not from the bottom, as appeared to be the usual belief, and that the deterioration was confined entirely to the top or running head. The deterioration was of the nature of a mechanical hardening of the surface under the action of the rolling load. In some cases this hardening further developed into a species of disintegration by the formation of minute

* In calculating this [illegible]

Digitized by Google

transverse cracks, which, by gradual deepening, ultimately resulted in failure, unless the rail was removed in time. A description was given of the tests specially devised for ascertaining readily, and in a practical form, the extent of deterioration in worn rails. Briefly, this consisted in bending the rail in reverse directions and comparing the behaviour It was explained that as the bottom member of a rail was found to be undeteriorated in quality by wear, it became possible to determine very closely the original quality of any rail (apart from the loss of substance) by testing it under bending stress in the normal direction—that was, keeping the worn head in compression—also by testing specimens, prepared from the bottom member, under tensile stress. If no deterioration was present, the rail, when bent with the worn head in tension, would bend to a degree corresponding with its behaviour with the worn head in compression. To illustrate this, examples were given showing the wide divergence in some worn rails between their original properties, as brought out under the normal direction of bending, and their behaviour when the direction of test was reversed. The leading features were illustrated by diagrams. A few representative rails taken from under various conditions of service were referred to. On the one hand, in the case of a rail after being subjected to severe brake action, the deterioration was very clearly marked; while on the other hand, in the case of a rail that was under favourable conditions, although after the exceptionally long life of 23 years' main-line service, the deterioration was very slight. The author drew special attention to the significance of this latter rail. From the commencement he refrained from taking an alarmist view of the condition of rails, considering that where failures or breakages had occurred, there would be definite and special causes sufficient to account for them. He anticipated that the great bulk of rails, where under favourable conditions as to service, would not necessarily be found in a bad state. Reference was made to a number of other rails found to remain in excellent condition after various lengths of service up to considerable periods of time. Striking instances of very severe and rapid deterioration, accompanied with the development of induced flaws, were mentioned, illustrated with figures reproduced from the original reports. The following questions suggested themselves in dealing with this subject: (1) Did all rails suffer alike as to the nature of the deterioration? (2) Did not the quality of the steel affect the resistance of rails to deterioration? (3) Did not the commencement and progress of deterioration of any rail depend on, and vary greatly with, the nature of the traffic, but still more on the special conditions due to its situation?

Experiments in Hertzian Telegraphy.—Herr K. Strecker, whose previous experiments in Hertzian telegraphy we have noted (see *The Electrician*, Vol. XL., pp. 780 and 791), gave an account of some further work in the same direction in a Paper read before the Berlin Elektrotechnischer Verein on November 22nd last. His object was to study the conditions under which one could work with long horizontal wires in place of vertical conductors, in view of the greater convenience in erecting and maintaining the former. Prof. Slaby had in his experiments, using wires 100 metres long and stretched 2 metres above the surface of the ground, succeeded in transmitting distinct signals over a distance of 3 kilometres. In the present experiments, conducted at Müggelsee, some 12 miles from Berlin, Herr Strecker used an induction coil with a 50cm. spark and a motor-driven mercury interrupter breaking the primary circuit 20 times per second. Signals were made with a Morse key having carbon contacts, placed in the primary circuit of the induction coil. The radiator consisted of four zinc spheres placed vertically above one another, the two inner ones having a diameter of 20cm., and being placed 1mm. to 3mm. apart in castor oil, while the outer ones were 2·3cm. in diameter and placed some centimetres away from the larger spheres. Various types of coherer were tried, some of brass filings, some of nickel filings and others a mixture of both. There appeared little to choose between them, except that it was necessary to oxidise the nickel filings slightly. The electrodes were small cylindrical pieces of brass, or strips of silver, placed usually some 2mm. or 3mm. apart. In order not to bring the interrupter of the tapper too near to the coherer, an electromagnetic tapper without an interrupter was used at the coherer itself, the magnet being in series with the magnet of a tapper of the usual form. The relay in the coherer circuit was on the d'Arsonval principle, and sensitive enough to work with a tenth of a milliampere; it had a resistance of 200 ohms, and an E.M.F. of 0·1 volt was employed in the circuit. The connections were similar to those described in Herr Strecker's previous paper, with the exception that another relay was interposed between the d'Arsonval relay and the one in the permanent current circuit, this additional relay being bridged by a resistance. The wires connected to the transmitting and receiving apparatus were 100m. long and parallel to one another, the distance between them being 5·7km. Bronze wire, supported on ordinary telegraph poles and insulators, was employed, that at the transmitting end having a diameter of 4·5mm, and being 9·6 metres above the surface of the ground that at the receiving end 2mm. diameter, and 8·4 metres above the ground. There were no obstacles between the wires. Several wires were connected in parallel, but the experiments did not show whether or not this was an advantage. The transmitting station was on a hill about 800 metres from the eastern end of the lake, and the receiving station on an elevation at the western end, and behind each conductor was a pine wood. It should also be mentioned that the two stations were telephonically connected by an overhead line running round one side of the lake. One end of the transmitting line was connected to the radiator, the other end was insulated and the other terminal of the radiator was earthed. The coherer had one terminal earthed, and the other connected to the receiving wire, whose far end could either be earthed through a condenser of 0·24 microfarad or insulated. The former connection unexpectedly gave the better result, and by increasing or decreasing the capacity the results were less good, thus indicating resonance. In spite of wet weather and difficulties in keeping the apparatus dry, the experiments, which were continued for some weeks, were on the whole successful, distinct signals being received; but the Morse signals were somewhat long, and, in consequence, the transmission was very slow. Several modifications in the arrangements were made—*e.g.*, putting the coherer in the middle, instead of at the end of the line, and increasing the length of the receiving line to 300 metres; but these did not occasion any marked improvement. Herr Strecker concludes that the tests have shown that, employing ordinary telegraph stores, and horizontal in place of vertical wires, signals can be transmitted through a distance over 50 times the length of the wires.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-day) FRIDAY, January 20th.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Liquid Hydrogen," by Prof. Dewar, F.R.S.

SATURDAY, January 21st.

INSTITUTION OF JUNIOR ENGINEERS.

3:30 p.m. Visit to the Streatham Hill Depôt of the Brixton Cable Tramway.

TUESDAY, January 24th.

NORTHERN SOCIETY OF ELECTRICAL ENGINEERS.

8 p.m. Meeting at the Albion Hotel, Manchester. Paper to be read: "Electric Traction," by H. F. Parshall.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Papers for further discussion: (1) "The Effects of Wear upon Steel Rails," by W. C. Kirkaldy; (2) "On the Microphotography of Steel Rails," by Sir W. Roberts-Austen, F.R.S.

WEDNESDAY, January 25th.

INSTITUTION OF ELECTRICAL ENGINEERS.

7:30 p.m. Students' Meeting in the Library of the Institution, when there will be a discussion on "Systems of Electric Traction."

THURSDAY, January 26th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting, when the following Papers, which will be taken as read, will be discussed: (1) "Rules for the Regulation of the Wiring of Premises for Connection to Public Supply Mains," by J. Pigg; (2) "The Regulation of Wiring Rules," by C. H. Wordingham; (3) "The Institution Wiring Rules," by R. E. Crompton.

THE ELECTRIC LIGHTING OF GIBRALTAR.

Following the example of Malta, Singapore and other Crown Settlements, Gibraltar has recently inaugurated a complete system of public and private electric supply, chiefly for lighting purposes. This has been carried out to the designs and under the direction of Mr. A. H. Preece. The site selected for the power station is known as the King's Bastion, and is probably one of the best protected spots on the Rock. It was originally an artillery barracks, and, being built on the solid rock, considerable difficulty was experienced in the excavations necessary to adapt the forti-

fication to the purpose of an electric light station. Some idea of the work that has been done in this direction may be gathered from the accompanying illustrations and scale drawings. The station buildings consist of a double lean-to structure, built on three different levels, viz.: Firstly, the old level of the barracks; secondly, a lower level for the engine room and casemates; and, thirdly, a still lower level for the boiler house, the latter at about sea level. The buildings, which have been admirably adapted to their present purpose, were erected by the Colonial Engineering Department, which has not omitted to provide accommodation for considerable extensions of the plant when such may become necessary.

The general arrangement of the machinery in the King's Bastion is sufficiently indicated by the accompanying plans. The station is at present equipped with three locomotive boilers, feeding through a system of steam mains four

have had to be surmounted in arranging for a supply of feed and circulating water.

From this station four feeders radiate to the distributing network in the town, and these feeders are worked at the

supply, and the 220-volt 3-wire network for the street lighting, which is effected principally by means of Ediswan glow lamps of from 8 to 32 c.p. The capacity of the complete station is 10,000 (16 c.p.) lamps, and there are at present 500 lamps of various candle-power in use for the street lighting. The street lamps are arranged so that alternate lamps are on opposite sections of the 3-wire network, and at midnight one or other of the sections is switched off, thus reducing the consumption by one-half. This switching is done at the sub-stations. Among the public buildings supplied are the Barracks, the "Convent" or Governor's House, and the hospital. Ultimately all the fortifications

will be wired and fitted both for general lighting and for a number of search lights.

The electric supply system, as above described, was carried out by Mr. A. H. Preece, with the assistance, on the spot, of Mr. M. S. Chambers, who has brought to the work the extensive and special experience he acquired in undertaking similar work at Malta and other places. It should be mentioned that the whole of the construction work has been carried out exclusively with native labour, and that these men had to be trained for the work by the Colonial Department under Mr. Chambers' guidance. The wiring of most of the buildings through the solid rock, and the special switching arrangements rendered necessary thereby, has made the work more than usually arduous—and interesting from an engineering point of view. The arrangements for a good supply of circulating water have been especially well designed and carried out. The station was put in operation for the first time on Christmas Day last year. We give below some more detailed particulars of the various departments of the undertaking:—

Boiler House.—As shown in the illustration, the boilers are erected in a building at the back of the original casemates. There are three locomotive boilers, built by Messrs. J. Penn and Sons, of Greenwich, each boiler having a heating surface of 1,300 sq. ft., a grate area of 32 sq. ft., and works at 150lb. pressure. With cold feed and burning the hand-fired Welsh coal, as is now done, an evaporation of 6,000lb. of water per hour is readily accomplished. The boilers occupy one-half of the boiler house, the other half being occupied by the feed pumps, leaving extension space for two additional boilers. The feed pumps, two in number, have a pumping capacity of 4,000 gallons per hour. They are of the duplex direct-acting steam-driven type. A large storage tank just outside the boiler house has been constructed to take the water of three catchments which originally supplied water to the barracks. In addition to this supply, there are two feed-make-up evaporators used in conjunction with the condensing plant. For the condenser circulation salt water is used; and it is thus necessary to evaporate and condense for the feed-make-up. One of these feed-make-up evaporators, built by Mr. Joseph Wright, of Tipton, is shown in an accompanying illustration.

Machinery Casemates.—There are four casemates at present in use, two of these being for the main generating machinery, one for the condensing and feed-make-up plant, and the remaining one for the switchboard. In the machinery casemates there have been erected four direct-coupled Belliss-Siemens high-pressure alternators—viz., two of 100 kilowatt capacity, one of 50-kilowatt capacity, and one of 20-kilowatt capacity. Each generator carries its own exciter on an extension of the alternator spindle. The engines are of the usual well-known enclosed vertical type adopted by Messrs. Belliss and Co. The largest engines run at 380 revolutions per minute, the intermediate size at 456 revolutions, and the smallest at 570 revolutions per minute. The generators work at a station pressure of 2,000 volts with a frequency of 78 revolutions. The contractors for the whole of the generating plant were Messrs. Siemens Bros. and Co.

Condenser and Evaporator Casemate.—In one of the casemates, Messrs. W. H. Allen, Son and Co. have erected a surface condensing and feed-make-up evaporator plant, capable of condensing 15,000lb. of steam per hour under a 25-inch vacuum. Water for the condenser circulation is obtained from the sea, the suction and ejection pipes having entailed a considerable amount of difficult work in their erection, they having had to be passed through brickwork 12ft. thick and taken 100 yards out to sea beyond the new breakwater. The surface condensing plant of Messrs. W. H. Allen, Son and Co., as is well known, consists of a horizontal circular shell, containing a number of longitudinal tubes fixed between two plates and providing a large surface for the condensation of the steam. The condenser at Gibraltar has a tube surface of 1,200 sq. ft. Surmounting the condenser shell is one of the feed-make-up evaporators, which consists of a horizontal shell, containing a smaller circular and longitudinal tube shell, the two being arranged very much after the manner of the shell and flue of a Cornish boiler. Live steam is passed through the tubes in the tube shell, and this evaporates water contained between the inner and outer shells, the water thus evaporated passing away to the hot well as a feed-make-up. The feed-make-up evaporators are, of course, only used on occasion, and not continuously. The circulating pump is of the centrifugal type, direct-coupled to a small vertical steam engine, and the air pumps consist of direct-acting steam-driven pumps of Messrs. Allen's "Conqueror" type. In the condenser casemate there are also erected two oil filters, together with a strainer, for the circulating pump sea water suction, this latter being constructed of galvanised sheet iron.

Switchboard Casemate.—The switchboard, which was built by Messrs. Siemens Bros. and Co., is shown in several of the accompanying illustrations. The panels already fitted include four exciter panels, four alternator panels, and four circuit panels, together with a synchronising panel. The spare panels include two spare alternator panels and two spare circuit panels; all the panels being of enamelled slate. Those for the alternators are each equipped with an ammeter, main switch, two fuses and a synchronising switch. The circuit panels are each fitted with an ammeter, a main switch and two fuses. On the synchronising panel there are three Kelvin electrostatic voltmeters, made by Messrs. James White, of Glasgow, a Thomson-Houston station wattmeter and a station ammeter. The switchboard connections are shown in a diagram which accompanies the scale drawing of the switchboard.

Feeders and Distributing Mains.—The whole of the mains throughout the system consist of concentric cables. Both conductors are insulated by bitumenised fibre, and the outer is then lead-sheathed, yarned, armoured by two steel tapes, and finally yarned and compounded. The cables are laid direct in the ground, and wherever possible they have been kept under the footpaths, great care having been exercised in placing them so that they would not be likely to be injured. In the North District, that is in the town of Gibraltar itself, a heavy high-tension ring main is run from the station to supply the various sub-stations; and the outlying sub-stations at the Moorish Castle, at the Water Port Gate and at Hargraves Parade are connected to the ring by smaller high-tension cables. A high-tension concentric cable is run separately from the generating station to the Alameda to supply Rosia and the southern portion of the Rock.

All the consumers are supplied from the various transformer sub-stations by means of a low tension network. In the Northern section—*i.e.*, the town of Gibraltar itself—these low-tension distributors have been laid in almost every street, so that supply can be given to all intending consumers. The network consists of concentric cables of either 0·15 or 0·10 sq. in. section, there being also a small quantity of 0·075 for the less important streets. In South Gibraltar and Rosia the low-tension network is not yet so extensive, but nearly all the Government buildings are already connected.

In addition to the cables for the supply of house lighting, a very extensive system of mains has been laid to supply the street lamps. All the gas lamps will be replaced by incandescent lamps and the cables to supply these are two and three-core vulcanised bitumen cables, armoured either by steel tape or by lock coil segments. Branches are taken from the underground mains to each of the lamps, the supply cables ending in boxes placed immediately underneath the lantern, so as to afford a ready means of disconnecting any lamp, should such be necessary.

The whole of the mains have been manufactured by the Callender Cable and Construction Co. (Limited) and the work of laying has been carried out under their supervision and with the assistance of their jointers. Mr. Alfred Pocklington has been their resident engineer in Gibraltar and has superintended the work on their behalf.

Sub-Stations.—There are five sub-stations at present equipped, two of which are shown in the accompanying illustration. The transformers in these stations were built by the Brush Electrical Engineering Co., and transform from 2,000 volts to 110 volts (2-wire) for the general supply, and 220 volts (3-wire) for the street lighting. The sub-stations controlling

Digitized by Google

the street lighting are provided with switches, as beforementioned, for cutting out half the lamps at midnight.

Street Lighting.—The greater part of the street lighting is by means of Ediswan glow lamps, there being some 500 of these already in operation. These consist of lamps of 8, 16 or 32 c.p., arranged singly or in groups in the lanterns, and carried for the most part in ornamental brackets attached to the walls of buildings. In some few cases these lamps are carried on posts. We may mention that for some years past Ediswan lamps, fittings and accessories have been supplied to Gibraltar.

Conclusion.—In conclusion we have pleasure in acknowledging our indebtedness and tendering our thanks to Mr. A. H. Preece for his assistance in supplying us with some of the particulars and drawings, &c., which have enabled us to prepare this article. Our thanks are also cordially given to Mr. M. S. Chambers, the resident engineer at Gibraltar, for the information with which he supplied us, and the courtesy he showed us upon the occasion of our visit to the electricity supply works at Gibraltar last year. All concerned are to be complimented upon an excellent piece of work.

CONTEMPORARY ELECTRICAL SCIENCE.

[Compiled by E. E. Fournier d'Albe.]

Gold and Platinum Coherers.—E. Branly controverts the assertion which has been gaining ground that gold and platinum are substances unsuitable for use as coherer metals. As a matter of fact, they are highly sensitive, and require some care, but are capable of giving very constant results. Several metals will give very different results in the hands of different observers. To ensure similar conditions, none but sifted filings should be used, and the diameter of the grains and their massing should bear some relation to the E.M.F. of the cell inserted in the coherer circuit. In the author's arrangement the filings are pressed between the ends of two metallic rods, which are made to approach each other by a screw motion. The latter is hardly necessary, as with a little practice the hand is able to impart the necessary pressure. The coherer is enclosed in a cage provided with a slit. Platinum under the same conditions gives equally good results, and shows a high sensitiveness—about the same as silver. The commercial alloys of gold, from those employed for coinage down to the poorest, may be employed with less caution. All these results are in accordance with Lodge's theory, if we suppose that even the nobler metals are not in close contact under ordinary circumstances.

[Branly, *Comptes Rendus*, Dec. 26, 1898.]

Toronto Magnetic Observatory.—When the British Association met at Toronto in 1897, the foreign magneticians present were invited to visit the magnetic observatory, to inspect the magnetic curves there obtained, and to give an opinion on the advisability of removing the observatory to a site less subject to disturbances from the trolley cars. Profs. Rücker, Carey, Foster, Fitzgerald, van Rijckevorsel and Bigelow accepted the invitation, and came to the conclusion that the efficiency of the observatory had been seriously impaired. It was then decided to remove the observatory, and a point was selected nine miles to the north-east, easily accessible by railway, and yet very unlikely to be invaded by the trolley system. At present there is no electric railway within seven miles, and little prospect of one within five miles for many years to come. The name of the place chosen is Agincourt. The new observatory was finished early in September. By October 1st all the instruments had been adjusted in their new positions, and everything was running smoothly. In choosing the building material every stone was tested for magnetic effect. The office is heated by a copper stove. The results have been very satisfactory. All the photographic records will be sent for development to the Toronto Observatory, which continues to be the central office of the Meteorological Service of Canada.

[R. F. Stupart, *Terr. Mag.* December, 1898.]

Search Light Intensities.—According to A. Blondel, the luminous intensity at any point of a surface cutting a projector beam at right angles may be represented by $k\ u\ i$, where i is the intensity of the source, k the coefficient of transmission, and u the "coefficient of optical effect," depending upon the structure of the apparatus. For dioptric apparatus (Fresnel's lenses) the coefficients k and u diminish from the centre to the edge of the apparatus, whereas in reflecting apparatus the luminous intensity is sensibly the same across the whole section of the beam. A Blondel and J. Rey have verified this for a Mangin projector, using an iron screen placed a little in front of the projector, and pierced with a number of equal holes. The images of the carbon arc produced by these holes were caught upon a photometer screen always placed at the same distance from the sheet-iron screen. By boring the holes at regular intervals across the surface, a very exact estimate is obtained of the candle-power of successive zones. In a Mangin parabolic projector, the luminous intensities in zones, differing in diameter by 6cm., were, counting from the axis of the beam, 0, 104, 181, 205, 208, 214, 208, 206, 200, 186 and 185. The initial zero denotes the shadow of the carbon itself. It will be seen that the luminosity is practically constant, except in the central portion. By adding up the zones, the total effect of the beam may be obtained without leaving the laboratory. The Mangin mirror gives 55,719,000 c.p.

[Blondel and Rey, *Comptes Rendus*, Jan. 31, 1898.]

Reaction Pressure of Cathode Rays.—For our views as to the true nature of cathode rays, the reaction pressure which they exert upon the cathode is of vital importance. It is true that they must exert such a pressure, whether they are waves or projected particles, for, according to the electromagnetic theory of light, the pressure per unit surface is equal to the energy per unit volume. But if the cathode rays are projected particles, the analogy fails, unless they have potential as well as kinetic energy. In order to gain some idea of the amount of the reaction pressure, E. Riecke operated with a simple radiometer, the four vanes of which were made to act as cathodes for the discharge from an influence machine. The most important motion observed was the decreasing motion after the current had stopped. It was registered in all its phases until the total stoppage of the vanes. The calculation was somewhat complicated, but the results were fairly consistent. The pressure was found to be proportional to the current strength, and its mean value was 0·04 C.G.S. units. When the pressure is calculated from the heat developed by the impact of the particles upon the glass wall, it comes out as 0·07 C.G.S. units—certainly, a remarkable agreement, considering the difficulties of measurement. So far, then, the results are another confirmation of the emission theory of cathode rays.

[Riecke, *Wied. Ann.*, No. 13, 1898.]

Simple Cathode Rays.—H. Deslandres describes in detail his own results with regard to the dispersion of cathode rays, which he attributes to electrical oscillations of different frequencies, while Goldstein attributes them to differences in the successive values of the potential of the cathode. Neither of them have as yet accepted the emission theory, but Deslandres approaches it very closely when he says that the Hertzian oscillations which are propagated in the direction of the particles act upon them, and that the particles themselves acquire something like a rotation or oscillation—something, in fact, like Newton's "fits." As regards his experiments, they deal chiefly with the electrostatic deflection of a cathode beam by a secondary cathode. When the beam is sifted through a very small aperture it splits up into a number of rays, each with a different amount of deflection. At the same time the individual rays are broadened out at right angles to the direction in which they are deflected, and the widening increases with the amount of the deflection. The best results are obtained when the hole is very small and the screen as large as possible. Since Trowbridge has shown that every spark is really intermittent, it is not difficult to suppose that the three or four successive portions of the discharge have different discharge potentials, and hence that the particles are projected with successively decreasing velocities.

[Deslandres, *Comptes Rendus*, Dec. 26, 1898.]

"ELECTRICIAN" SERIES FORTHCOMING BOOKS.

ELECTROMAGNETIC THEORY, VOL. II.—By Oliver Heaviside. The second volume of this important work is in an advanced stage, and will be ready shortly.

PRACTICAL TELEPHONY.—By Dane Sinclair and F. C. Raphael.

PRIMARY BATTERIES.—A work on this subject will shortly be published, bringing the theory and practice of the Primary Battery up to date. The book will be fully illustrated.

SECONDARY BATTERIES.—By E. J. Wade. Fully illustrated. The Author in this work will deal briefly with the theory and fully with the chemistry, design, construction and manufacture of secondary batteries or accumulators.

"THE ELECTRICIAN" WIREMAN'S POCKET-BOOK.—"The Electrician" Company will shortly publish a valuable pocket-book for the use of those engaged in wiring work, both external and internal.

CARBONS FOR ALL ELECTRICAL PURPOSES.—By Francis Jehl. A work will shortly be published dealing fully with the manufacture of carbons for all electrical purposes. The book will illustrate the machinery and apparatus used in carbon manufacture on the Continent and in America, and will give the latest practice in this important subject.

THE ELECTRIC ARC.—By Mrs. Ayrton. This work will shortly be published, and will contain an historical sketch of the early experiments on the electric arc, as well as the important results of recent research.

SPECIAL NOTICE.

With this issue of "THE ELECTRICIAN" is published a Coloured Sketch Map of London and Provincial Electric Supply Stations, which all purchasers of the Paper should receive gratis. Complaints of non-receipt should be promptly made to THE PUBLISHER.

NOW READY.—Vol. XLI. of "The Electrician," bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

A complete set of the Second Series of "The Electrician" can now be supplied. These sets are very scarce, and early application should be made.

COMPANY PROMOTION "IN BULK."

In several recent issues of The Electrician, but more especially in the editorial columns of the last two numbers, we have directed attention to the more prominent features of the municipalisation of electrical undertakings. We have sought to point out some of the dangers to the profession and to the community at large which appear to be attendant upon municipalisation in the forms in which it has manifested itself; and in doing so we have been actuated by no partisan spirit, but have striven to depict accurately and to deduce justly. The essential principle of municipalisation, viz., the owning and working of commercial undertakings by municipal authorities, may not be, essentially, evil; indeed, it is one of the dangerous features of this latter-day development that in its theoretical or text-book presentment it appears so feasible and as tending so highly to the public good. But, in actual everyday life, the working of commercial undertakings by local authorities—too commonly composed of ignorant and entirely self-interested individuals—has often been attended by many grievous evils, injurious to the interests of the general public and often tyrannising over one or more sections of that public. Between the ideal and the actual, in fact, there would appear to be a wide gulf, the bridging-over of which is a task that gives no sign of being accomplished. In fairness alike to ourselves and to certain local authorities, however, we may say that to the general rule there are some few exceptions—to be found mostly in the larger cities, where the local authorities comprise men able and willing to take a statesman-like and broad view of their responsibilities, and to adopt an equitable and business-like policy therein. In the fortunate localities controlled by such men, municipal undertakings, *e.g.*, for electric supply or tramways, have flourished; and were it

Digitized by Google

not that their success furnishes a pretext for universal municipalisation, we should have nothing to complain of in regard to them.

There is, however, another aspect of the conflict between local authorities and electrical companies besides the one we have depicted; and this now calls for consideration. If the welfare of the community has been menaced in some respects by the selfish attitude adopted by local authorities towards genuine schemes projected by certain companies, there is, on the other hand, no small danger that the investing public may suffer from the depredations of bogus companies asking for enormous sums of money in the promotion of schemes that, even if not inherently preposterous, have but small prospect of yielding any substantial return for the investment. Electrical industry has already passed through one boom, with its consequent reactionary series of financial crises; and, though it has at length emerged from that period of depression, and is now a well-established and important section of the industrial world, this happy consummation would have been attained all the earlier had there been no such artificial inflation as the boom to which we have alluded. A second boom like unto the first would be attended by far more serious and lasting results, for the reason that at the present time the amount of capital invested in British electrical undertakings is enormously greater than in the pioneer days when the industry was convulsed by the reaction from the first boom. The latest development in the engineering aspect of electricity supply is the system of distributing energy over a very large area, and supplying it "in bulk," as the phrase for wholesale supply has become. There are some few localities where the industrial and other conditions so favour such a system of distribution that, at the present time, it might be adopted with financial success by any well-organised undertaking. In these localities a wholesale and widespread supply of electric power might do much to foster industry and trade, and it is greatly to be hoped that the powers that be will encourage such enterprise.

But, although the definite project to supply power in this manner—speaking apart from mere paper schemes—is scarcely a year old, there are already not wanting indications that the "in bulk" principle of electric supply is to be made the basis of a corresponding "in bulk" scale of company promotion and financing. We warn the investing public that the advantages of "in bulk" supply, as contrasted with ordinary urban supply, do not warrant the conclusion that it may be adopted with financial success for any combination of adjacent counties that may suggest itself to the fertile imagination of a company promoter. Nor does it at all follow as a matter of course that a group of electrical nobodies, with probably little money to lose, and perhaps less technical or business reputation, will lead such an enterprise to a successful issue. Financial standing as well as electric technical knowledge is essential. Apparently the method most favoured in the office of the promoter we have in mind is, to select on the map a spot in a coal district—it does not seem to matter much where. That is for the power station. Then a big circle is drawn, embracing several counties, and including a good many towns that already possess electricity works and several more that do not require electricity "in bulk"; and a scheme is drawn up for supply over this area. It does not seem to be considered necessary even that the "scheme" should be backed by men of large financial resource. Statistics are got up to show what a rich field this is, and the public is to be asked for several millions sterling for the privilege of sharing the harvest. Again we repeat, there are but few—very few—areas in the United Kingdom, where, in the present stages of electrical generation and supply, such a scheme could have any reasonable chance of success. Even for these a big battle against the opposing local authorities will certainly have to be fought; and, although it would seem probable that Parliament will admit the principle of "in bulk" supply as recommended last year by the Select Committee, and will legislate accordingly, large sums of money and much time will yet have to be expended in legal expenses before even the most commendable of these schemes can receive statutory sanction. Without doubt, when ultimately carried through, the schemes that are based on genuine economic prospects will offer to the investor a good investment for his money, and it is not of these that we would speak in warning tones. Our object is to put the investor on his guard against unscrupulous and irresponsible company promotion "in bulk," where the "bulk" of the capital invited is out of all proportion to the insignificant financial prospects. The electrical industry has much to fear from "wild-cat" company promotion.

CARBONS FOR ELECTRIC LIGHTING AND OTHER PURPOSES.*

BY FRANCIS JEHL.

(Continued from page 380.)

Should the articles that are placed in the furnace contain a great deal of moisture, as is the case with stoneware, &c., an extra passage is built in the furnace as shown at *l*, from which small branch passages run into each chamber at the top of the furnace, as in the sectional drawings (Figs. 37 and 38). As each branch is governed by a sort of valve, any two chambers can be connected by this means. The object of this extra passage and its branches is, that when a chamber is filled with such damp articles, a portion of the hot air, that is circulating through the chambers that are cooling down, is led on into this passage and from there into the above-mentioned chamber, so that a temperature of about 70°C. to 100°C. is obtained which thus drives off the moisture that is forced to pass into the smoke flue by raising the valve *h* of that chamber slightly. If this was not done the moisture would always condense in the cooler chambers. However, for carbonising electric light carbons, &c., which contain no moisture, such passages are not needed.

It is evident that when working with such a system of furnaces, it is impossible for a negligent attendant to overheat or suddenly expose fresh carbons to a large heat, as can be done when using a periodical furnace, where the flames, or rather the gas, must first be so regulated that very little heat is produced, or else the carbons will warp (as has already been explained in the chapter on carbons). The fact that the hot combustion gases must first pass through several chambers through which the intensity of the heat is gradually toned down as it reaches the last chamber, insures perfect immunity against risks. The operation of the furnace is very simple, while at the same time it is adapted to be used in many industries by simply making some minor changes, as in the number of the chambers, or in different modes of directing the flames, &c.

Articles, such as carbons, that are very sensitive to sudden changes in the temperature, either increase or decrease, require, of course, a furnace having more chambers than an article not so sensitive, or where warping or cracking is of no account as is the case when calcinating. A furnace for carbonising electric light carbons, electrodes, &c., should have from 12 to 14 chambers, or a double furnace from 24 to 28. The cubical capacity of each chamber depends upon the quantity of carbons that it is desired to carbonise, and Mendheim makes them from 4½ cubic metres upwards. Then, again, the flames, instead of issuing upwards from the floor of

Digitized by Google

the furnace towards the ceiling, are generally forced to act in the reverse direction, that is, from the ceiling downwards towards the floor, as far better results have been obtained by this method when baking carbons. Such a modified chamber system is shown in part in Figs. 39 and 40, where *k* represents the mouths or openings from which the gases and air flow out, and, being well mixed, there is almost perfect combustion as the gases are ignited. The flames shoot upwards and then down towards the floor of the oven, and out at the numerous openings *e*, as seen in Fig. 39, the arrows in Fig. 40 indicating the path of the flames.

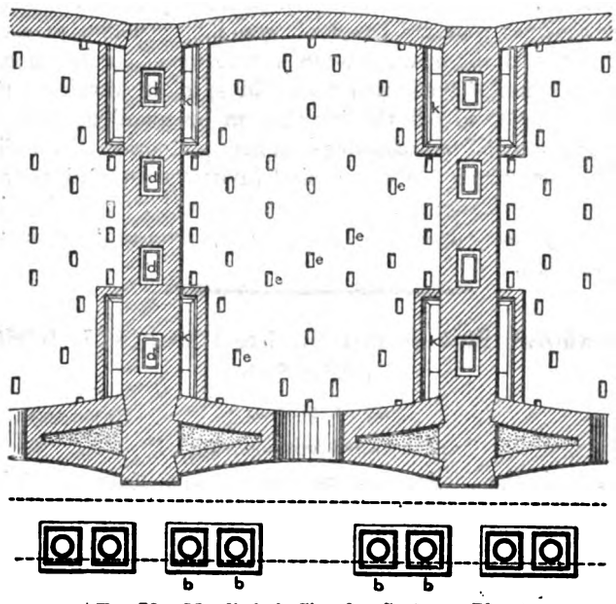

FIG. 39.—Mendheim's Chamber System. Plan.

Each of these four outlets *k* is controlled by valves *b b b b*, by means of which the flow of gas can be regulated.

The gas is led to the outlets by way of the passages *a*, while the heated air that is necessary for combustion passes and circulates through the chambers that have already been finished and thus arrives very hot in the chamber where the combustion is going on, in a similar but reverse direction to that already explained in reference to Figs. 36-38. The heated air has to traverse chamber to chamber by way of the valves *d*, by means of which the chamber can be cut off and the smoke or combustion gases made to pass into the flue *f*

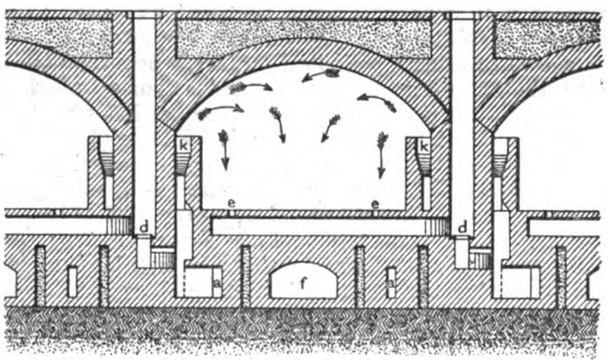

FIG. 40.—Mendheim's Chamber System. Cross Section.

leading to the chimney. The valves in connection with the flue are not shown in the drawings, but it may be stated that the principle of the furnace, its working, &c., is the same as that illustrated in Figs. 36—38, there being only some differences in minor details, such as in the disposition of the air and gas passages, and the direction or path of the flames. From what has been just explained, it will be seen that when retorts containing carbons are placed in such a furnace the whole are enveloped in flames and get evenly heated, as the fire descending from the top divides, and a portion is drawn into each of the openings *e*. Instead of four outlets *k*, as shown in Fig. 39, two long ones can also be made, extending from the front of the furnace to the back on each side of the chambers. The gas and air is generally led into these outlets in a divided way, so that there are a large number of orifices, each alternate one either for gas or air by means of which the gas and air get well mixed, this being so necessary in order to perfect combustion.

It will be noticed what an advantage a carbon factory has that is situated in the natural gas regions of the United States, where such a rich and constant supply of gas can always be obtained. It is then possible to effect a better and more individual regulation of each orifice, and at the same time smaller passages or pipes can be used, as the gas is far more pure, containing as it does far less inert gases than that generated in a generator. Neither is there any danger of condensation of tarry liquids as happens in passages where the gas is generated from fuel containing volatile matter. In fact, the writer believes that the time is very near at hand when the United States will not only make all the high-grade carbons they need, but will be able to supply other foreign markets.

It may be mentioned that there is a saving of fuel of over 30 per cent. when using the Mendheim chamber system of furnace, as compared with that used in a periodical furnace, while in some circumstances, with a negligent workman, the economy may be as high as 60 to 70 per cent. For very small factories, or such concerns that wish to make their own electrodes (of small size), Mendheim builds chamber furnaces, with only two outlets, instead of four, and a slightly different disposition of the passages. Should a furnace with 12 or 14 chambers be too large for such a factory six or eight need only be built, but it is then evident that the work cannot be continuous. With such few chambers the work will be intermittent, but when business increases more chambers can be added, so that the working can be continuous. Nevertheless, even with only a few chambers such a furnace has still a decided economy over a periodical furnace, as some of the waste heat of the combustion gases can still be used, although not in such a perfect sense as when working continuously.

There are some carbon manufacturers who employ the gas ring system of furnace, which, like the chamber system, can also be worked continuously while at the same time there is a similar economy of fuel. Although those conditions and requirements that are necessary for carbonising carbons are also attained in a limited sense in this kind of furnace, it may be mentioned that, on the whole, the chamber system is to be preferred. In fact, one of the best carbon makers of Europe, who worked with the gas ring furnace, built a Mendheim chamber furnace when he erected a branch factory in France. In principle the gas ring furnace is simply a large endless passage in which a shifting fire is always in operation at one part or the other. This passage or ring is generally divided in a number of parts, each part being alternately heated as in the chamber system. The air that is necessary for the combustion does not flow, however, like that in the chamber system, from the bottom or top of a part, or parallel to the gas; on the contrary, it meets the gas at right angles. The air supply simply circulates directly through (in a straight line) those parts which contain the finished carbons, and thus meets the combustible gases that issue either from the floor or sides of the part that is getting heated. The products of combustion continue in the same path until they are forced to enter the chimney flue at some distant part of the ring.

ELECTRICITY WORKS ACCOUNTS.

Leicester Municipal Electric Supply Works.

The electricity works accounts, which form the subject of our analyses this week, are those of the working during 1896 and 1897 of the Leicester municipal undertaking, which commenced supply December 19, 1894. At December 31, 1897, the total authorised capital stood at £76,467, out of which £42,748 in total had been borrowed, viz., £37,748 on Three per Cent. Redeemable Stock, £4,700 on Three per Cent. Debentures and £300 on Two and Three-quarter per Cent. Debentures. The capital expenditure had, at the same date, amounted to £45,853, representing the low rate of £68 per kilowatt of generating plant in the station.

A comparison of the data in our table for the two years referred to reveals the fact that good progress has been made not only as regards the extent of business done, but also in the matter of economy of working. As compared with 220 consumers, representing an equivalent of 16,864 8 c.p. lamps connected at the end of 1896, we find that at the end of 1897 there were 331 consumers and the equivalent of 23,757 8 c.p. lamps connected to the mains. Corresponding to an output in 1896 of 169,668 units sold, there were 262,179 units sold in 1897, being an increase of 54·5 per cent.

The average total revenue obtained per unit was 5·53d., of which about 4·99d. was for electricity supply and 0·394d. represented the profit on sale of lamps and fittings. As compared with the previous year, the total costs for 1897 show a decrease of 0·78d. per unit; these at 3d., works costs at 2·34d. and generating costs at 2·05d. were still above the average for stations of similar output; however, the substantial reductions effected in these items are we hope but earnest of further economies in the working during 1898 and future years.

A working profit of £2,758 was made, representing 6·57 per cent. of the mean expended capital of the year. Out of this gross profit £1,164 was carried to the sinking fund which amounted to £3,741, and £1,360 was paid as interest on loans. The balance, or net profit for the year, of £234 served to reduce the deficit of previous years' working from £1,603 to £1,370.

The following data respecting the working during 1895 is of interest as a further index of the progress made. At December 31, 1895, the capital expended was £33,080, the number of consumers was 133, and the equivalent 8 c.p. lamp connection 10,184. The output for the year (1895) was 77,797 units sold, the total revenue £2,537, while the corresponding total costs were £1,857.

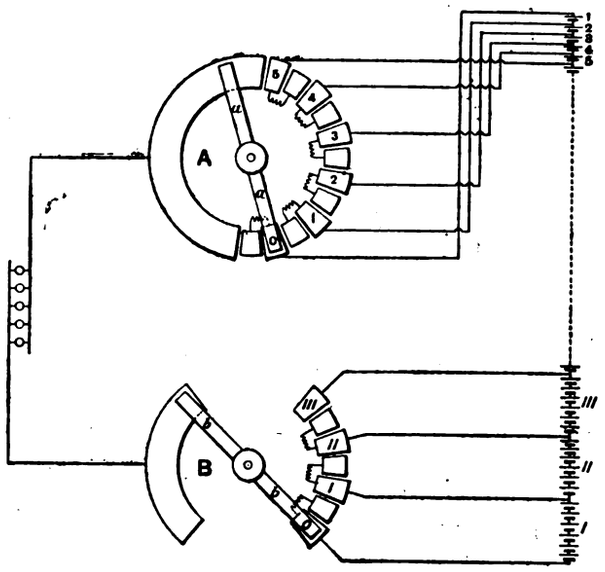
A NEW ACCUMULATOR SWITCH.

A useful form of accumulator regulating switch, designed to lessen the number of connections between the battery and the switchboard, is being manufactured at an electrical apparatus factory at Aarburg, Switzerland. The principle of the switch, which is due to Messrs. Erlacher and Besso, is shown in the accompanying diagram; in the actual switch, however, the two dials are arranged one above the other, and the handles are interlocking. The diagram supposes 23 regulating cells, but instead of 25 cables being required from the battery to the switchboard, 10 only are required. There are five cells whose terminals are brought to the switch, the other 18 cells being arranged in groups of six. If, as an example, 10 cells are to be cut out, the switch arm *b* of the dial B would be placed on the contact I, cutting out six cells, and the arm *a* of the dial A would be turned to the contact 4. The interlocking arrangement is such that the arm *b* is only moved when the arm *a* passes the

Digitized by Google

position 5. Thus if at the beginning all the battery is in circuit, by turning the handle *a* the first five cells are successively switched out. The next step of the handle, however, simultaneously switches out the six cells of group I. and restores the first five cells to the circuit, the handle *a* having made half a revolution. In this way, merely by turning the handle which controls both dials, any number of cells from 0 to 23 can be switched out or in again. Resistances are interposed in the usual manner between the cell contacts to obviate short-circuit or total disconnection.

Not only is there a considerable saving in cost by diminishing the number of conductors required, but it is stated, that owing to the diminished number of contacts and connecting thimbles, the



switch itself is cheaper than one of the more common type dealing with the same number of cells. We understand that the makers also supply a switch actuated by a motor through worm gearing, and arranged, if necessary, to act quite automatically.

INDUCTION TELEGRAPHY.

The following is an abstract of the discussion which took place at the Institution of Electrical Engineers, in connection with the Papers on induction telegraphy read by Dr. Oliver J. Lodge, Mr. Sydney Evershed and Mr. W. H. Preece (speakers who have returned their proofs revised being indicated by an asterisk:—

December 8, 1898.

*Mr. W. H. PREECE said that it was the first time he had listened to anybody else holding forth on this subject of wireless telegraphy. It was now exactly 16 years since he first brought the subject before the British Association, and year after year, from 1882 to the present time, he had never failed to report to the British Association the experiments that he had made. Prof. Lodge had that evening explained his views and described his plans for earthing so ably that he (Mr. Preece) felt that the time had arrived when something should be done to test this mode of calling on a practical scale. The next day he was going to have the pleasure of an interview with Prof. Lodge, and he hoped they would come to some decision to give this system a practical trial.

December 22, 1898.

*Mr. SYDNEY EVERSHED said that if induction telegraphy ever came into practical use it would not be to replace or to displace wire telegraphy. It would be for use where a wire or cable could not possibly be laid, and, therefore, it amounted to a matter of cost, and his Paper was rather prepared from that point of view. In order to arrive at the cost they must consider three items—(1) the arrangement of the circuits, (2) the arrangement of the transmitting device and the manner they were to obtain the power and the amount, and (3) the receiving devices—the most important of all. The most important thing to know about this third item was what power did it take to work them, because there was only a very limited amount of power which could possibly be received in a secondary circuit at a distance, and that amount must suffice for working an indicator. He was very glad to see that Dr. Lodge supported the arrangement which, from the very first, he had advocated, viz., that the circuits should be laid in the plane of the earth with their magnetic axes vertical. The very first induction telegraph that he had worked out was in 1892 effecting communication with a light vessel. His idea had been to communicate with all the light vessels round the Kentish coast by laying a circuit completely round the county of Kent. He found, as would naturally be expected, that the cost was absolutely prohibitive unless they had the means of employing an immense amount of power. He then devised a means for communicating with the North Sand Head light vessel, referred to in his Paper. Dr. Lodge had stated that the sea would not have much absorbing influence, but it did have a very considerable influence; even with so low a frequency as 16, the sea caused an absorption of nearly 40 per cent. But even had the sea been absent, the iron of the ship would have been a fatal bar. The total absorption amounted to 97 per cent., and he considered the experiment absolutely conclusive. When they came to telegraphy on land the matter was rather different, because, so far as they knew, the earth was a very poor conductor. If its specific resistance was high enough, telegraphy could without doubt be carried on by means of magnetic induction. He noticed that Dr. Lodge had hesitated whether to take the electromotive force or the current in designing the circuits. Price would depend very much upon the power. Turning to the transmitting devices he said they could use interrupters. They gave trouble from sparking, but this could be got over to some extent by using a condenser. Another arrangement was the one which Dr. Lodge had described, viz., an alternator, and a condenser in order to bring the current into step with the electromotive force, and get the power factor up to unity if possible. However, it was his opinion that if the difficulty of a suitable indicator could be overcome, there was little difficulty in providing a proper transmitting appaaatus. Now he came to the receivers, and as these had to detect alternate currents, it was probable that in every case they would be vibratory instruments. Although at present, in the case of a telephone, they were unable to measure the amplitude and the power, they could measure the minimum ampere turns on the coils necessary to produce an audible note. Mr. Cox and himself had measured this at Woodfield works some years ago, together with Mr. Gavey and Mr. Kempe, of the Post Office, and they all agreed with each other. No doubt the human ear varied from time to time, but under the same conditions four average men had heard just about the same faint note. He had compared his result with that of Lord Rayleigh for a similar type of telephone. Lord Rayleigh had said that 1·6 milliampere turns of alternate current in the telephone made a clearly audible sound (0·8 milliampere turns just audible). Mr. Gavey, Mr. Kempe, Mr. Cox and himself had been able to hear 1·4 milliampere turns, distinctly enough for signalling, and they could hear quite distinctly with half that amount, so that they did not differ very greatly from Lord Rayleigh. However, he would not go into the theory of the telephone, because he thought there would be great trouble in working at anything like a frequency of 400 over great distances, in consequence of the absorption. He had been working at a system operating at something below 50 periods, and the only relay he had been able to devise up to the present was one for calling attention. At present it only rang a bell for calling attention, but something on these lines would ultimately be brought out for giving Morse signals. The complete theory of this relay and a statement of the power it required were given in the Paper. This instrument had been designed to work on board a light vessel—a very difficult position. He had made the rectangles on the twin system in order that any ordinary shaking should not produce an accidental close of the circuit. If a blow was given to the relay, the rectangles were started in the same phase and did not come into contact; but the moment an electrical disturbance came into the coils they were vibrated in opposite phases and came into contact. This proved to be a very valuable feature. As Dr. Lodge had mentioned in his Paper, this relay was in use satisfactorily at Lavernock and Flat Holm. Dr. Lodge had stated, however, that the result had been obtained at the expense of a good deal of power. So far as he could make out, Dr. Lodge himself was now using from 500 to 900 watts in the primary in connection with his transmission between the Liverpool College and his house, whereas they only used 120 watts in his (Mr. Evershed's) call. Possibly Dr. Lodge was judging from the size of the alternators at Lavernock and Flat Holm, but, as a matter of fact, these were far too large for the job. The current there was only 8 amperes, and the resistance less than 2 ohms. The rectangles in his relay would work with but $\frac{1}{1000}$th of an erg per second against 42 ergs for a tuning fork. Many questions had been raised as to whether Mr. Preece's system was due to induction or to leakage. Why did not the people who raised the question measure the leakage? In the spring of this year Mr. Gavey and himself, among other things, measured the leakage at Lavernock, which, to their astonishment, was very great, with continuous currents, but with alternate currents the leakage fell off rapidly as the frequency increased. Referring to Dr. Lodge's experiments at the previous meeting he asked him how much current, or how many ergs per second it took to get audible sounds from the last telephone of the series in his experiment. In conclusion, he stated that throughout, the whole of his work on this subject, he had been assisted in every possible way by the Post Office, and he could practically have done nothing without this help; with it he hoped to be able to do something to clear up definitely this question of absorption.

*Mr. W. H. PREECE informed the meeting that the work the Post Office had done during the past 16 years, and which he had summarised in his Paper, had been purely and absolutely experimental. He showed to the meeting a similar apparatus to the one working between Lavernock and Flat Holm, and operated it successfully.

*Dr. FLEMING considered that the time had hardly arrived for a complete classification of methods of space telegraphy, but, leaving out of account certain methods such as Zickler's, perhaps in an embryonic condition; and, omitting the cases of mere conduction through soil or water which were not space telegraphy at all, it was clear they were in possession of two distinct practical methods which he ventured to denominate the closed circuit and open-circuit systems respectively. The method devised by Mr. Preece and elaborated by Dr. Lodge virtually consisted in the construction of a gigantic air core alternating-current transformer, the coils of which might be several miles apart. Dr. Lodge then very ingeniously took advantage of the resonance effect, well known in connection with alternating-current transformers when worked on long concentric cables, to exalt the secondary electromotive force. The open circuit

Digitized by Google

system, brought into notice chiefly by the interesting experiments of Signor Marconi, consisted in the creation of alternating currents of very high frequency in a straight (generally vertical) rod or wire. The disturbance sent off in the form of an electromagnetic wave created at distant places along a certain line a periodic electric force parallel to the primary conductor and a magnetic force at right angles, and the effect in a parallel open secondary circuit placed in the proper position was detected by a Branly detector inserted in it. One terminal of the induction coil and of the coherer or receiver was earthed. Dr. Lodge had suggested that the action of the receiver depended, at least in part, on "electric jerks" received through the earth. Dr. Fleming remarked that he had been led by some little study of the Branly detector to the conclusion that it responded to a certain maximum electromotive force, the metallic filings passing from a condition of nearly perfect non-conductibility to a high degree of conductibility, when the mass was submitted to a certain critical or breaking down electromotive force. Hence, when the coherer was in connection with a long metallic rod, placed in a space through which electric waves were travelling, so that the rod was parallel to the electric force arriving there, the rod integrated the electric force along its length into electromotive force. Accordingly, if the electric force was feeble, but the rod very long, the critical electromotive force might yet be reached. In the closed coil system of space telegraphy it was necessary for the secondary coil axis to be parallel to the magnetic force at its locality. In the open circuit system it was necessary for the secondary or receiving rod to be parallel to the electric force. Dr. Fleming illustrated the above fact by an experiment. From one corner of the hall electric waves were sent out in the customary manner by an induction coil and spark balls. On the table he had a Branly detector connected with a relay, battery and electric bell, in the usual way. The coherer was inserted in the gap between two long receiving rods placed in one line. When the rods were held parallel to the electric force produced at the receiving station, the bell rang out loudly; when the rods were held at right angles to it, the bell nearly ceased to ring. Dr. Fleming then described an experiment he had recently made in Regent's Park, on the absorptive power of water for electromagnetic disturbances. A long copper wire, one-eighth of a mile long, was laid down in the lake, and one end of it was attached to the spark-ball terminal of an 8in. induction coil. The other end was attached to one terminal of the coherer in the above-mentioned bell apparatus. Under these circumstances no electromagnetic impulses could be caused to travel along the wire, although when the wire was lifted out on to the dry ground the waves travelled along it freely, and caused the electric bell to ring. This experiment indicated the impracticability of the suggestion to employ the coherer or Branly detector as a relay for submarine telegraphy through bare wires, a suggestion which had already even found its way into patent specifications. Dr. Fleming added an expression of opinion that in none of the practical Hertz wave telegraphy as yet carried out is there any true electric resonance effect. Before that could be achieved it would be necessary to possess a transmitter which would not merely create irregular or intermittent impulses in the ether, but would establish continuous uniform wave disturbance of high amplitude and small wave-length.

Major-General WEBBER called attention to the following words spoken by Mr. Willoughby Smith on the 23rd March, 1882, in the discussion on Prof. Dolbear's Paper, "On the Development of a New Telephone System":—"I was prepared to have shown that by placing a flat spiral of fine silk-covered wire in the centre of this room, the spiral being connected to a suitable transmitter and battery, that every person present possessing a telephone would have been able to have heard whatever sound was influencing the transmitter, although the telephones were in no way attached to the circuit." He believed this remark had induced many, including himself, to investigate this very interesting subject.

*Mr. C. S. WHITEHEAD said that Dr. Lodge had raised the question as to whether certain of his equations applied when the frequency was as low as 300. As a matter of fact, his equations were, with a certain assumption, directly derived from Maxwell's equations; hence, Dr. Lodge's objection must refer either to the assumption or to Maxwell's equations. His assumption was that the polarisation current could be neglected, since the frequency was only 300, and not comparable with that of light. This, he contended, was justifiable. As to whether Maxwell's equations applied, he referred Dr. Lodge to the books of Prof. J. J. Thomson, Dr. Hertz and Oliver Heaviside, in which, as well as in many other electrical Papers, they all started by using Maxwell's equations. If Maxwell's equations were not true, where were the ones which should be used instead?

*Sir HENRY MANCE suggested to those who were working on this subject, that instead of simply breaking and making the vibration in order to get signals, they should alter the note of the vibration, a method which he thought would enable them to get a far greater sensibility. As a case in point, some thirty years ago he had to deal with a line in which the working broke down regularly every night until they introduced fluid insulators. One of the instruments had the make and break mechanism of an old bell in circuit, and there was a slight hum, from which he could, by the alterations in the note, distinctly read the signals transmitted from the other end of the line, 400 miles distant, although no current whatever could be observed on the galvanometer.

*Mr. A. R. SENNETT was disappointed to hear Mr. Evershed throw a considerable damper upon the question of the connection of lightships and the mainland by wireless telegraphy simply on the score of expense. The English people were proud of their maritime supremacy, and he did not think they ought to be daunted by either electrical or financial difficulties. Mr. Wimshurst had suggested to him that what might be called an induction swivel should be inserted in the cable connecting a lightship and the shore. The Trinity House authorities ought to try such a simple thing. He had made experiments in transmitting vibration through the water, and was strongly of the opinion that no electrical current or influence was necessary. If they transmitted sounds through the water by means of an electrically-driven siren, it was simply surprising how many miles they could hear it. Experiments had been made last century the whole length of Lake Geneva (48 miles), and it seemed to him that all they had to do was to devise a sensitive receiving instrument and tune it with the note they were transmitting through the water. He had made such an instrument, and found it very sensitive. He had first of all taken a membranous diaphragm and put it in the mouth of a Helmholtz resonator, and to the diaphragm had connected a microphone. The secondary of the induction coil went to a telephone magnet, and this was mounted in front of a similar diaphragm and resonator to the first. He had found it advisable to put the first diaphragm at an angle of 60deg. This first diaphragm was not fitted as in an ordinary telephone, but could be tuned as the skin of a kettle-drum. A Helmholtz resonator, as they were aware, was provided with a slider and by pushing this slider in and out they could get this diaphragm tuned to the greatest possible sensibility. He contended that if they were to put an arrangement of this kind on a lightship, and transmit from the nearest harbour, say 20 or 30 miles away, the vibrations from a bell or siren, the sound would be heard quite distinctly. Dr. Lodge had demonstrated the characteristic sound which they all recognised in a telephone, and which was very troublesome. To find a way of getting over it it was only necessary to consider the construction of the human ear. First of all, in the human ear an oval diaphragm was made use of. Secondly, there was glued, as it were, to the back of that diaphragm a bone at a certain angle. This prevented the diaphragm from having more than two radii of the same length, and the consequence was that it practically had no fundamental note. If the ear could speak instead of listen, it would naturally have no intrinsic *Klangfarbe* or note of its own; therefore, if Dr. Lodge put the magnet of his last telephone in the same position as the bone in the ear and constructed a diaphragm after the manner of the human ear, he would considerably diminish the characteristic or nose sound.

*Prof. W. E. AYRTON thought it possible that the members present may not have appreciated the importance of the investigation to which Mr. Whitehead had referred. Some three years ago, when Mr. Evershed had made such an extremely sensitive call as the one he had exhibited that evening, he did not know what sized piece of copper to put between the primary and secondary coils to represent the sea in his experiments. He (Prof. Ayrton) had entered into a correspondence with Mr. Oliver Heaviside on the subject, who was of the opinion that the absorption of the sea would not be a sufficient justification for Mr. Evershed not to try his system practically. Mr. Whitehead, who was then a pupil of Prof. Ayrton's, had, at his instigation, taken up the matter mathematically, and had shown his results to Prof. Ayrton before bringing them before the Physical Society. He (the speaker) was, therefore, to an extent, responsible for the basis of the calculations. Now, if that calculation was wrong in principle, he would be extremely obliged if Dr. Lodge would point out why it was wrong. If Maxwell's equations did not hold good he should like to know what equations did. So far as he remembered, the discussion on Mr. Whitehead's Paper, as reported in the *Proceedings* of the Physical Society, consisted chiefly in a long communication from Mr. Oliver Heaviside, in which the only point he objected to was the conductivity of sea water. But, thanks to Mr. Heaviside's kindness and interest in the subject, another method of attacking the problem was suggested, which, however, he (Prof. Ayrton) need not enter into then. Therefore, up to the time that Dr. Lodge had read his interesting Paper a fortnight ago, he (Prof. Ayrton) had been under the impression that the equations were correct. It was important to know whether, in 20 metres of sea water, there was an absorption of something like 79 per cent. If that were a fact, it seemed almost hopeless to continue the method which Mr. Evershed had tried for calling attention by acting inductively through such thicknesses of sea water. If, on the other hand, the fundamental equations were wrong, he had no doubt that Mr. Whitehead would attack the problem again and see what he could get. Since the last meeting Mr. Whitehead had brought him another investigation which he had made on the absorption between coil and coil laid flat on the land. This had been based on the same equations of Maxwell, and until they were sure about the accuracy or inaccuracy of these equations he would not suggest that Mr. Whitehead should publish the results of this new investigation. He gathered from Mr. Evershed's Paper that it only took $\frac{1}{10^{60}}$th of an erg per second to work one of his relays, so that 10,000 million of his relays could be worked with one watt. Would Dr. Lodge tell them what power had to be given to the first telephone of his train of telephones—was it more or less than this?

*Dr. OLIVER LODGE (replying to the discussion as far as it had gone that evening) said that he had been unaware of what Mr. Evershed had been doing, but he was very glad that he had now published it. He never intended to suggest that space telegraphy would displace wire telegraphy as Mr. Evershed had seemed to think. He had always said that whenever they could lay a wire it was better to do so. There were cases, perhaps, such as newspaper intelligence when they wanted to shout it all over the country, but even then he did not think Mr. Preece would like them to do it by induction telegraphy, because it would disturb the telephones. But perhaps Mr. Preece did not care whether they were disturbed or not. So far as he had had it working at Liverpool, his call had taken more power at the sending end than Mr. Evershed's, but nothing like that amount was necessary with a long base-wire or with the receiving apparatus he had shown. From the results of his experiments in his laboratory he felt convinced that the power that was used for getting an audible sound—which was quite a small power—would be quite sufficient to work the call with his magnifying arrangement. He could not answer the question at once as to how many ergs were required to work the first telephone, but could only say that it was much less than was required to work an ordinary telephone. He would endeavour to supply the figure at the next meeting. The speed of signalling by a tuning fork might have been expected to be rather slow; but using a

Digitized by Google

frequency of 300 or 400 per second, as fast as an operator worked the key, the telephone responded. He had slightly modified his tuning fork arrangement by making the upper prong of the fork carry the screw and the lower prong carry the carbon. Therefore, when the fork vibrated properly, the microphone was put into action; but any small jarring of the fork, as a whole, did not affect the apparatus. He did not wholly agree with Prof. Fleming's remarks as to the uselessness of an earthed wire. He had made some experiments with an earthed wire or gas pipe by sending an electrical "jerk" or rapid rise of potential through it, and had been surprised at the immense distance at which a coherer could feel the effect of this current. If the wire was very clean, no doubt it did not go so far; but what they meant by bare wire was a roughly and imperfectly insulated one, and with such a wire he believed, by the method of "jerks" on the coherer, a good deal more could be done than Dr. Fleming's remarks would lead them to believe. It was not necessary to put the coil at the bottom of the sea, in signalling to lightships electromagnetically. It should be kept in the dry, and the absorption of the sea water would then have less effect. He was anxious to remove the misapprehension into which Mr. Whitehead seemed to have fallen. He had not meant to convey that Mr. Whitehead was wrong, but that these were discrepancies between the calculations of different mathematicians. His feeling was that the theory as given by Maxwell could not apply to all frequencies. In the problem of the transmission of light through a partial conductor, the absorption of energy comes out independent of the frequency, yet they knew experimentally that conductors were not equally opaque to waves of every length. Then there was another problem, as to the effect of the earth near but not between a pair of induction circuits; this was a matter for mathematicians, and last week he had written to Prof. J. J. Thomson suggesting this problem to him. Just as he came to the meeting that evening he had had a letter from Prof. Thomson saying that he had got a solution, but that he had not yet reduced it to arithmetic.

January 12, 1899.

Mr. SYDNEY EVERSHED corrected his statement made in his Paper that he had been appalled by the large size of the condenser necessary, consequent on the large self-induction of the circuit, in connection with his scheme for laying a circuit round the county of Kent, in order to effect communication with the lightships round the coast by means of an induction telegraph. He intended to say that, in consequence of the low frequency at which his apparatus was intended to work, the size of the condenser was necessarily large. Of course, the larger the self-induction the smaller the capacity of the condenser. The reason that the circuit required such a large condenser was that he proposed to work at a frequency of 12 periods per second.

*Dr. O. J. LODGE asked Mr. Evershed to correct another statement of his, viz., that his relay at Lavernock took less power than was required for the telephone. In other words, that a telephone, working at 400 periods per second, had 600 times the power applied to it it would get at 16 periods, meaning that the power varied as the square of the frequency, but this was ignoring the self-induction of the line altogether. The pL term was 10 times as great as the resistance term in the Lavernock line wire at 400 frequency. Working at 16 periods per second, on the other hand, r could stand alone as the denominator. He had been asked last time as to the power necessary to work his magnifying telephone—the first of the series. He had had a determination made, and had found that the current required was about a micro-ampere in a circuit of an ohm resistance; one millionth of a millionth of a watt was sufficient to give an audible signal. The magnifying telephone was in fact about 30 times as sensitive as an ordinary telephone, and that was without taking any precautions whatever; probably with care it could be made more so. But in Mr. Evershed's relay there was a visible motion of the rectangle, the wire actually moved in a magnetic field, and, therefore, they got a back electromotive force. In his system it was merely necessary to vary the pressure on the carbon—there was probably no back electromotive force to speak of. All that the signalling current had to do was, as it were, to pull a trigger, thereby throwing fresh energy into the circuit from the local batteries, and the resulting energy from the final telephone bore no necessary relation to the current in the circuit that pulled the trigger. As to the opacity of sea-water, he had got to the bottom of this and realised a sort of reconciliation between Clerk Maxwell's calculations and those of Mr. Whitehead. It turned out that both were right, but that both referred to different cases. They were both extremes, and if either was wrong in its application it appeared to be Maxwell. Maxwell dealt with gold leaf, and got a transparency less than experiment gave. But Mr. Heaviside had, in 1887, published a more general theory which included both these extremes, and this had reconciled the whole thing. He proposed to say something about that at a meeting of the Physical Society on Feb. 10th. He would ask Mr. Evershed if in his experiments on the Goodwin Sands the ship was of iron, if the cable was inside the ship, and if the primary cable at the bottom of the sea was sheathed in iron. If these things were so, no further explanation was needed as to the failure of the experiment. He made some experiments himself about six months ago on the effect of neighbouring conductors near the primary coil. A sheet of copper produced a great effect, as they might expect; a sheet of tin foil produced very little, and a pan of dilute acid produced no appreciable effect, hence he had thought it likely that liquid conductors need not very much be taken into account. Prof. J. J. Thomson's solution of the effect of the earth, which he mentioned last time, was very complicated, but it appeared from it that the earth might almost as well be taken as a perfect conductor, in which case it would not do to work with horizontal coils. Looking at the subject from an elementary point of view the horizontal coil above the earth's surface induced an image below the earth's surface, the current through which would be in opposite phase to the upper one, so that at a distance the effect would hardly be felt. Mr. Preece would no doubt be glad to hear that he was coming round to the opinion that vertical coils might, after all, be the better. Prof. J. J. Thomson had also calculated the effect of vertical coils. If they set up coils vertical to the earth then the conductivity of the earth, instead of hindering, actually helped. Thinking of the matter in the image way, the image of a vertical coil will be in the same phase as itself. He thought vertical coils would be especially good for ship signalling. It had always been a difficult matter to put effective horizontal coils on board a metal ship. Mr. Preece had urged that the best way was to arrange to have the circuit spanning the masts and then use earth plates, and that thus they would get the advantage of earth tapping as well as induction. The disadvantage, however, of a ship fitted up in this way was, that while it could signal broadside on, it could not signal end on. Sir Henry Mance had suggested signalling by two notes; he had evidently meant a system of dots and dashes or right and left signals between two bells, but the following would be more practicable. Suppose a ship was trying to enter a harbour in a fog. On either side of this harbour let there be signalling stations, each with apparatus tuned to a different note, while on board the ship there was apparatus tuned to both these notes. They would hear a musical interval when coming in straight, but if they were to turn the ship a bit they would hear one note increase and the other decrease and when it got exactly end on, one note would stop and the other be heard at a maximum. Then swing the ship till it could hear only the other note. By this means he thought it could take its bearings and find out exactly where it was. With horizontal coils this could not be done. He was much obliged to Mr. Preece for the promised help of the Post Office, for he felt that by working in conjunction with the Government some good work could be done. It now only required a little friendly co-operation and the absence of rivalry to put the matter on a sound basis.

*Mr. W. P. GRANVILLE emphasised the practical side of the question, because he thought it was well for electrical engineers to have some idea of the difficulties that would probably arise in the practical application of wireless telegraphy. First, however, he would like to say something of the work of the late Mr. Willoughby Smith, who had already been referred to at the last meeting by Major-Gen. Webber. On the occasion of his inaugural address, in 1883, Mr. Smith had described a large number of experiments made by him on magnetic induction, and the speaker exhibited and explained some of the original diagrams Mr. Willoughby Smith had used on that occasion. Mr. Smith had suggested, at that time, the use of magnetic induction as a means of telegraphing with trains in motion, and also for other purposes where ordinary telegraphy could not be utilised. The idea had not been very well received at the meeting, but times had changed since then. During the last 10 years Mr. Willoughby Stathan Smith and himself had had the task before them of devising some method which would be suitable for telegraphing to those places, which would be impracticable by ordinary means, such as outlying rock lighthouses, and they had made a large number of experiments in the laboratory, and also at the Needles Lighthouse in Alum Bay. The results were such that they had since devised a system which, in conjunction with the Royal Commission on lighthouse communication, had been established at the Fastnet lighthouse. The tower of the lighthouse was built of boiler plate, although it was lined with brick, and everything around it was of a conducting nature. In fact, the rock itself was the only non-conducting body for eight miles round. It was very clear that in a case of this sort it was absolutely impossible to employ the methods they had heard explained in the Papers. They heard about the installation at Flat Holm which required a circuit base of something like a quarter of a mile, but here was a case where no base was available. Then they came to the case suggested by Mr. Evershed of a coil. But a coil would never last in the rough sea around the lighthouse. They laid a cable and anchored the end in 12 fathoms of water in the near vicinity of the rock, and by sea leakage they picked up the shunt current from the rock, and, by means of a suspended coil galvanometer, they effected communication. They were still in a more or less temporary condition, although daily messages were exchanged by the lightkeepers with the shore. The rock was of granite hardness, and they had taken about four months to cut a chase down the side of the rock to lay one of the earth lines in, and yet it was washed out soon afterwards. So the object had been accomplished by drilling down through the rock with a diamond drill. Coming to the Papers he drew attention to the statement made by Dr. Lodge that the whole matter, whether wireless telegraphy was aided by induction or conduction, might be settled by experiments, but that in certain cases such experiments would be absurd. Was that necessarily so? If they had one coil with no earth, was it absurd to consider that another coil with an earth on would not possibly pick up the current by conduction? Was it not true that the inducing coil would induce currents in the earth which would be picked up by any earthed conductor? Mr. Preece had mentioned in his Paper an experiment in which he first took a length of wire, put it on poles and used it as his sending circuit, and secondly had employed a sending circuit of the same amount of wire made up into a coil, and had found the first form better. In the former case, no doubt, Mr. Preece got the benefit of earth leakage, and after the results of his own experience he had come to the conclusion that whether using Hertzian waves, the coil system or the system at Lavernock, mother earth *did* affect the results very largely.

*Captain BRETT regretted that Dr. Lodge appeared to have discarded Hertzian wave telegraphy. Mr. Evershed had pointed out that the electromagnetic method possessed, as it certainly did, the advantage that calculation was easier. On the other hand, the wave method possessed the enormous advantage that experiment was considerably easier. It was a case of experimenting with a vertical wire in the wave method against transporting tons of copper in the magnetic induction system. He did not think the statement in Dr. Lodge's Paper, that Mr. Preece's system at Lavernock was the only one in actual regular work, could be quite accepted, as Mr. Marconi had for nearly 12 months been exchanging messages between Alum Bay and Bournemouth, a distance of 18 miles, which was

Digitized by Google

nearly six times as far as the existing installation between Lavernock and Flat Holm. The excellence of the messages received over this 18 miles had to be seen to be believed. Also, by Mr. Marconi's method, the problem of communication between lightship and shore had been solved, as the Goodwin lightship had been in uninterrupted communication, since last Christmas Eve, with the South Foreland lighthouse, a distance of over 12 miles. Some of the messages were transmitted during very rough weather, on one occasion when all Channel traffic was stopped. On this occasion, whenever the assistant operating the apparatus on the lightship was *hors de combat*, one of the seamen, who had a slight knowledge of the Morse alphabet, had maintained the communication sufficiently well. Iron masts and wire stays did not make any difference to the clearness of the messages, a fact which he thought would be interesting to the previous speaker on the boiler plate lighthouse. Another interesting item was the fact that the alternators on the South Foreland lighthouse did not affect the system even when the vertical wire was brought to within one inch of the alternator circuit, and also the telephones in the same building were quite unaffected. He thought the speed of the signals of secondary importance. Space telegraphy was not coming to replace telegraphy by wires; it was to facilitate communication where it was not previously possible, and people would not grumble because the rate of signalling was slower. With regard to Dr. Lodge's statement, that earth conduction played a considerable part in coherer signalling, he said that Mr. Marconi had made an experiment during the week on that point, and on the earth connection of the receiver being removed during the receipt of a message, the latter was not interrupted in the slightest. If any change took place it was that the signals were rather more powerful than before. He did not think that earth connection was a necessity of the receiver. It was a necessity to the transmitter for the reason that it seemed to assist in converting the long flaming spark into an oscillating one.

*Mr. DANE SINCLAIR said that the word "earth" had been referred to as a common quantity, that was to say, it seemed to have been taken for granted that the earth behaved at the different places on its surface in a constant manner. From a very long experience of using the earth in a practical way, he found that it varied very much indeed. In practice it would be found that where they were at about the level of the sea with a sandy soil it was almost impossible to get anything like a good earth, while with a clay soil it was almost impossible not to get a good earth. Another point was that to get an earth for two points 50, 60 or 100 miles apart was an easy matter, but to do this for two points, say, half-a-mile apart, was another matter altogether. With regard to the stepping up of the receiver in Dr. Lodge's series of telephones, he thought that if they could get a step-up motion in the reverse way they would have a relay, which for ordinary telephone work would have an immense importance indeed. Perhaps Dr. Lodge had considered it from that point of view.

*Mr. A. C. BROWN thought that right through the discussion it had been well brought out that a low frequency was much the best for transmitting energy, but that a high frequency was better for affecting the most sensitive receivers which were in existence, viz., a telephone or a coherer. Up to the present, however, it had been the custom to use the frequency which was best adapted to operate the receiver, without reference as to whether or no it was the best frequency for transmitting the energy across the space. It did not seem to have occurred to anyone that it might be possible to use both these advantages, viz., that it might be possible to transmit the energy at a low frequency and still retain the advantage of having the receiver affected by the frequency best adapted to operate that; in other words, to split up the received current in these induction telegraphs. Probably this explained the reason why Dr. Fleming had failed to get his signals through a bare wire submerged in water. No doubt he had transmitted his waves at the very rapid rate usual with such apparatus. If Mr. Preece would take his rapid make-and-break out of the primary circuit at Lavernock and put it into the receiving circuit he thought he would obtain still better results, or could overcome a greater distance, provided that no current was produced in the receiving circuit from the current used locally to operate the make-and-break.

*Dr. O. J. LODGE, replying to Mr. Granville's criticism of his statement that experiment was absurd, said that if he used these words he wished to withdraw them. Experiment was never absurd. He only meant to say that he did not expect earth conduction to have any effect if either one of the coils was perfectly insulated. At the same time, he would not deny Mr. Granville's assertion that if only one of the coils was earthed the earth might have some effect. He was much interested in Mr. Granville's statements and photographs about the Fastnet lighthouse. As to his adhering to the subject of his paper, and not diverging on to the cognate subject of telegraphy by means of Hertzian waves, he had been told that Mr. Marconi was down to read a Paper before them this year, and the subject could be discussed then. He had not forsaken it, however, and was continually making experiments, though not on a large scale. Mr. Marconi had much better facilities than he had, and was evidently doing very good work. With regard to the earth connection being of no use for the receiving system, he should be the last to deny that the coherer could be affected direct by Hertz waves, but he knew it could also be affected by pulses coming through the earth. Mr. Sinclair had mentioned that it was more difficult to get earths for small distances than for long ones. It was perhaps not generally known that the resistance of a sphere like the earth was independent of distance. If two small spherical electrodes were introduced in the skin of a sphere, then, whether they were close together or separated by a large distance, the resistance was the same theoretically. Naturally, in a line a thousand miles long the resistance of the earth seemed smaller than with a shorter length.

Mr. SYDNEY EVERSHED, in reply to the discussion, said he did not see that the second correction to his Paper that Dr. Lodge had referred to was necessary. If his statement, that there were 600 times the amount of current available for working a telephone at 400 periods than there was for his relay at 16 periods, was not qualified, it would be absurd, but if they looked at equation 4, which was really the foundation of his Paper, they would find it distinctly stated that the equation referred to that condition in which the electromotive force and the current were brought into phase. The statement with regard to the power did not relate to Lavernock in any way whatever. It was not a part of the Paper that was referring to these experiments, but was a plain statement of the truth that when they had no self-induction, or had neutralised it, and brought the electromotive force into step with the current, the power at 400 periods was 625 times as great as it was at 16 periods per second. He was glad that Dr. Lodge had given them particulars of the power used in his telephone, but unfortunately he had only given them the C^2R losses, and had omitted the most important factor of all, viz., the back electromotive force due to the motion of the diaphragm. What he would have to do was to raise the electromotive force of the telephone, either by re-winding it or by raising its field, until he made the back electromotive force equal to one-half the impressed electromotive force. He would then get the maximum activity. At present he was not doing himself justice. In reply to Dr. Lodge's queries, the Great Sandhead lightship was built of iron, he had put the coil inside the ship, and the primary cable was armoured. The latter had been absolutely unavoidable, as otherwise the cable would not have lasted a week. He felt perfectly confident that the armouring of a cable must necessarily cut off all induction at 400 periods. He had measured the resistance of the armouring, and calculated the inductive effect of it, and found that at 16 periods per second the absorption was 10 per cent. He had made a great many experiments on absorption, but must confess they were entirely fallacious. If they reduced the size of the circuit, they must at the same time increase the specific resistance of their absorbing medium, and the increase in the specific conductivity must be as the square of the scale of the model. When he made his experiments with models, he found that by having a cable ring about a foot in diamete for a lightship, he had to use zinc for his sea. Mr. Whitehead, Dr. Lodge, Mr. Heaviside and Maxwell were all apparently at loggerheads as to how much absorption there would be in any given case. Well, he measured the absorption of this sheet of zinc and compared it with Mr. Whitehead's formula. Mr. Whitehead's figure for the particular piece of zinc that he measured was 38 per cent., while his figure (the speakers) was 27 per cent. Such a difference in a matter of this kind was of no moment whatever. It showed that Mr. Whitehead was on the right track and it gave them an idea of the absorption. If they had taken one of Maxwell's formulæ they would have arrived at a wholly wrong result, because p was given at the top of the fraction instead of at the bottom. Mr. Sennett made some interesting remarks on Mr. Wimshurst's ingenious scheme for communicating with a lightship by means of an induction coil, the primary and secondary parts being the two parts of a swivel, and had wondered why such a thing had never been tried. No such apparatus put into sea stormy would last more than a few days. Since last meeting it seemed that Dr. Lodge had abandoned horizontal coils and left him apparently the sole possessor of them. The question of vertical coils on ships was one which ought to be worked out; it was apparently the only one that would ever work, but the ingenious manner in which Dr. Lodge suggested that a ship would be able to find its bearings was one which he thought likely to break down at the critical moment. In reply to Captain Brett he did not regard induction telegraphy as a thing that would be applicable everywhere; the simplicity of the Hertzian wave system was an immense advantage. But what the cost was, or the expenditure of energy, nobody had ever seemed to trouble about. Mr. Brown seemed to have misunderstood the point of the speaker's experiments at Lavernock. He seemed to imagine that it was leakage that was causing the difference in the received current. It was not so. It was the difference in the leakage current solely, and the extraordinary thing was that the leakage current should fall off so much between a continuous current and 16 periods per second. Therefore, his point was that if it fell off to such an enormous extent between continuous current and a current at 16 periods per second, it might fall off to such a very large extent at 400 periods per second that the result in the telephone would be enntirely due to induction.

A hearty vote of thanks was then passed to Dr. Lodge, Mr. Evershed and Mr. Preece.

CORRESPONDENCE.

INDUCTION TELEGRAPHY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Dr. Lodge has suggested that the result given in my Paper, to which he referred, does not agree with a result given by Maxwell, and that neither agree with one given by Prof. J. J. Thomson. As regards Maxwell's result, from the equations Dr. Lodge wrote on the black-board, I presume he was referring to Maxwell, Vol. II., Art. 798, where the equation is obtained—

$$F = e^{-ps}\cos(nt - qz),$$

provided

$$q^2 - p^2 = \mu K n^2,$$
$$2pq = 4\pi\mu C n.$$

If, however, the frequency is small, $\mu K n^2$ is very small (for a frequency of 300, $\mu K n^2$ is about 4×10^{-15}). So that $q = p$ very nearly. $\therefore p = (2\pi\mu C n)^{\frac{1}{2}}$, which is precisely the result I arrived at.

I regret that I am unable to find in "Recent Researches" the result of Prof. J. J. Thomson, to which Dr. Lodge alluded, so I cannot say why or where we differ.—Yours, &c.,

C. S. WHITEHEAD.

LEGAL INTELLIGENCE.

Stegmann v. O'Connor.

In the Queen's Bench, on Saturday, an appeal from the decision of the Official Referee, in an action brought by Mr. G. Stegmann against a client at Clapham, was heard.

Mr. TINDAL ATKINSON (for plaintiff) said he had to ask their Lordships to set the decision aside because it was against the weight of evidence, and because the Referee's decision was against the contract and specification. In 1898 defendant required an installation put down, and his architect prepared specifications. The contract was given to the plaintiff, and he proceeded to execute it; but a complaint arose that he was not finishing the work in time, and the work was then completed by another engineer. The Official Referee found that the work was not done according to the specification. He allowed plaintiff a certain amount for the actual value of the work taken over by the engineer called in, gave a penalty of £50 for the non-completion, and ordered judgment to be entered for defendant on the claim and counter-claim for £38. 1s. It was in respect of that that the plaintiff now complained. He said he did complete the work. It was true he admitted that in one particular he did not do it according to the specification, but he completed it so that the installation would work all right, and that in the circumstances the Official Referee was wrong in penalising him. The point was, the true construction of the specification. It provided that all the wires were to be encased, and what the plaintiff had to do upon the construction of the specification was to encase the wires in American wood, and then paint the wood so as to prevent decay or corroding. But it was said that he should not have used wooden cases at all, but "compo" cases, and sink them into the walls, because it was said that was a better preservative for the wires. The amount of the contract was £76. 10s.

Their LORDSHIPS pointed out that the casing was to be "proper," and the Referee evidently did not think American wood cases "proper."

Mr. ATKINSON submitted that when "compo" cases were required they were always specified.

The hearing was adjourned.

Hilary Sittings.

The following cases of electrical interest have been ordered for trial at the Royal Courts of Justice during the present sittings:—

COURT OF APPEAL.

Chancery Final Appeals.

Vestry of St. Mary, Battersea, *v.* County of London and Brush Provincial Electric Lighting Co. (Limited). (Appeal of defendants from order of the President of the Probate, Divorce and Admiralty Division, dated April 21, 1898.)

Mica Insulator Co. *v.* Electrical Co. (Limited). (Appeal of plaintiffs from order of Mr. Justice Kekewich, dated June 30, 1898.)

Castner-Kellner Alkali Co. (Limited) *v.* Commercial Development Corporation (Limited). (Appeal of defendants from order of Mr. Justice Bigham, dated August 3, 1898.)

Queen's Bench Final Appeals.

Eastern Telegraph Co. (Limited) *v.* Dent and Others. (Appeal of A. and E. Dent from judgment of Mr. Justice Kennedy, dated June 21, 1898.)

Holliday *v.* National Telephone Co. (Limited). (Appeal of plaintiff from judgment of Mr. Justice Wills and Mr. Justice Lawrance, dated Nov. 29, 1898.)

CHANCERY DIVISION.

Bristol Tramways Carriage Co. (Limited) *v.* National Telephone Co. (Limited). (Action without pleadings.)

National Co. for Distribution of Electricity by Secondary Generators (Limited) *v.* Gibbs. (Action and counterclaim.)

Electric Construction Co. (Limited) *v.* Imperial Tramways Co. (Limited). (Action.)

Cooper *v.* Metropolitan Electric Supply Co. (Action, with witnesses.)

Electric Exploration Co. (Limited.) (Petition of Sussman Electric Miners' Lamp, Limited. Winding up.)

QUEEN'S BENCH DIVISION.

Pearson *v.* Charing Cross, &c., Electricity Corporation. (Defendants' appeal from County Court.)

National Telephone Co. *v.* Day. (Injunction.)

Cooper *v.* Electric Installation Co. (Contract.)

Electric Welding Co. (Limited) *v.* Burdett-Coutts. (Calls.)

Wood Seasoning by Electricity.—A new process, says the *Engineering and Mining Journal*, is announced for seasoning wood by electrical action. The timber to be treated is put into a quadrangular tank of liquid, immersed to rather more than half its depth, and an electric current applied through a metallic conductor, so arranged as to distribute it throughout the area, and it is stated that in a space of four minutes the sap begins to exude at the lower end of the wood; in six hours it is all extracted. The wood is then placed in another tank from which a sceptic solution is forced into the pores "by an electro-capillary method."

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

NEW BOOKS AND EDITIONS.

The following New Books and Editions can be obtained of the Booksellers or direct from the Publishing Offices, 1, 2 and 3, Salisbury court, Fleet-street, London:—

NOW READY.

"ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS."—By J. Elton Young, M.I.E.E. The scope of the book aims at furnishing a fuller treatment of the subject, from the standpoint of the Telegraph Engineer, than it has hitherto received, whilst it endeavours to facilitate a thorough comprehension of the theory of testing as applied to electrical lines in general. The Author hopes that, besides Telegraph and Telephone Engineers, it may, perhaps, also prove of service to those in charge of cables for the transmission of light and power. The localisation of faults has been very fully investigated, including the different degrees in which the various methods are affected by the presence of a second fault or of general leakage.—*Extract from Preface.* Demy 8vo, fully illustrated. 10s. 6d., post free; abroad 11s.

"SUBMARINE CABLE-LAYING AND REPAIRING."—By H. D. Wilkinsor, M.I.E.E., &c., fully illustrated; price 12s. 6d.

"THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING."—A new work by Messrs. H. K. C. Fisher and J. C. H. Darby, with the above title, is now ready, price 6s. net; abroad, 6s. 3d. This work is intended to serve as a guide to operators already in the telegraph service, and to those who desire to enter that service. The great cable companies now insist that their operators and probationers shall pass certain examinations in electrical subjects. The book is very fully illustrated. *Second Edition now ready.*

"PRACTICAL NOTES FOR ELECTRICAL STUDENTS."—By Messrs. A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free.

"ELECTRO-CHEMISTRY."—By Dr. G. Gore. Third Edition. Price 2s, post free.

"WIRELESS TELEGRAPHY: SIGNALLING ACROSS SPACE WITHOUT WIRES BY ELECTRIC WAVES."—By Dr. O. J. Lodge, with many original illustrations. *Enlarged Edition*, 2s. 6d. net, 2s. 9d. post free.

"ELECTRIC MOTIVE POWER," by Albion T. Snell, contains the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d., post free; abroad, 11s.

"LABORATORY NOTES AND FORMS."—With the above title we have ready the New Edition of a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators and Students. The object of this series is the saving of the time of the Teacher and his Assistants, and to serve as a record of the work done by the Student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen net; in sets of any three, 1s. net; or the set of Twenty (Elementary or Advanced) Exercises can be obtained, price 5s. 6d. net. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. net; or in handy portfolio, price 12s. net; or bound in strong cloth case, price 12s. 6d. net. Strong portfolios can be had, price 1s. each.

NOW READY.—The cheaper edition of Dr. J. A. Fleming's "Electrical Laboratory Notes and Forms." These cheaper Forms have been prepared for the use of students and teachers at the Polytechnic and other science classes throughout the country. The demand for the original set of these Notes and Forms has led to a request for a cheaper set for use at the day and evening classes at many of the technical institutes. These new Forms, which differ only from the higher-priced set in being printed on smaller and cheaper paper and with less space for tabulated records, are issued at half the price of the original set.

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready. Price 7s. 6d.; abroad, 8s.

"THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS."—Edited and enlarged by W. Worby Beaumont. Price 3s. 6d., post free.

"THE ART OF ELECTROLYTIC SEPARATION OF METALS."—A second issue of Dr. Gore's book is now ready, price 10s. 6d., post free.

"THE MANUFACTURE OF ELECTRIC LIGHT CARBONS."—A Practical Guide to the establishment of a Carbon Manufactory. Fully illustrated. price 1s. 6d.; post free, 1s. 9d.

"THE BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH, 1896-97.' A valuable, up-to-date compilation. Being an attempt to classify the data relating to X-Ray work. This work contains a quantity of general as well as special information bearing upon the whole subject of electrical discharge research. Price 5s., post free; abroad, 5s. 3d.

"LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS."—By F. C. Raphael. Price 5s., post free; abroad, 5s. 6d. Prospectus on application.

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book, by Messrs. W. Geipel and H. M. Kilgour; price 7s. 6d.; by post, 7s. 9d.; abroad, 8s. A fine large paper edition with wide margins for notes can also be supplied. Price 12s. 6d.; post free, 13s.; abroad, 13s. 6d. *New Edition in the press.*

"THE ALTERNATE CURRENT TRANSFORMER," Vol. I.—By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. *New Edition.* Price 12s. 6d., post free. Vol. II., price 12s. 6d. post free, is also ready.

"ELECTROMAGNETIC THEORY."—By Oliver Heaviside. Vol. I., price 12s. 6d.; post free, 13s.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free.

"THE ELECTRICIAN" PRIMERS.—In Two Volumes. Vol. I., Theory. Vol. II., Practice. Price, stout paper cover, 2s. 2d. each, post free; cloth, 2s. 9d. Single Primers, 3d. each, post free.

Digitized by Google

"ARMATURE WINDINGS OF ELECTRIC MACHINES."—By H. F. Parshall and H. M. Hobart. This work has been compiled from notes made by Mr. Parshall in his capacity as Chief Designing Engineer of the Edison and General Electric Companies of America, and is intended to serve as a working treatise on dynamo design. Large 4to, 370 pages, 140 full-page illustrations and 65 full-page tables, 30s., post free.

"DRUM ARMATURES AND COMMUTATORS," by Mr. F. Marten Weymouth, also ready. Price 7s. 6d.; abroad, 8s. Prospectus on application.

"THE POTENTIOMETER AND ITS ADJUNCTS": A Universal System of Electrical Measurement.—By W. C. Fisher. Fully illustrated. Price 6s., post free; abroad, 6s. 6d. Digest post free.

"MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY."—By E. Tremlett Carter, C.E., M.I.E.E. Price 12s. 6d., post free; abroad 13s. 6d. Prospectus post free.

"The Electrician" Electrical Trades' Directory and Handbook.—An important announcement in connection with the 1899 issue of the "Big Blue Book" will be found in an advertisement on another page of the present issue, to which our readers will please refer.

Electricity Supply Data and Statistics.—In the large sheet tables of electricity supply statistics issued with *The Electrician* for Jan. 6 there were some omissions which we hope to remedy in the final issue of the tables the first week in February, when the tables will form part of "The Electrician" Electrical Trades' Directory and Handbook for 1899, and will also be obtainable on rollers and in cloth cases. The Editor will be obliged if station engineers and others who can assist in completing the table will send in particulars as to: (1) The total capital expenditure to Dec. 31, 1898 (actual or approximate); (2) The total units generated for year to Dec. 31, 1897 (actual); (3) Units generated for year to Dec. 31, 1898 (actual or approximate); (4) Any other particulars which will help to make the table fully complete to Dec. 31, 1898. It is hoped that the information sought will reach *The Electrician* office by Jan. 26.

TENDERS INVITED.

The Electrical committee of the *Whitechapel* (London) District Board of Works invite tenders for the supply and erection of:—(*a*) Armoured and unarmoured cables; (*b*) arc lamps and posts; (*c*) steam dynamo and balancing booster; (*d*) storage batteries; (*e*) boilers and fittings, feed pumps, pipes and heater. Specifications can be obtained from Mr. Arthur Wright, 26 and 27, Bush-lane, Cannon-street, London, E.C., after the 27th inst., and tenders must be sent to the clerk of the Board (Mr. Alfred Turner), 15, Great Alie-street, London, E. Further particulars are given in an advertisement elsewhere.

The *Buxton* District Council invite tenders for the supply of feeders, mains and arc light heads. Copies of specifications, &c., may be obtained from Mr. Josiah Taylor, Town Hall, Buxton, and specifications and drawings may be seen at, but not obtained from, Prof. A. B. W. Kennedy, 17, Victoria-street, London, S.W. Tenders must be sent in to Mr. Taylor by Monday, Feb. 6. An advertisement elsewhere gives further particulars.

The *Burton-on-Trent* Corporation invite tenders for the supply and erection of three steel Lancashire boilers at the electric light works. Copies of conditions, specifications, &c., may be obtained from Mr. F. L. Ramsden, Gas and Electric Light Works, Burton-on-Trent. Further particulars are given in an advertisement, and tenders must be delivered to the town clerk (Mr. T. N. Whitehead) by 10 a.m. of Saturday, 28th inst.

As announced in an advertisement, the Electricity committee of the *Belfast* Corporation invite tenders for the supply of the following:—Cast iron pipes, cast iron frames and covers, earthenware conduits, insulated cable, and Lancashire boilers. Specifications and conditions of contract may be obtained from Mr. Victor A. H. M'Cowen, city electrical engineer. Tenders must be lodged with the town clerk (Sir Samuel Black), City Hall, Belfast, by Thursday, Feb. 2.

The *Metropolitan Asylums Board* invite tenders for the supply and erection of the following electric lighting plant at the Northern Hospital, Winchmore Hill, N.:—(1) Switchboards, booster and connections; (2) battery; (3) electric mains; (4) steam exhaust, feed and drain pipes; and (5) wiring and fittings. Tenders must be lodged at the office, Norfolk House, Norfolk-st., London, W.C. by 10 a.m. of 25th inst.

The Commissioners of *Govan* invite tenders for the supply and erection of (1) water tube boilers and feed heater; (2) engines and dynamos, equalising transformer, boosters, &c.; (3) lead-covered armoured cables; (4) storage batteries; (5) arc lamps; and (6) arc lamp pillars. Tenders to Mr. A. Macdonald, Hillock House, 752, Govan-road, Govan, by 23rd inst.

The Corporation of *Lowestoft* invite tenders for the supply and erection of the following plant:—(*a*) boilers and fittings, economisers, feed pumps, &c.; (*b*) pipe work, &c., for engine and boiler house; (*c*) steam dynamos and motor boosters; (*d*) storage batteries; (*e*) main switchboard and connections; (*f*) overhead travelling crane; (*g*) underground mains and conduits, road work, &c.; (*h*) arc lamps and posts; (*i*) station lighting. Tenders to the Town Clerk, at the offices, 115, High-street, Lowestoft, by noon of Feb. 6.

The Commissioners of the Burgh of *Stirling* invite tenders for supply of mains. Tenders to Town Clerk's Office, Stirling, by 30th inst.

The *Sunderland* Corporation require tenders for road work with stoneware casings, and supplying and laying cables. Tenders addressed to chairman of the Lighting committee, Town Hall, Sunderland, must be sent to Mr. Fras. M. Bowey, by 27th inst.

The *Ealing* (London) Council require tenders for two 500 H.P. steam alternators, and one 150 H.P. steam dynamo alternator. Tenders to clerk, Ealing, W., by 30th inst.

Tenders are required for an electric light installation, including boilers and accumulators to 150 H.P. Particulars from Mr. H. Cleaver, engineer, 52, Bridge-road, *Southampton*.

The *Halifax* Corporation invite tenders for a 600-kilowatt steam alternator. Tenders to the Town Clerk by noon of 24th inst.

The *Hull* Corporation invite tenders for a water softener for dealing with 400 gallons per hour and three steel tanks for the tramways department. Tenders to Chairman of Works committee by 25th inst.

The *Bradford* Corporation invite tenders for electric lighting their Hammerton-street destructor works. Tenders to town clerk by Feb. 1.

Tenders are invited by the Directors of the *General Accident Insurance Corporation* for the supply of electric bells and telephones at their new offices, Tay and High-streets, Perth. Particulars from Mr. G. P. K. Young, 42, Tay-street, Perth.

The *Rathmines and Rathgar* District Council invite tenders for the erection of electricity station buildings and foundations. Tenders to Chairman, Town Hall, Rathmines, Dublin, by 30th inst.

The *London* County Council invite tenders for four continuous-current dynamos, one motor generator, two switch-boards with switches, measuring instruments and other work required for the proposed Victoria Embankment electric generating station. Tenders to Mr. C. J. Stewart, County Hall, Spring-gardens, S.W., by 10 a.m. Jan. 31.

The *Norwegian* State Telegraph Administration are inviting tenders for the delivery of about 140,000 porcelain telegraph and telephone insulators. A copy of the specification, conditions, &c., can be seen on application at the Commercial Department of the Foreign Office, and tenders must be sent in to the Administration at Christiana by 12 noon of Feb. 26.

The *London* County Council also require tenders for the erection of four gas engines at the proposed Victoria Embankment electric generating station. Tenders by 10 a.m. Jan. 31.

Tenders are invited by the municipal authorities of Merbes-le-Château, *Belgium*, for the electric lighting of the town. Particulars can be had from Le Bourgmestre.

TENDERS RECEIVED AND ACCEPTED.

The Shoreditch Vestry received the following tenders for the supply and fixing of three 66 kilowatt and three 33 kilowatt transformers and switch gear:—

	Six transformers.	66 kilowatt armature.	33 kilowatt armature.	Long-range switch.
Electric Construction Co. (*accepted*)	£4,497	£270	£185	£65
Thomas Parker (Limited)	4,914	250	180	50
Brush Co.	5,388	420	230	79
Mather and Platt	*3,870	270	185	—

*Not including switch gear, estimated at £1,000.

The contract for supplying and erecting an electric lift at the new Y.M.C.A. Buildings, Newcastle-on-Tyne, has been placed with the Otis Elevator Co., and Messrs Bland Bros. have obtained the contract for wiring and supplying ventilating fans, &c.

On the recommendation of the Electricity and Public Lighting commitee the St. Pancras Vestry have accepted the quotation of the Brockie-Pell Arc Lamp (Limited) for the supply of 50 Brockie-Pell arc lamps at £8. 15s. each.

The tender of Messrs. Johnson and Phillips has been accepted by the Southport Corporation for the supply of two 60-kilowatt transformers at £110 each.

The Electric Lighting committee of the Edinburgh Town Council on Tuesday accepted the tender of Messrs. Mather and Platt for the supply of electric lighting plant at the Macdonald-road station at £9,136.

The Electricity committee of the Bolton Corporation have accepted the tender of Messrs. Hick, Hargreaves and Co., for two electric feed pumps, and that of Messrs. Musgrave and Son for a new water tank and a new travelling crane for the electricity works.

Digitized by Google

APPOINTMENTS VACANT AND FILLED.

The Torquay Corporation require a mains electrician for their electricity department. Applications must be sent in by Saturday, 28th inst., to the Corporation electrical engineer (Mr. P. Storey), Electricity Works, Torquay. See advertisement.

A resident electrical engineer is required at the Mullingar (Ireland) District Asylum. Salary £60, with board, &c. Applications to the medical superintendent. See advertisement.

The Worcester Corporation require two improvers as switchboard attendants. There are also vacancies for two pupils at the electricity works. Applications to city electrical engineer (Mr. C. J. Sutherland). See advertisement.

A switchboard attendant is required at the Morecambe electric light works. Applications by the 24th inst. to the electrical engineer (Mr. C. F. Parkinson, M.I.E.E.). See advertisement.

The Great Indian Peninsula Railway Co. require an assistant telegraph superintendent. Applications have to be sent to "C.E.," 5, Victoria-street, Westminster, London, S.W. See advertisement.

A mains superintendent is required for the Southport electricity works. Applications to town clerk by Wednesday next.

An electrical tester and an improver are required by the South Shields electricity department. Applications by 28th inst. to borough electrical engineer.

A second assistant engineer is required for the Ashton-under-Lyne electricity works. Applications to borough controller by 30th inst.

Mr. F. W. Clements, having resigned the position of resident engineer at the St. Luke's station of the County of London and Brush Provincial Company to accept an important post in Australia, is succeeded by Mr. W. J. Dale, promoted from the company's Wandsworth station. Mr. A. A. Whitlock, late resident engineer at Dover, succeeds Mr. Dale as resident engineer at Wandsworth, and Mr. L. W. Woodman, late chief assistant at Dover, has been appointed resident engineer at Dover, Mr. T. W. Bloxam becoming first assistant at that station. At Coatbridge, Mr. J. B. McIndoe has been appointed resident engineer, succeeding Mr. G. C. Laird, now first assistant to Mr. Teague at Paisley. At Wandsworth, Mr. A. R. Bacon becomes first assistant-engineer, Mr. C. Carew-Gibson second, and Mr. W. G. Hardy third.

Mr. C. R. Bellamy has been appointed general manager of the Liverpool tramways, at a salary of £800 per annum, rising by annual increments of £100 to £1,000. Mr. M'Kenna has been appointed assistant manager, at a salary of £300.

Mr. James Keith, B.Sc., has been appointed chief electrical engineer to Messrs. Tuck and Co. (Limited), Dublin.

Mr. G. R. Hulme, of the Blackpool Electricity Department, has been appointed secretary of the Blackheath and Greenwich District Electric Light Co. (Limited).

Mr. E. J. Scown, C.E., assistant borough surveyor of Huddersfield, has been appointed engineer to the tramways department of the Manchester Corporation. Mr. Scown commences his duties on 6th prox.

Mr. A. G. Bird has been appointed assistant electrical engineer at Bristol, at a salary of £175 per annum. Mr. Bird has recently been with the Yorkshire House-to-House Electricity Co.

Mr. George G. Scurfield, of Sunderland, has been appointed assistant engineer at the Carlisle electricity works.

BANKRUPTCIES, LIQUIDATIONS, &c.

A receiving order has been made against Thos. Ford, trading as Thos. Ford & Co., electric fittings, &c., maker, The Retreat, Selly Park, Worcs., and Victoria Works, Emily-street, Highgate, Birmingham.

In the bankruptcy of Chas. Leigh Clarke, electrical engineer, Hope-road, Newton-le-Willows, trading at 7, South Parade, Manchester, as the Northern Counties Electric Construction Co., the trustee (Mr. W. A. Smith), 17, Cooper-street, Manchester, has been released.

The Britannia Motor Carriage Co. (Limited) is to be wound up voluntarily, and the Hon. J. H. H. Berkeley, Throgmorton House, London, E.C., has been appointed liquidator. The company's undertaking has been acquired by the London Exploration Co.

It has been decided to wind up the Direct Telephone Exchange Syndicate (Limited) voluntarily and to appoint Mr. T. Featherstone-Smith, 8, Minories, London, E.C., liquidator.

The creditors of Jacob Gutmann (trading as J. Goodman and Co., electrical supplies dealers, 48, Commercial-street, London, E.), met yesterday (Thursday) at the offices of Messrs. Lovering and Newstead, trustees, 3, Church-passage, Guildhall, E.C. The meeting was called to receive the trustee's and solicitor's reports, and to consider the advisability of further investigating the affairs of the debtor. Mr. Osborne, who presided, said that the trustee had been making inquiries in regard to certain important items in connection with this failure. In June last, a month before the filing of the petition, the debtor assigned the whole of his estate to Goodman and Co., Ltd., and received 4,000 fully-paid shares in exchange, the debtor's explanation of this peculiar transaction being that "it was done to protect his estate." Gross liabilities are £3,850, out of which trade creditors stand to lose £3,733. The whole of this loss was incurred between December, 1897, and July, 1898, and (observed Mr. Osborne) no trace whatever can be found as to the disposal of the goods obtained from creditors. No proper books of account had been kept. The disappearance of the goods was only to be accounted for by one clue which had been unravelled in investigating the matter, and this clue led to others of a somewhat sensational and suggestive character. It was clear that the debtor only made over to the company a very small quantity of goods and no money whatever. The debtor appeared to have recently become connected with a dealer in electrical accessories and sundries, and the creditors would have to look closely into this connection, and into an item amongst the liabilities of £1,450 alleged to be due to a man named Barnes, in whose employ (Mr. Osborne observed) Goodman now is. The trustee reminded the creditors that there were no available assets in this case. A letter from the solicitors suggested a consultation of the creditors and the solicitor to the estate to see if some course of action could be decided upon to lead to a full investigation of the debtor's affairs. This was for the creditors to decide, because the preliminary cost of a prosecution would have to come out of the creditors' pockets, although the Public Prosecutor would relieve them of all further expense if he approved of action being taken after the facts had been put before him. The replies of the debtor to questions by the chairman were considered most unsatisfactory, and the meeting ultimately (on the motion of the Phaeton Electrical Co., seconded by Messrs. R. S. Keep and Co.) agreed—"That the trustee be instructed to take further steps to investigate the affairs of this debtor, and that the creditors be asked to contribute a sum of 1s. in the £ on account of their respective debts towards the preliminary expenses of such investigation." The meeting then adjourned.

Business Notice.—The Wireless Telegraph and Signal Co. (Limited), have taken a factory in Chelmsford for the manufacture of instruments and apparatus connected with the company's system.

To Let.—Messrs. Willis Bros., auctioneers, Gloucester, announce in an advertisement that they have premises suitable for electrical engineers and others to let in the centre of the city of Gloucester.

Exhibition.—The Executive Council of the Glasgow International Exhibition (1901) notify in an advertisement elsewhere that they are now in a position to receive applications from electrical and general engineers and others who propose to exhibit. Particulars can be obtained from the engineer (Mr. Thomas Young), 4, West Regent-street, or the general manager (Mr. H. A. Hedley), 141, Buchanan-street, Glasgow.

"**Electric Wiring Practice**" is the title of a Paper, by Mr. F. Bathurst, A.I.E.E., which deals with "the present practice and probable development of the art of electric wiring." Mr. Bathurst points out that there are in operation or in progress in this country more than 200 electricity supply stations, and that, therefore, the subject of interior electric wiring is a matter of concern to all actual and potential consumers of electric current for interior lighting. The object of the publication of the paper is to bring before architects, consulting engineers and electrical contractors the advance shown by the introduction of the Conduit and Insulation Co.'s system of steel armoured insulating conduit. The paper is issued in pamphlet form and can be obtained, free of charge, by any person interested in the subject. Mr. Bathurst, and those who think with him, urge that, in order to make electric wiring thoroughly effective, durable and permanent, it is necessary that a perfect mechanical and electrical protective duct should be provided for the whole course of the wires, capable of withstanding injury from any and all outside conditions; and he claims that the special type of conduit manufactured by the Conduit and Insulation Co. fully meets this up-to-date requirement. As evidence of the advance in public favour which this type of conduit is meeting, Mr. Bathurst points to the fact that although steel armoured conduits are the highest in price of any conduit on the market, there is a steadily extending use of this material in installation work in this country, and this report confirms information received from other firms engaged in this branch of the electrical industry. Among many installations in which the Conduit and Installation Co.'s conduit system has been adopted may be mentioned:—Kensington (London) Town Hall; Brighton Town Hall; Bridgwater House Picture Gallery, Pall Mall, London; Technical Schools, Brighton; Hyde Technical Schools, Manchester; New Guildhall School of Music, London; Stafford County Infirmary; Middlesex Hospital, London; St. Andrew's Hospital, Northampton; Victoria Nurses' Home, Bradford; Ayr Brewery, Scotland; St. Luke's (London); Islington (London); Knightsbridge (London) and Southampton Electricity Works; Liverpool Grain Storage Co's Docks and Ware-

Digitized by Google

houses; J. Barker and Co.'s Stores and Harrod's Stores (London); Law Union and Crown Life Insurance Buildings, Manchester; Royal Insurance Co.'s Buildings, Glasgow; Sir J. Causton's New Printing Works, Clapham; Anglo-Caucasian Oil Co. Works, Silvertown; Queen's Docks, Glasgow; Jewish Synagogue, Cardiff; Board of Trade Laboratory, Whitehall; New County Offices, Wakefield; Municipal Chambers, Glasgow; and a number of famous country seats, theatres, restaurants, &c.

Ediswan Leaflets.—The Edison and Swan Co. have just issued leaflet No. 120 describing and illustrating Capt. Walter's patent night light switch, which can be fixed in the place of any existing switch and ensures an economic use of current during night hours. Leaflet No. 111 is also to hand graphically illustrating and describing Ediswan ball fittings for various uses.

Calendars.—Messrs. Nalder Bros. and Thompson forward a useful pad calendar for 1899, copies of which can be obtained by the trade on application.

Local Government Annual.—We have to acknowledge from the office of the *Local Government Journal*, Dorset-street, Fleet-street, London, the 1899 "Local Government Annual and Official Directory," which contains a large amount of information of service to firms in business relation with the local authorities of London and the provinces. The price of the book, bound in cloth, is 2s. 6d.

Telephone Directory.—The January, 1899, Supplement to the Telephone Directory (with additions, alterations and corrections) is to hand from the National Telephone Co.

Babcock-Wilcox Boilers.—What is probably the largest order for stationary boilers ever given out was placed, during the month of December, with the Babcock and Wilcox Co. in New York on behalf of the Westinghouse Electric Co., Pittsburg. The order was for 60 boilers, each of 1,000 I.H.P. The boilers will be made in America, but the bulk of the wrought steel from which they are to be constructed will be sent out from this country.

The "Universal" Engine.—The Brush Co. are sending out a well-illustrated pamphlet describing the chief features of Raworth's Patent "Universal" steam engine. The text includes instructions on erecting and starting the engine, and also for connecting and operating the "Garagon" steam lubricator.

Electric Heating Apparatus.—We are informed that the English Industrials (Limited), of Manchester, have purchased from Messrs. Hummel and Helberger the sole rights for the United Kingdom and the colonies of Patent No. 13,594, relating to electrical heating apparatus and various acccessories in connection therewith. A high degree of efficiency is claimed for this apparatus.

Soldering Paste.—We have received from Messrs. Beanland, Perkins and Co. a sample tin of Burnley's rozinal soldering paste, which resembles vaseline in appearance. It is claimed that this material forms a better flux than ordinary rosin, with the advantage of being easier to manipulate.

Exports of Electrical Apparatus and Material.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from Jan. 11 to Jan. 17, with the ports of destination:—

Australasia—Adelaide, £44; Lyttelton, £35; Melbourne, £360 (telegraph material); Sydney, £653. *Belgium*—Ostend, £23. *Brazil*—Rio de Janeiro, £80. *Burma*—Rangoon, £31. *Ceylon*—Colombo, £27. *China*—Shanghai, £89. *Denmark*—Copenhagen, £17. *France*—Boulogne, £76. *Germany*—Bremen, £50; Hamburg, £110. *Gibraltar*—£33. *Holland*—Amsterdam, £30. *India*—Bombay, £545 (including £35 telegraph material); Calcutta, £763. *Japan*—Hiogo, £12; Yokohama, £562. *Malta*—£75. *Norway*—Christiania, £360. *Russia*—Helsingfors, £357 (telegraph wire); Reval, £126 (including £71 telegraph material). *South Africa*—Cape Town, £544; Delagoa Bay, £28; Durban, £705; East London, £377; Port Elizabeth, £18. *Spain*—Barcelona, £33; Santander, £11. *Straits Settlements*—Singapore, £927. Total £7,101, against £5,951 in the corresponding week last year (Jan. 12 to Jan. 18).

MUNICIPAL, FOREIGN AND GENERAL NOTES.

Aberdeen.—A discussion arose at the meeting of the City Council this week upon the advisability of equipping the Woodside tramway route on the overhead trolley system, but it was decided, before coming to a decision, to send a deputation to Glasgow and other places where electric tramways are in operation.

Acton (Middlesex).—The District Council seem disposed to take a supply of electricity in bulk from the Metropolitan Electric Supply Co.'s new station at Willesden and negotiations are proceeding as to terms. The company offers current at 3d. per unit for seven years.

Asuncion (Paraguay).—Mr. N. Sellers has obtained a concession for establishing electricity supply works in this city.

Brazil.—We learn that the San Paulo Gas Co. have decided to at once erect electricity supply works for the supply of current for lighting and power purposes. The company have entered into an agreement to light the new railway stations in course of erection in Sao Paulo. The company has, we understand, decided upon this course because of the strong position they hold with the new concession for 30 years. The company's consulting engineer has been instructed to prepare the plans and specifications and obtain tenders for carrying out the work with the least possible delay.

Brecon.—The Mayor, Col. Morgan, has decided to erect electric lighting works in the town.

Bristol.—There is at present an equivalent of about 64,000 8 c.p. lamps connected to the electric lighting mains, and there are in hand applications for another 7,000. The capacity of the station when the present extensions are completed will equal 80,000.

Brussels Telephone Service.—There will shortly be opened in Brussels a spacious building exclusively devoted to the telephone service of Brussels. The building, which will provide accommodation for the connection of 15,000 subscribers, is situate in the old quarter of the town, and has cost nearly £40,000. The building comprises a basement, ground floor and three storeys, and the main room is 147ft. in length, 65ft. wide and 30ft. high, and one floor of large dimensions is reserved exclusively for the use of the telephoning public. By the time the building is open the entire service will be on the twin-wire system. It has been decided to place nearly all the telephone wires of the service underground. The d'Anthonay heating system has been adopted, and is worked by a 3 H.P. gas engine operating a turbine, which forces cold air into the heating apparatus, and is claimed to reduce to a minimum the amount of moisture and dust resulting from overheating and bad ventilation. It is claimed for this particular system that it is as effective for providing cool air for the summer as for heated air in the winter.

Cape Colony.—By a recent order of the Government at the Cape the rebate on imported goods passing through the colony to the inland states has been reduced from 5 per cent. to 3 per cent., the reduction applying to the South African Republic, Orange Free State and Rhodesia. The new law will affect electric cables and wires and posts for same and their fittings, electric lamp posts and their fittings, electric lamps and switches (*excluding* fancy and ornamental switches and fittings for indoor lighting); tramway equipment requisites (cars, trolleys, water tanks and turntables); wires, bells and gongs for signalling and for use in and about mines (on which rebate will be allowed on the whole customs duty). The following articles are admitted free of duty under the customs union tariff on importation into Cape Colony, irrespective of their ultimate destination:—Machinery to be driven by electricity and apparatus and appliances used in connection with the generation and storage of electric current (but not including electric cables, wires, posts, lamps and switches previously mentioned); railway and tramway construction or equipment requisites (rails, sleepers, fastenings for same, girders, iron bridge work, locomotives, tenders, trolleys or other articles not previously enumerated); and telegraph materials for use in construction of telegraph lines.

Chatsworth.—On the occasion of the recent county ball given at Chatsworth by the Duchess of Devonshire several hundreds of additional electric lamps were fixed in the ball room, orangery, statue gallery and other parts of the building by Messrs. Drake and Gorham, who have carried out all the electrical work at this famous country seat.

City of London Lighting.—A report from Mr. A. A. Voysey electrical inspector to the London Corporation, states that in the main streets there are 493 arc lights. The total number of lamp failures in the past year had been 1,466, the average time of extinction per lamp being 236 minutes. A sum of £352 had been paid in penalties by the City of London Electric Lighting Company for failures and lateness in starting. Arrangements for testing the supply of electricity to the public lamps had not yet been made. The company, who were responsible for the provision of instruments at their own expense, were now in communication with the Board of Trade as to their requirements, the instruments being subject to the Board's approval. The private electric supply amounted to an equivalent of nearly 300,000 8 c.p. lamps.

Datchet.—The Council have expressed themselves willing to consider any practical scheme for providing the parish with the electric light, and offers to support the application of the Slough and Datchet Electric Light Co. for a provisional order.

Dawlish.—The District Council have invited Messrs. Taylor and Field to state their terms for preparing a report on the electric lighting question.

Electric Motor Cab.—A Press view was given last week of the Krieger electric cab, which has been introduced by the Motor Car Co. The vehicle is well known in Paris, but has not yet been adopted there or elsewhere as a public conveyance. It carries twice as many passengers as the electric cabs with which we are now so familiar in London, and it is claimed that a single charge is sufficient to take the vehicle 60 or 70 miles.

Digitized by Google

Devonport.—The Town Council have decided to purchase a site for electricity supply works.

Dynamo Electric Machinery Exports.—For the year 1897 Japan imported dynamo electric machinery to the value of nearly £104,000, of which Great Britain supplied £18,500, the United States about £68,500, and Germany about £17,000. These figures show a considerable increase over 1896 and 1895, except in the case of Great Britain, whose exports decreased from £26,500 value in 1896 to £18,500 in 1897.

Edinburgh.—The Town Council have asked the Electric Lighting committee to report on the necessity for laying aside a sum either by renewal fund or otherwise for renewals of the electric light plant.

Electricity v. Gas.—Interesting figures have just been issued as to the relative cost of electric *v.* gas lighting at the School Chapel, Harrow. The average cost of lighting by gas in 1893, 1894 and 1895 was £20. 1s. 8d., and the average cost of lighting by electricity (with additional lights under the organ loft in the south aisle) in 1897 and 1898 was £17. 10s. Meter rent was included in each case. The price of electric current at Harrow is 8d. per unit, gas 4s. 3d. per 1,000ft.

Fatality.—A sad drowing fatality occurred on the 15th inst., near Porthcurnow, the Eastern Telegraph Co.'s station near Penzance. It seems that, notwithstanding the heavy weather, a party of telegraphists from the station decided to bathe in the sea at Penberth, a sheltered cove. The swell of the sea was, however, unexpectedly severe, and one of the party, a young man named Laing, was thrown against the rocks and rendered insensible. Assistance was promptly rendered, and he was landed, but not before death had taken place by drowning. Mr. Laing was a native of Exeter.

German Electrical Industries.—In a report on the foreign commerce and industrial progress of Germany for 1897-98 presented to the United States Government by the American Consul-General at Frankfort, the following notes on the development of German electrical enterprise occur:—The electrical manufacturing companies worked literally night and day during 1897 for months of phenomenal activity. The Allgemeine Elektricitäts Gesellschaft, of Berlin, entered upon 1898 with orders on its books representing £5,000,000 in value, against £3,250,000 on Jan. 1, 1897. The Schuckert Co., of Nuremberg, had in June, 1897, orders on hand representing nearly £5,000,000, or more than double the orders on hand at the same date in 1896. Particular attention is called to the large amount of capital invested in the manufacture of calcium carbide. The market for German electrical appliances has obtained almost a monopoly in Eastern Europe. In Turkey electric lighting is being carried on almost exclusively by German contracting firms, and at Kalamata (Greece) an electric lighting station has been equipped for the municipality by a German house. At Kalamata also Messrs. Hiedemann and Co., of Colbgne, have constructed an electric railway to the harbour of Kallivia.

Glasgow.—The High-street extension of the electric tramways will be opened for traffic next week.

Gloucester.—A Local Government Board inquiry was held here on Wednesday into the application of the City Council for authority to appropriate funds from the sale of corporate property for the purchase of a site for electric liphting works. There was no opposition.

Grimsby.—The Town Council agreed at their meeting, last week, to apply for sanction to borrow £43,000 for the erection of electricity supply works.

Halifax.—The Commercial-street-Salterhebble electric tramway extension is approaching completion. The Board of Trade inspection takes place next week.

Hanley.—The Town Council have decided, in consequence of the resignation of Mr. Sutherland, who was until recently joint engineer with Mr. Cowell, of the electricity supply works, to appoint the latter gentleman to the post of Corporation electrical engineer, at a salary of £250 per annum. Mr. Lobley continues as engineer for capital expenditure in connection with the undertaking, and consulting engineer on revenue account. Two junior assistant engineers are also to be engaged. In future distributing mains required in the district outside the compulsory area are to be arranged for a pressure of 200 volts at consumers' terminals, and the existing mains are to be converted from 100 to 200 volts. Sanction has been obtained to borrow a further £4,000 for electric lighting purposes. The future charge for current will be 5d. per unit (with discount) for all current consumed in the quarter for 150 hours of the maximum payment indicated, and 2½d. net per unit for all current beyond.

Hastings.—The Town Council have taken possession of the electricity supply works, a cheque for £58,000 having been handed to the Hastings Company, leaving only a balance for extensions carried out during the year.

Haulbowline (Cork).—The Admiralty have decided to light the docks, wharves, fitting shops, &c, electrically.

Hobart (Tasmania).—The Hobart Gas Co's. electricity supply station was formally opened at the end of November. The machinery was supplied by Messrs. Siemens Bros. and Co., of London.

Huddersfield.—On Wednesday the Chairman of the Electricity committee (Ald. Calvert) referred to the recent interruptions of the supply of electric current, and said that these were due to the great demand for current which was a heavy tax upon their resources, as the delivery of additional machinery for extensions had been delayed owing to the engineers' strike.

Hurstpierpoint (Sussex).—The Parish Council have notified the promoters of the electric lighting and tramway scheme for Hurst and district that no opposition will be made to the scheme.

Inquest.—On Friday last an inquiry was held into the circumstances attending the death of an engine driver on the City and South London Railway, named Pugh, who was found dead on his engine. The medical man who made the post-mortem examination on the body found no external marks of violence, and the body was well nourished and apparently that of a man who enjoyed good health. There was no disease, the organs being particularly healthy and normal in size and weight. "Having regard, therefore, to all the circumstances of the case," the medical gentleman was of opinion that death was due to shock from electric current, and in this view he was supported by a fellow practitioner who was present at the autopsy. The City and South London Railway Co., however, did not accept this theory, and in order that the body might be examined on their behalf the inquiry was adjourned.

Japan.—A recent report from Japan on the subject of the metal and machinery trades announces that 56 per cent. of the electrical machinery imported into Japan is of British manufacture, against 28 per cent. American, and 12 per cent. German; steam boilers, engines and pumping machinery 80 per cent. British, 16 per cent. American. For 1897 the imports of electrical machinery were valued at £267,000, and boilers, engines and pumping machinery £61,000. Telegraph and other wire imports for 1897 were valued at £25,000, against £22,000 in 1896. About 20 per cent. of the wire imports are British, Germany being the principal source of supply.

Lee (London).—The Blackheath and Greenwich District Electric Light Co. have notified the District Board of Works of their intention to lay mains in a number of streets in the district.

Light Railways.—The Board of Trade have confirmed the order amending the Flamborough and Bridlington Light Railway Order of 1897 and also the order for the construction of the Ventnor Light Railway. The total length of the latter line will be about 1,100 yards. The motive power will be electricity.

Marylebone (London).—The attempts by the Vestry in the last session of Parliament to obtain electric lighting powers are said to have entailed an expenditure of £1,457. 6s. 11d., and £700 has already been spent in preparing the bill now before Parliament.

Newcastle-on-Tyne.—The directors of the Newcastle Electric Supply Co. are considering the question of supplying continuous current for power work throughout their district, and have already entered into a contract to supply the current for driving an electric passenger lift, ventilating fans, &c., in the new Shaftesbury Buildings now in course of erection. They are also to supply current for over 500 incandescent lamps with which the new range of buildings are to be lighted.

Nuneaton.—Representatives from the promoters of the electrical tramway scheme for Nuneaton and Chilvers Coton appeared before the District Council this week to explain their proposals. The overhead trolley system is to be employed. The Council unanimously approved the scheme.

Ogmore and Garw.—The District Council have renewed the contract with the Ogmore Valley Electric Power Supply Co. for the lighting of the district for the ensuing year.

Paddington (London).—On Tuesday the Electric Lighting committee presented a report to the Vestry recommending that counsel's opinion be taken as to the powers of the Metropolitan Electric Supply Co. under existing acts and its provisional order to lay down trunk mains or other electric lines through the parish of Paddington for use in other parishes or districts. Col. Barchard (chairman of the committee) said it had been discovered that the company intended laying down five large cables through their streets, each cable of 10,000 volts capacity, to be brought from Willesden, and the committee considered it a very important question whether the company had power to lay such lines in the district controlled by the Vestry. If the Vestry later on decided to purchase the company's undertaking (so far as it exists in Paddington) this question would become a serious factor in their negotiations. The committee had taken action to prevent the work being proceeded with without referring to the Vestry. It was agreed to take counsel's opinion and to give the committee powers to act as occasion might demand. A communication was read from the Metropolitan Company in reply to a letter from the Vestry, in

Digitized by Google

which the Company deny that any obligations in their provisional order of 1896 remain unfulfilled, and stating that testing stations have been established in accordance with the terms of the order. Sir T. G. Fardell, M.P., said that counsel's opinion should also be taken as to the powers remaining with the Vestry to enforce certain obligations which, he contended, had not been fulfilled in accordance with the order. There were many streets scheduled for the laying of electric mains which had not been laid; whilst other thoroughfares not so scheduled had been opened for the purpose. With regard to testing stations, he contended that what was meant by the order was that testing stations should be established away from the company's premises, so that if a consumer were dissatisfied with the supply of electric current he could go to the station and have the matter tested. Col. Barchard said it was idle to state that the company was not fulfilling its obligations, as the Lighting committee knew that they were. There were 28 miles of streets scheduled in the company's order, and in 24 miles the company's mains had been laid. If the company were compelled to observe the strict letter of their order consumers would not be able to obtain their supply at a cheap rate. At Amberley-road station the company had sufficient power to supply the whole of Paddington, and if the Vestry decided to-morrow to purchase the undertaking for this district this could be effected, as the company could disconnect Amberley-road from their other stations. The matter was left for the committee to deal with.

It was decided that the Vestry should oppose the Baker-Street and Waterloo Railway bill, which provides for the erection of a generating station in the parish. The Central London Railway bill, however, is not to be opposed, nor is the North West London Railway bill so far as Paddington is concerned.

Pokesdown (Bournemouth).—The District Council will oppose the application of the Bournemouth Electric Lighting Co. for a provisional order for the district.

Poplar (London).—The District Board of Works has decided to strenuously oppose the County of London Company's new bill so far as it relates to the Poplar District.

Private Bill Legislation.—In the bill which is being promoted by the Charing Cross, Euston and Hampstead Railway Co. power is sought to extend its authorised system to the Highgate-road station of the Midland Railway Co., and to purchase or lease a portion of the Baker-street and Waterloo Co.'s line. Working agreements are to be entered into with the Midland, London and North-Western, South-Eastern and Baker-street and Waterloo Companies. It is proposed to raise £360,000 additional capital, with borrowing powers for £120,000.

The Great Northern and Strand Railway Bill seeks powers to construct an electric railway in two tunnels from the Great Northern Company's Wood Green Station, via Islington, to the King's Cross station of the Great Northern Company, and thence via Southampton-row and High Holborn to St. Clement Danes in the Strand. The share capital is fixed at £2,400,000 with powers to issue debentures to the extent of £800,000.

The South Staffordshire Tramway Company have deposited a bill to repeal the restrictions upon the sale or transfer of their undertaking and to empower them to lease their system to the British Electric Traction Company. The company also seek power to modify the usual purchase powers by extending the period to 35 years, after which the undertaking can be purchased at the end of any subsequent seven years. The company also wish to increase their borrowing powers from £50,000 to £100,000.

The Sunderland Corporation are seeking powers to acquire and extend the tramways in the district of Southwick, and to introduce electric traction. Power is also sought to extend the electric lighting area so as to include the district.

At the Westminster Palace Hotel last week a meeting was held of representatives of municipal corporations affected by the bills of the General Powers Distributing Co., the South Lancashire and Cheshire Electricity Co., the Lancashire Electric Power Co., and the Midland Electric Power Co.'s provisional order. Ald. Higginbottom, chairman of the Manchester Electric Lighting committee, presided. The resolution passed at the autumn general meeting of the Municipal Association, to the effect that opposition to the General Powers Bill and other similar bills should be organised, was read; and resolutions were unanimously passed that all corporations be requested to urge their members of Parliament to oppose the bills and provisional orders on second reading, and that a statement of the grounds of opposition be issued and circulated.

A meeting of the Council of the Association of Municipal Corporations was also held on the same day, when it was resolved to oppose the bills promoted by the National Telephone Co.

The Corporations of Coventry, Loughborough and Sutton Coldfield, and the District Councils of Rugby, Erdington and Aston Manor, have presented memorials in opposition to the Leicestershire and Warwickshire Electric Supply Co.'s Bill.

Provisional Order Transfers.—The Barnet District Council propose to transfer their provisional order to the North Metropolitan Electrical Power Distribution Co., in return for the company's agreeing to pay the cost of obtaining the order and guaranteeing to give a supply of current by Sept. 1, 1900. The company also engage to provide and erect fourteen 500 to 600-watt enclosed arc lamps in the High-street. The remainder of the streets will be lighted by 146 columns supplied with 16 c.p. incandescents. Powers of purchase are reserved by the Council.

The Weston-super-Mare District Council propose to transfer their order to the Weston-super-Mare and District Electric Supply Co. (Ltd). The Council reserve right of purchase at 10½ years.

Prussia.—In a Foreign Office report received from Berlin in November last, and just published (24 8vo. pages) (!) dealing with the subject of local government in Prussia, attention is called to the terms of the concession granted by the City authorities to the Berlin Tramways Co. By the terms of this concession the city receives 8 per cent. of the gross revenue, and, when the excess of revenue over expenditure permits of a higher rate than 12 per cent. interest being paid on capital, the balance profits are divided equally between the city and the company. The tramways pass through the neighbouring communes of Charlottenburg and Schöneberg, and the local authorities of these districts receive a yearly rental of 3 marks per metre of single line and 6 marks per metre of double line. The company is entitled to pension its officials. The concession expires in 1919. The budget for the city of Berlin for 1898-99 includes £47,000 receipts from the Berlin Electrical Co. for the use of the streets, and £69,000 rentals from the tramways.

Radcliffe.—The District Council have received three proposals for the construction of electric tramways in the district. The Council have already applied for powers to borrow £16,000 for establishing electricity works, and the consulting engineer is of opinion that the current required for working the tramways alone would almost pay the working expenses of the electric lighting station if current were supplied at 1½d. per unit.

Resignation.—Mr. Robert Knight, J.P., Newcastle-on-Tyne, has resigned the position of general secretary to the Boilermakers' and Iron and Steel Shipbuilders' Society, which he has held for 28 years.

St. Luke's (London).—A special committee has been appointed to report upon the desirability or otherwise of the Vestry applying for a provisional order for the municipal supply of electric current in the parish, and to obtain the necessary technical and professional assistance. Twelve months ago the Vestry rejected a similar proposition. Mr. A. Pond, who sponsored a motion to the above effect at the last meeting of the Vestry, pointed out that Shoreditch, Islington, Hampstead and other parishes in the north of London were engaged successfully in supplying electric current. Messrs. Howes, Pond, Standring, Rumball, Miller, Elven, Basterfield and Whitehead form the committee.

Consent to the application of the Smithfield Markets Electric Supply Co. for a provisional order for the St. Luke's district has been refused.

St. Pancras (London).—A report of the Electricity and Public Lighting committee to the Vestry, on Wednesday, stated that by the aid of temporary plant at the Regent's Park supply station the Christmas extra demand for current was satisfactorily met. The new station is progressing satisfactorily but for occasional delays through the weather. Two out of the four boilers have been delivered, and one has already been in use. The committee further reported the receipt of a quotation from the Brockie-Pell Arc Lamp (Limited) for the supply of 50 Brockie-Pell arc lamps, at £8. 15s. each, and "in view of the satisfactory running of the old lamps during the past seven years" it was decided, on the recommendation of the committee, to accept the quotation.

Salford.—Mr. Haworth, in presenting the Electricity committee's report to the Town Council, on Wednesday, said that when the new committee was formed the electricity undertaking was working at a loss of £4,000 per annum. In the first twelve months they increased the average consumption of current per lamp from 5·2 to 14 units per annum, and the revenue went up from 2s. 9d. to 4s. 2d. per lamp. In 1897 they sold 110,000 units, and last year 324,000 units, and but for a serious accident the deficit for the year ending March would not be more than £300. Owing to the increasing demand for current, and also in view of the prospect of the adoption of electric traction, he moved that Messrs. Lacey, Clirehugh and Sillar be appointed consulting engineers for a term of three years, at a salary of £500 per annum. A discussion ensued, but the question was adjourned until Wednesday next.

Saltburn.—Messrs. Cox-Walkers, Darlington, are putting down electric light plant for supplying current for private lighting in this district.

Shoreditch (London).—At Tuesday's meeting of the Vestry, Mr. H. E. Kershaw submitted the report of the Lighting committee giving some figures prepared by the chief electrical engineer concerning the growth in the demand for current. The units sold in the quarter to Sept. 30, 1897, were 57,452, to September, 1898, 203,892, and in December to 313,558 units. These figures, the committee urged, justified the expenditure in connection with the

Digitized by Google

projected new generating station. The committee have appointed a sub-committee to consider the question of available sites for the new station. On the recommendation of the committee, it was resolved to order new cables from the British Insulated Wire Co. at a cost of £2,750.

Southampton.—At the meeting of the County Council, last week, the Tramways committee reported that they were now in a position to present a complete electric tramway scheme. A report has been prepared by the consulting engineers, Messrs. Kincaid, Waller and Manville, who approve the overhead trolley system as already adopted by the Council, and recommend the doubling of all lines where possible; also the retention of double-deck cars throughout the system, the lowering of the roadway through the Bargate, the taking of a protected trolley wire under the gate, the electrical equipment of the entire system, and the provision of a stock of 20 motor cars with running sheds. The estimated cost of the entire scheme complete is £63,722. The above estimate includes the cost of providing equipment for three additional miles of line and six miles of new tramroad. The whole of the committee's recommendations were adopted.

Southport.—Electric current is to be supplied for motive power at 7d. per unit for the first hour and 2d. after.

Tariff Changes.—Cylinders, rods, sticks, pencils, plaques, sheets or blocks, &c., of agglomerated carbon for use in electrical apparatus are now subject to a duty of 5 per cent. *ad valorem* on importation into *Belgium*. Brass fittings for electric lamps are assessed for duty at 75 lire per quintal on importation into *Italy*.

Uitenhage (South Africa).—The Town Council are anxious to establish electricity supply works, and Sir James Sivewright has been requested to name a consulting engineer for drawing up a scheme.

United States Patent Law.—Messrs. Fairfax and Wetter write:—An important decision affecting many English inventors was given by the Commissioner of Patents, at Washington, on Dec. 20. According to Sec. 4,887 of the U.S. Statute which became operative on Jan. 1, 1898, an inventor who had first applied for a patent in a foreign country would not be debarred from receiving a patent for the invention in the United States by reason of its first having been patented abroad, unless the application for said foreign patent was filed more than seven months prior to the filing of the application in the United States. Now, as the majority of inventors in England file a provisional specification, and obtain provisional protection before they file a complete specification, on the base of which the patent is granted, a few experts had arrived at the conclusion that, in the case of the English patent, the date of application referred to in the said Statute would be the date of filing the complete specification. On Dec. 20 the question came before the Commissioner of Patents, who held that the date of application for an English patent is the date on which the original application was filed, even if it has been accompanied only by a provisional specification, the reason given being that, according to English law, provisional protection is not analogous to a caveat. And the patent, when granted, is dated as of the day of application, instead of bearing the date of the actual grant or issue, as is the case in the United States and some other countries. English inventors must therefore be careful to apply for a United States patent in good time, if they wish to obtain protection for their invention in the United States.

Wellingborough.—The electrical engineer to the Leyton District Council (Mr. H. Collings Bishop) has paid a visit to this town, and will report upon the question of the erection of electric light and refuse destructor works.

Whitechapel (London).—The London County Council is be asked to grant a loan of £25,000 to the District Board of Works to defray the cost of the purchase of land in Osborne-street, George-yard and Wentworth-street for an electricity supply station, and the Electrical Committee recommend, and the Board approve, the application to the Council for a further loan of £60,500 for the erection and equipment of the station. The erection of a new dust destructor, at a cost not exceeding £15,000, has also been agreed to.

Workhouse Lighting.—The Islington (London) Guardians have instructed Mr. J. S. Enright to prepare a report on the electric lighting of the workhouse at a fee of ten guineas. There were 34 applications for the appointment.

Dinners and Presentations.—Last week a farewell dinner was given at Dover to Mr. A. A. Whitlock, resident engineer at the Dover electricity works, on the occasion of his leaving Dover to take the position of engineer at the County of London and Brush Provincial Company's station, at Wandsworth (London). Mr. Whitlock has also been the recipient of a presentation from the Directors of the Dover Electricity Supply Company, in recognition of his services.

The annual dinner of the staff of the Langdon-Davies Electric Motor Co. was held on Saturday at the Bridge House Hotel, London Bridge. Mr. A. Soames (managing director) occupied the chair, supported by Mr. W. Langdon-Davies (engineer), and Mr. W. F. Davidson (works manager). About 50 sat down.

Electro-Harmonic Society.—A smoking concert will be given at the St. James's Hall Restaurant, Regent-street, London, on Friday evening, Jan. 27, at eight o'clock. A lengthy and attractive programme will be provided.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by Mr. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom all information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete Specifications. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

December 31, 1898.

27,593. THE BRITISH THOMSON-HOUSTON CO. (LIMITED). London. Improvements in systems of train control for electrically-propelled vehicles. (F. E. Case. United States.)*

27,599. C. DUBEY. Liverpool. Improvements in electro-hydraulic brakes for railway vehicles and other purposes.*

27,613. C. HOWARD. London. Improvements in electric fuse holders.*

27,614. J. R. HATMAKER. London. Electrolytic or battery liquid.

27,636. A. M. ARTER. London. Improvements in electric arc lamps.

January 2, 1899.

2. J. S. HIGHFIELD. St. Helens. Improvements in apparatus for connecting electric mains.

8. W. H. VAUGHAN and T. FOSTER. Manchester. An improved electric reversing switch with liquid resistance.

20. T. E. WEAVER. Wolverhampton. A new or improved electric heater.

44. W. H. HARFIELD. London. Improvements in apparatus for electrically controlling engines, electro-motors and other machinery.

January 3, 1899.

96. J. M. ANDERSEN and A. ANDERSON. London. Improvements in supports for electric conductors.*

COMPANIES' MEETINGS AND REPORTS.

Eastern Telegraph Co. (Limited).

The fifty-third half-yearly ordinary general meeting of this Company was held yesterday (Thursday) at Winchester House, Old Broad-street, London, under the presidency of the Marquis of TWEEDDALE, K.T.

The SECRETARY (Mr. George Draper) having read the notice calling the meeting,

The CHAIRMAN said that he would as usual draw their attention to the more important features of the business of the past half-year. The gross revenue for the six months to September last amounted to £444,011, or an increase of £284 over that of the corresponding period of 1897. During the September half of 1897 they derived extra traffic from Crete owing to the disturbed condition of that island, but this traffic had since resumed its normal state. There were other fluctuations in various classes of traffic, but in no case were they so important as to call for special attention. The total ordinary expenses for the half-year to September last were £121,376, showing an increase over those of the corresponding period of 1897 of £12,133. This increase comprised in the present half-year's figures several items of an exceptional character which did not appear in the corresponding period of the previous year, and which would not recur. The increase in the ordinary expenses had really amounted to £5,503, and the nature of this increase was fully explained at the last meeting. He might remark that their expenses had a tendency to grow in a greater ratio than the revenue. A Company such as theirs existed for the benefit of the public as well as for that of its shareholders, and they had accordingly spent, and would continue to spend, large sums in improving the efficiency of their service; and from time to time they had also made extensive, and they hoped to make still further, reductions in their rates. For the reasons given at the last general meeting it was not possible to compare several items in abstract "A" (general expenses in London) and abstract "B" (working expenses at stations). The expenses attending repairs and renewals of cables during the half-year had amounted to £41,716, or an increase of £10,079. In comparing the actual ships' expenses they found a decrease of £2,571. The increase in the total was due to the large amount of cable used on repairs, the Malta-Alexandria No: 2 cable alone requiring no less than 222 knots. The amount received from Governments and other companies for repairs to their cables during the half-year amounted to £7,172 less than in the corresponding period of last year. The net result of the working during the half-year might be briefly summed up as follows:—The gross revenue amounted, as he had already pointed out, to practically the same figure as last year, but the working expenses, the expenses in connection with repairs to cables, and the charges against revenue in respect of dividend on the additional amount of Preference stock were all heavier, so that they carried £5,000 less to the general reserve fund, £15,000 less to the minor reserves, and £6,457 less balance forward to next half-year. Notwithstanding these reductions, however, he thought, after the explanations he had given, that they would consider the result on the whole satisfactory. He was glad to be able to add that the receipts so far as they had gone in the current half-year had been fully maintained. The Preference stock certificates had practically been all issued, and the greater portion (about 8,000) of the Ordinary certificates had been issued, but there were still about 800 shareholders who had not sent in their old Ordinary share certificates to be exchanged for Ordinary stock certificates. If any shareholder should be present who had not done so, they would feel obliged by his giving the matter attention without delay. With reference to the additional cables between Porthcurnow and Gibraltar, Malta and Alexandria, the first section had been laid; and since the report was issued the remaining sections between Malta and Gibraltar and Malta and Alexandria had also been successfully completed, and they would shortly be opened for traffic. The cost of these cables would be partly taken from the general reserve fund. They had under consideration tenders for a new cable repairing steamer to replace the "John Pender," which had been sold. The amount received for the old ship would be credited to the maintenance ships' fund, and the cost of the new vessel would be taken out of that fund. He concluded by moving the adoption of the report and accounts.

The VICE-CHAIRMAN and MANAGING DIRECTOR (Mr. J. Denison-Pender) seconded the motion, which was carried unanimously.

Resolutions were afterwards passed re-electing the retiring Directors—Mr. C. S. Colvin, C.S.I., and Sir Henry C. Fischer, C.M.G.—and the auditors, Messrs. Deloitte, Dever, Griffiths and Co., and Messrs. Welton, Jones, and Co.

An extraordinary general meeting was held subsequently, to consider the following resolutions:—

"*1. That Article 29 of the Company's Articles of Association be altered by striking out the amount £10, and inserting in lieu thereof £1.*"

"*2. That the Directors of the Company be and they are hereby authorised (in accordance with Section 6 of the Eastern Telegraph Company's Act, 1898) from time to time to create and issue Debentures or Debenture stock charged on the revenue and undertaking of the Company, so, however, that the total amount of Debentures or Debenture stock for the time being created and issued shall not exceed one-third of the total amount of the capital in Ordinary and Preference stock and shares for the time being created and issued and paid up, and so that all Debentures or Debenture stock created and issued by virtue of this section shall rank* pari passu *with the existing 4 per centum Debenture stock of the Company.*"

The CHAIRMAN, referring to the resolutions, explained the necessity for altering the Articles of Association and the advisability of granting powers to the Directors to issue from time to time the balance of the mortgage debenture stock.

On the motion of the CHAIRMAN, seconded by the VICE-CHAIRMAN, the resolutions were put to the meeting separately, and were carried unanimously.

Mr. PARRITT afterwards proposed a vote of thanks to the Chairman, Directors, the Secretary, and Staff, and having warmly recognised their services to the Company, congratulated the Chairman on the honour which had been conferred upon him by Her Majesty.

Mr. G. B. SYMES seconded the motion, which was carried unanimously.

The CHAIRMAN acknowledged the vote, and the proceedings then terminated.

[*We shall publish a full report of these meetings in our next issue.*]

Potteries Electric Traction Co. (Limited).

An extraordinary general meeting of this Company was held on Monday to consider a resolution to amend the articles of association. The chair was taken by Mr. EMILE GARCKE.

The SECRETARY (Mr. J. G. B. Elliot) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, this is an extraordinary general meeting called for the purpose of altering the articles of association as required by the Stock Exchange, and it is necessary for us to carry them out before we can proceed with the application for a quotation of the shares. I am glad to have the opportunity of treating this meeting as if it were the statutory meeting, and thus giving any shareholder the opportunity of asking questions as if we were holding the statutory meeting. My first duty, however, is to propose the resolution, of which notice has been given and which the Secretary has read, and before sitting down I will mention a few matters for your general information. The Company was registered on June 28, and the statutory meeting was called in October and adjourned to November, when it was held. Then we issued a prospectus, and the whole of the share capital was subscribed, namely, 20,000 Preference shares and 20,000 Ordinary shares, which were allotted. The 20,000 Ordinary shares included 6,666 which were issued to the British Electric Traction Co. as fully paid in part payment of the purchase price. You may, perhaps, have heard that the shares were not very fully subscribed by the outside public, but the British Electric Traction Co. and the Electric and General Investment Co., took up the whole of the capital which was not so subscribed. After referring to the appointment of Mr. C. S. Drummond to a seat at the Board, the Chairman continued: You are aware that the undertaking practically consists of three separate tramways. The first is the North Staffordshire Tramways, which we have taken over; the second is the tramways extensions which were authorised under a Provisional Order of August, 1896; and the third comprises the lines authorised under the Light Railways Order, which was confirmed by the Board of Trade in December, 1897. With respect to the North Staffordshire Tramways, they have been in course of conversion to electric tramways for some months; we are very hopeful that they will be opened for traffic by electricity in the course of a few weeks now, and we believe that this will have a very marked effect on the revenue of the undertaking. There have been many delays. I cannot, at this meeting, precisely say to whose fault the delays are attributable. In undertakings of this kind we have various difficulties to meet with. With reference to the tramways extensions—which I call the second undertaking—they have been under construction for some time; the electrical equipment is also well in hand now, and we hope to make rapid progress towards completing those lines. With respect to the light railways, they are also under construction, but we are not in so great a hurry to complete that work, as we have ample time to do so under the Light Railways Order. Still, it is very desirable to complete them as soon as possible, because, until the whole of the lines are completed and working by electricity, we shall not derive the fullest advantage from the system. For the Tramways Extension Order—what I call our second undertaking—we had not a very long time given to us for completion, and the time allowed by the Board of Trade expires on February 7th next; but we have applied to that department for a further extension of time, and I am glad to say that, although at first there was some opposition from the local authorities to the further extension, they have now approved of the proposal. They will, therefore, support the application to the Board of Trade for an extension of time for six months, but I hope that we shall not want the whole of that period. I think I have now touched upon all the points that it was necessary for me to inform you upon. After the resolution for which this meeting has been called has been passed, I shall be happy to answer any question.

Mr. J. S. RAWORTH seconded the motion, which was carried unanimously.

A vote of thanks to the Chairman terminated the proceedings.

London Electric Omnibus Co. (Limited).

The third general meeting of this Company was held on Saturday last Major S. FLOOD PAGE presiding.

The CHAIRMAN reminded the shareholders that about a year ago a committee was appointed, and that, as the result of their investigations, the Directors received a mandate to go on and see if anything better could be done. During the period which had since elapsed they had been endeavouring to ascertain exactly the whole of the conditions necessary for the working of electric traction, especially in reference to accumulators for omnibuses. He believed they had got a good asset in the Sola accumulator, but they had not been able to take any steps for dealing with it, owing to rival claims which were set up. The matter had been referred to arbitration, and he understood that a decision had now been given. The

Digitized by Google

Board long ago came to the conclusion that this Company could not manufacture omnibuses, even if they possessed the capital, and it, therefore, became necessary to obtain the services of people with considerable electrical knowledge who would be able to deal with the problems involved. With this object they had assisted in establishing a Company for the manufacture of omnibuses at Wolverhampton—the Electric Street Car Manufacturing Co.—of which he was the Chairman. He had been told that an electric omnibus had, within the last two weeks, been running about the streets of Berlin. With that exception there was not a single electric omnibus in Europe running along the streets without rails. This Company had not made any progress except of a theoretical character. They possessed three omnibuses which had been driven about the streets of London three or four hours a day successfully, but they had not yet been able to run their 26-passenger omnibus continuously throughout the day, and that was what they must do to compete with the horse-drawn omnibus. The Board had learned that there was a great deal more to be done than anybody thought at the time the Company was started. He stated in conclusion that Mr. Flack and Mr. Fox had resigned their seats on the Board.

Lieut.-Col. T. T. TURNBULL (Managing Director) remarked that when he came to look into things at the works he found it necessary to put a stop to a great deal of expenditure there. As to the Company's 26-passenger omnibus, it was impossible to find a man competent to drive it about the streets of London in its present shape. It was altogether too heavy a vehicle. He believed the Sola accumulator was a good one, but it required to be further developed. The mistake which this Company had made was that they had started with omnibuses of a weight which was beyond the power of the present accumulators to work. At Wolverhampton a lighter omnibus had been manufactured, which was, in many respects, a serviceable vehicle. He had driven it quite easily, but it contained certain defects which made it impossible for him to recommend its immediate purchase by this Company. He hoped the existing defects would be remedied before long. It was for the shareholders to say if they considered it worth their while to join together and find a little more money to carry on the Company. He thought that it would be, as it was his opinion that they had now reached that stage when all money put into the Company might be regarded as a good investment.

Mr. W. M. HAWKINS asked what was the price of the new omnibuses which had been referred to?

The CHAIRMAN replied that the price was about £500 each fully equipped.

The CHAIRMAN, referring to the agreement which was to be submitted to the shareholders for terminating the arrangement between Mr. M. Radcliffe Ward (one of the vendors and the engineer) and the Company, said that the conditions of that gentleman's engagement were of an onerous character. He not only received £1,000 per annum, but had full control and authority over the technical and engineering staff of the Company. Designs for omnibuses could not be accepted by the Board except with the consent of Mr. Ward. The accounts kept by that gentleman had not been properly kept, and the Directors had been obliged to accept his word for large sums. If the shareholders decided on the liquidation of the Company he (the Chairman) should propose that it should be wound up under the supervision of the Court so that everything might be disclosed to the shareholders.

Mr. WARD said that he challenged the fullest investigation into all the expenditure with which he had been concerned. Although nominally a vendor, he was not one actually, and had only received £200 in cash. Speaking of the Company's omnibuses, for the manufacture of which he was responsible, he said that their cost would bear favourable comparison with that of any first vehicles of a similar kind.

After further discussion the report and accounts were adopted; and the shareholders indicated by a show of hands, that they were favourable to the reconstruction of the Company, whereupon the Chairman stated that the Board would in a short time submit a scheme for that purpose.

At an extraordinary general meeting the provisional agreement, dated November 16th last, for severing Mr. Ward's connection with the Company was unanimously approved.

The trouble between the directors and Mr. Radcliffe Ward indicated in the above report has led to the publication, by the latter gentleman, of a circular, setting out his grievances against the board. In this circular—which, by-the-way, is accompanied by illustrations of an electric omnibus which is described (in the circular) as one of the most successful automobiles yet produced, but which bears indication of French origin—the directors are charged with issuing a report of a shamefully meagre character, and he asks for more daylight to be given to the shareholders on the subject of the prospectus of the company generally, and as to the scheme of reconstruction. The circular has little interest for anyone not a shareholder in the company, but, as is usually the case in documents of this nature, a good deal of forcible language is used—some of it in large type.

Amazon Telegraph Co. (Limited).

The report of the Directors of this company for the year ending June 30 last, states that the revenue, including £5,137. 16s. 4d. brought forward last year, amounts to £29,466. 8s. 10d., and the working expenses to £18,494. 10s. 3d., leaving, after deducting £8,870 for debenture interest and sinking fund, £2,081. 18s. 7d. to be carried forward. This shows an increase of £4,148. 14s. 2d. over the year to June 30, 1897, notwithstanding that several sections of the cable were interrupted. When the through line works regularly a steady and increasing traffic is at once developed. Owing to the unusually heavy flood season, the system has again, unfortunately, been subjected to interruption, and in parts where safety was reasonably expected, the banks in places were washed away, but every effort is being made to cope with these difficulties. The Directors are substituting indiarubber for guttapercha core, as the former is less liable to damage from heat; and they have recently sent out 100 miles of indiarubber cable, which is now being laid in some of the localities where interruptions have occurred. It is also proposed to try aerial lines where exceptional difficulties have arisen, and by this means bridge over such dangerous places. In order to carry out these and other improvements, further financial assistance is required. The Directors have, therefore, arranged for advances to be made from time, as may be necessary, against a deposit of the companys Debentures, and will ask the shareholders' sanction for the creation and issue of the balance of £75,000 unissued Debentures, in order that these may be available as security for such advances as may be required.

Yorkshire House-to-House Electricity Co. (Limited).

The following report of the Directors of this Company is issued for the year to Dec. 31 last:—

The Leeds Corporation, in exercise of the powers conferred by the Company's Provisional Order, gave notice on Aug. 4 last, requring the Company to sell its undertaking. As the result of negotiations, it was agreed that the sale should take effect, as regarded capital expenditure, on Aug. 31, 1898, and as regarded revenue on Sept. 30, 1898, and that agreement was approved at a meeting of the Company, held on Nov. 21 last. The capital expenditure to Aug. 31, 1898, after deducting depreciation, was found to be £217,420. 10s. 4d., and the purchase price is therefore to be paid, in accordance with the provisions of the Provisional Order, by the issue of £217,420 of Leeds Corporation Five per Cent. Stock, redeemable only by agreement between the Corporation and the holders of the stock for the time being. The amount of capital assets included in the accounts is merely the nominal value of the stock, the market value of which cannot at present be accurately estimated. The transfer of the undertaking was completed on Dec. 15 last. The Corporation have retained the services of the whole of the Company's staff.

The shareholders will be invited to pass a resolution for the liquidation of the Company, and the Directors will submit the name of Mr. Grosvenor Talbot (chairman of the Company) as liquidator, and the names of the other members of the Board as an advisory committee. Mr. John Gordon, the Company's auditor, will be appointed to audit the liquidator's accounts.

The supply of electricity by the Company on its own account having ceased on Sept. 30 last, the revenue account now submitted shows the result of only nine months' trading, and excludes the most profitable quarter of the year. The profit available for dividend, including £1,329. 2s. 5d. brought forward, and after providing £2,612. 6s. 8d. for depreciation, on the scale demanded by the Board of Trade auditor, is £10,740. 5s. 10d., which the Directors propose shall be appropriated as follows:—

Interim dividend at the rate of 5 per cent. per annum on the Ordinary shares for the half-year to June 30, 1898	£3,671	6	5
Dividend on amount called and paid up on same shares (which, with interim dividend, equals the rate of 6¾ per centum per annum for year to Dec. 31)	6,981	9	8
Balance forward	87	9	9
	£10,740	5	10

The number of lamps connected to the Company's mains increased during the nine months ending Sept. 30, 1898, from 49,150 to 65,328 (35 watt lamps).

The Directors express their hearty appreciation of the work done by the staff during the existence of the Company, more especially by Mr. Green, the secretary, and Mr. Harold Dickinson, the engineer, who have held their positions since the commencement, and whose ability and disinterested services have been of the greatest value in developing the undertaking. The Directors also recognise the conspicuous care and skill exercised by Mr. Robert Hammond, consulting engineer, in designing and superintending the construction of the works, as well as his valuable efforts in establishing the Company and obtaining the Provisional Order for supply of electricity in Leeds.

NEW COMPANIES, STATUTORY RETURNS, &c.

KALGOORLIE POWER SYNDICATE (LIMITED).—This company was registered on Jan. 10, with a capital of £10,000, in £1 shares, to promote a company to provide and apply electric power for mining and other purposes. The first subscribers (each with one share) are:—M. E. Williams, G. Neville, J. B. Sealy, and J. Doyle, E. Pope, G. Baker and C. E. Mozley.

SWANSEA MOTOR OMNIBUS CO. (LIMITED).—This company was registered on Jan. 10, with a capital of £20,000, in £10 shares, to construct, maintain and work omnibuses, vans and other vehicles, by electricity, steam, oil, or other motive power. The first Directors are:—J. C. Morris, J. Williams, O. Walters, T. P. Thomas and E. H. Leeder.

STOCK EXCHANGE NOTICES.—The Stock Exchange committee has appointed the 26th inst. a special settling day for 100,000 £1 Ordinary shares (10s. paid, and numbered 1,201 to 101,200) of the Blackheath and Greenwich District Electric Light Co. (Limited), which the Committee has also ordered to be quoted in the Official List, as well as the further issue of 5,403 fully paid £5 Ordinary shares (Nos. 484,598 to 490,000) of the National Telephone Co. (Limited).

CITY NOTES.

MEMORANDA.—Bank rate 4 per cent. (since Oct. 13, 1898). Price of silver 27 9/16d. per oz. (Jan. 19). Consols (2¾ per cent.) 111¼—111⅜ for money, 111 5/16—111 7/16 for account; 2½ per cent. 103¾—104¼ (Jan. 19). Stock Exchange Settling Days: Consols, Feb. 1; Stocks and Shares Continuation Days, Jan. 25 and Feb. 8; Ticket Days, Jan. 26 and Feb. 9; Pay Days, Jan. 27 and Feb. 10; Mining Share Carry over Days, Jan. 24 and Feb. 7.

BRITISH ELECTRIC TRACTION CO. (LIMITED).—The Electric and General Investment Co. have this week invited applications for 20,000 Six Per Cent. Cumulative Preference shares of £10 each in the British Electric Traction Co. (Limited) at £12 per share. The additional capital is required for the development of a large number of electric light, tramway and railway undertakings in which the British Company are interested, either as owners or lessees. Applications from registered holders of shares in the British Electric Traction Co. were preferentially considered. The list closed yesterday (Thursday) for both town and country.

BRITISH INSULATED WIRE CO. (LIMITED).—The Preference dividend for the half-year ending Dec. last (3s. per share, less tax) has been declared.

CITY AND SOUTH LONDON RAILWAY CO.—The accounts of this company show a balance (after providing for debenture interest and the full dividend on the Five per Cent. Preference shares) sufficient to allow payment of a dividend on the Consolidated Ordinary stock at the rate of 2 per cent. per annum, carrying forward £1,419 to the new account. The distribution for the corresponding period last year was at the rate of 1¾ per cent. per annum, the balance carried forward being £1,510. 14s.

COUNTY OF LONDON AND BRUSH PROVINCIAL ELECTRIC LIGHT CO. (LIMITED).—An extraordinary meeting of the shareholders was held on Monday to consider the bill for compulsory powers promoted by the company. The meeting was called to comply with Parliamentary standing orders. Lord Rathmore said the main object of the bill was to enable the company to obtain compulsory powers for acquiring sites for generating stations and rights of way for connecting its various districts.

DUBLIN UNITED TRAMWAYS CO. (LIMITED).—Subject to final audit, the Directors of this company have declared a dividend of 6 per cent. per annum on the Preference shares and 5 per cent., free of tax, on the Ordinary shares for the half-year to Dec. 31. Including amount brought forward from the June half-year, the surplus profits amount to about £9,000.

EASTERN EXTENSION, AUSTRALASIA & CHINA TELEGRAPH CO. (LTD.)—The interest on this company's 4 per Cent. Mortgage Debenture Stock for the half year ended 31st inst., will be paid by warrant on Feb. 1. The stock register will be closed from 27th to 31st inst. inclusive.

ELECTRIC CONSTRUCTION CO. (LIMITED).—The transfer books of the Ordinary shares of this company are closed from 18th to 31st inst. inclusive, for the payment of the second half of the dividend of 6 per cent. per annum declared on July 21.

GLOBE TELEGRAPH AND TRUST CO. (LIMITED).—The financial papers announce that this company has declared a quarterly interim dividend of 3s. per share on the Preference shares and 1s. 9d. per share on the Ordinary shares.

HAMPSTEAD ELECTRIC SUPPLY CO. (LIMITED).—The Directors of this company notify the payment of the dividend on the Five per Cent. Cumulative Preference shares for the half-year ended Dec. 31.

HASTINGS AND ST. LEONARDS-ON-SEA ELECTRIC LIGHT CO. (LIMITED).—At a meeting of this company, on Thursday last, it was decided to wind up the company voluntarily, consequent upon the acquisition of their undertaking by the Corporation, and Mr. James Woodhams, auctioneer, Havelock-road, Hastings, was appointed liquidator.

WESTERN AND BRAZILIAN TELEGRAPH CO. (LIMITED).—Notice is given that Debentures, series A, to the amount of £8,900, and series B, to the amount of £10,500, will be drawn for payment at par, at the offices of the company, on Wednesday next.

WEST INDIA AND PANAMA TELEGRAPH CO. (LIMITED).—The estimated amount of the traffic receipts of this company for the half month ended Jan. 15 is £1,891, against £1,997 in the corresponding period of 1898.

NOTES.

IT may be hoped that the new Secretary to the Post Office will not be over much frightened by the *Daily Telegraph's* description of the Department to which he has been reluctantly transferred. Not only is the telegraph system of this country "the worst in the world," but the officials, both postal and telegraphic, are fossilised "in adamantine rules and regulations through which no glimmer of reasonable argument or common sense can penetrate." His task would be indeed stupendous if such statements were true; but seeing that the pages of this self-same journal only a few days before had overflowed with praises of the two most exalted of these official fossils on their retirement from the service, Mr. MURRAY need not take the *D. T.* too seriously. "A Day and Night Telegraph Service" may or may not be a good thing, according as it is or is not called for by local requirements; but that certain towns would like to have it and are not willing to pay for it, is no excuse for statements which are not only extravagant but altogether erroneous.

AFTER all has been said, the question is not wholly one of expense. It is to be noted that while every other kind of business has been tending latterly to shorten hours, and to lighten duty in the evenings, the tendency in the Post Office has been to prolong the hours for all classes of business further and further into the night-time; and this in deference to some real or fancied demand on the part of the public. No doubt further concessions will be made if there is a genuine call for them. But, reading between the lines, and from certain hints let fall here and there, we suspect that the ultimate object of this agitation is to obtain a considerable extension of hours on Sundays; and we doubt whether this is an alteration which the general public have the least desire to encourage. Lastly, as the Telegraph Service does not pay its way, the appeal to the tremendous profits earned by the Postal Service is not likely to have much weight with a Post Office Secretary.

THERE is no doubt that for telegraphic work the underground cable is in every way preferable to the overhead line, except so far as cost is concerned. The use of loose paper as a dielectric diminishes the electrostatic capacity which might otherwise impede long-distance high-speed signalling, and by giving access to the cable at a sufficient number of testing points, its inspection and the locating of faults are rendered almost as easy as on an overhead line. As will be gathered from the article on the London-Birmingham cable in another column, however, the cost of laying, apart from the price of the cable itself, must be considerably more than the sum spent on the erection of an equivalent number of overhead lines; and this may stand in the way of the general adoption of underground work for extensions. The cost, we think, could be considerably diminished by utilising an armoured cable laid directly in the ground, at all events in the country roads which form by far the greater part of the route of a long-distance cable. Such a line would still be less liable to disturbance than the existing overhead wires, and, in the rare event of a fault occurring, with the large engineering staff at the disposal of the telegraph department, the localisation and removal of the defect should take no longer than the withdrawal and replacement of a section of cable placed in iron pipe. One fact is certain, namely, that, except for short distances, paper is the insulation *par excellence* or underground telegraph cables, and it is only necessary to find a suitable waterproof, mechanically strong, and a sufficiently light protective covering, for this class of insulation to supersede gutta percha in submarine work as well as on land.

So far as telephony is concerned, paper or "air space" cable is now recognised as the most suitable for underground work, and in towns underground cables are given the preference over aërial lines. Whether in this case also underground cables will prove best for long distance work has still to be determined. In telephone work capacity plays a still more important part than in the sister service, and the majority of cables in use hitherto have capacities, although low, yet considerably in excess of those of overhead lines. It must be remembered, however, that by increasing the distances between the wires in the cable a great diminution

Digitized by Google

of the capacity is possible, the only real deterrent being the increased diameter of the cable and consequent increased cost of the sheathing, and, in drawn-in systems, of the pipe-line.

THE time is now ripe for an investigation, confirmed by an actual experiment under practical working conditions, to determine the relative maximum permissible values of line resistance and capacity for distinct speech to be transmissible with modern telephonic apparatus. In cables with paper and air insulation, as now constructed, both the inductance and leakance are practically zero, the former being necessary to ensure immunity from external disturbance. When this has been determined, a second problem would be whether it would pay to use lower insulations at the expense of slightly higher capacities, by not carrying so far the drying process in the manufacture of the cable. If the efficiency of the cable for speech transmission were increased by this means, an increase in the conductor-resistance would be permissible, which would, again, lessen the cost. When numerical solutions are given to these problems it will be possible to compare exactly the merits and demerits, from an economical point of view, of overhead and underground long-distance telephone lines, and we shall also be clearer in regard to the distance to which submarine telephony may be economically extended.

CARLYLE once made sarcastic allusion to "the combined folly of a number of fools" being often mistaken for wisdom. It is the special brand of wisdom too frequently found among juries. On the 10th inst., as reported in our last issue, an engine driver was found dead on one of the electric locomotives of the City and South London Railway, and at the inquest a Dr. MORRIS attributed death to electric shock, as "there was nothing else to account for it." Mr. MCMAHON, the Company's chief engineer, gave evidence as to the physical impossibility of electric shock in the position in which the switches, &c., were found; while three medical men, Drs. LESLIE, HENRY and BELL, having made an autopsy, agreed that death was due to ordinary heart failure, that the condition of the heart would render the deceased liable to fainting attacks, and that there was no burning nor charring of the skin. The coroner, in summing up, pointed to the positive evidence that it was impossible for the deceased to receive an electric shock; yet a presumably intelligent body of twelve good men and true found that "death was due to syncope following an electric shock!"

MR. A. C. BROWN'S contribution to the recent discussion on the three Papers on induction telegraphy at the Institution of Electrical Engineers was not fully appreciated by his audience, chiefly, it must be confessed, owing to his being somewhat imperfectly heard. As will be seen by his letter in another column, he had something of considerable importance to say, although it related rather to earth-conduction than to induction telegraphy. The most sensitive current detectors are those responding to interrupted or alternating currents; but, on the other hand, Mr. BROWN had found experimentally that signals formed by short but continuous currents are transmitted by earth-conduction with more efficiency than are rapidly varying ones. In order to use these continuous-current signals in conjunction with a telephone or a relay requiring a high frequency, he interrupts the received instead of the transmitted current. This principle, it would appear, is the basis of his methods of telegraphing through bare wires and broken cables, and we shall be glad to hear that his efforts in this direction have been crowned with success.

Cable Interruption.—	Date of Interruption.
Para—Maranham	Nov. 15, 1898

Electrical Engineers (R.E.) Volunteers.—The first smoking concert of the corps of Electrical Engineers (R.E.) Volunteers will be held this evening at the Holborn Restaurant, London, at eight o'clock.

Royal Society.—Among the Papers down for reading yesterday was one by Mr. S. W. J. Smith, on "The Nature of Electro-Capillary Phenomena. I.—Their Relation to the Potential Differences between Solutions."

Personal.—In appreciation of his services as one of the two British representatives on the Superior Jury of the Brussels Exhibition, the King of the Belgians has appointed Mr. W. H. Massey an Officier de l'Ordre de Léopold.

The Rocent Fatal Accident at Southampton.—We have received a copy of Major Cardew's report of the inquiry he made into the recent fatal accident at Southampton. Owing to great pressure on our space we are unable to reprint it this week; but the report is of considerable importance, and we reserve our comments until its publication in full in our next issue.

A New Accumulator Switch.—In connection with our description of Messrs. Erlacher and Besso's accumulator switch in our last issue, Messrs. Verity's send us a copy of patent No. 8,048 of 1897, granted to Messrs. L. W. Heath and J. H. Field, which they state it is their opinion is infringed by Messrs. Erlacher and Besso's switch. They assert that the patent in question bears a date two months earlier than the Swiss inventors' patent. Messrs. Veritys add that they have the sole right to manufacture switches under the Heath and Field patent.

"The Archives of the Röntgen Ray."—We note that the November issue of this official journal of the Röntgen Society is under the joint editorship of Mr. Thomas Mcore, F.R.C.S., and Mr. Ernest Payne, M.A., assisted by an editorial committee. Mr. Sydney Rowland, who was the originator of the publication, and one of the first to bring the new photography prominently before the medical profession, has accepted a post on the staff of the *British Medical Journal*. Dr. W. S. Hedley also has vacated the editorial chair, but the services of both these individuals will be available on the editorial committee.

Sweating in the Post Office.—*Apropos* of the agitation in the *Daily Telegraph* for an extension of all-night telegraph service, the following advertisement, which appeared in *The Times* of 21st inst., throws some light on the duties, hours and remuneration attached to all-day offices:—

POST OFFICE.—WANTED, a PERSON, male or female, or married couple, to undertake the duties of a small country post and telegraph office. Must find and pay one messenger or more, as required. Hours 8 a.m. to 8 p.m. on week days, 8 to 11 a.m. on Sundays. Rent 2s. a week. Salary allowed by Government £15 per annum and small commission on postal orders and Telegrams. No holiday allowed in the year, except on paying a substitute approved by the head office. Apply by letter to P.O., Scripp's Advertising Office, 13, South Molton-street, Bond-street, London, W.

Telephone Statistics.—A considerable extension of the operations of the National Telephone Co. (Limited) has taken place during the past year. The figures given below (from "The Electrician" Electrical Trades' Directory and Handbook for 1899) show the progress made from Dec. 31, 1893, to Dec. 31, 1898:—

Year.	No. of exchanges.	Total No. of call offices.	No. of lines.
1893	540	1,283	60,041
1894	582	1,347	73,338
1895	629	1,334	82,089
1896	698	1,279	94,407
1897	782	1,384	106,188
1898	853	1,665	120,144

Digitized by Google

Telephone Exchange at Auckland (N.Z.).—A telephone exchange was opened by the telegraph department last November, at Auckland, New Zealand. It was built by the Western Electric Co., and is on the multiple branching system, with self-restoring indicators, and pilot lamps to facilitate supervision. The present capacity of the switchboard is for 1,500 subscribers, but there is room for 4,900. The switchboard is divided into 15 sections, each served by one operator, who has, therefore, to attend to 100 subscribers' calls. Two sets of 3 storage batteries, charged by a gas engine and dynamo, furnish current for the operators' speaking circuits, the restoring circuits of the indicators, and the lamps.

Prizes Awarded by the Académie des Sciences.—The following are among the prizes awarded by the Académie des Sciences for the year 1898:—The Henry Wilde Prize to Dr. Charles A. Schott, in recognition of the value of his important work in connection with the terrestrial magnetic survey in the United States, published almost annually in the Annual Reports of the United States Coast and Geodetic Survey; the Gegner Prize to Madame Curie, for her investigations into the magnetic properties of commercial irons and steels, and her study of uranium and similar rays; the Houllevigue Prize to M. Edouard Branly, as already announced. There were only two essays sent in for the Kastner-Boursault Prize, awarded to the best work on diverse applications of electricity in the arts, industry and commerce. The first of these, on "Electric Traction on Railroads," by MM. A. Blondel and F. Paul Dubois, fills three volumes, and is a record of observations made during journeys in Europe and America, with a large amount of hitherto unpublished matter and much original work. M. Paul Janet was the other competitor for this prize, with a volume containing a *résumé* of his course on industrial electricity. The Commission having considered the two works of equal merit, the prize has been divided between them.

Lectures to Science Teachers.—By arrangement with the Technical Education Board of the London County Council, a course of lectures and laboratory demonstrations is being given by Dr. J. A. Fleming in the Pender Electrical Laboratory, University College, London, on Saturday mornings during the present Lent term, to about 20 or 25 head-masters, assistant masters, and science masters in London board schools and science schools. The subject is "Electromagnetism." The object of the course is, in the first place, to afford the teachers the advantage of seeing the best methods in lecture demonstrations, with the aim of improving their own teaching, and also giving them the opportunity to obtain experience in practical manipulation. The morning's work consists in the delivery of an experimental lecture by Dr. Fleming, followed by practical work in the laboratory. In the lecture course, such matters as the outlines of Maxwell's theory, Heaviside's system of rational units, and the processes of absolute measurement are being brought forward at an early stage; and methods of lantern projection, which has been a special study with Dr. Fleming, are fully illustrated and explained. In the laboratory, subsequently, the teachers, in groups of four, are taught to carry out quantitative exercises with simple, yet properly designed, apparatus, of a type which they can themselves subsequently use in their own teaching.

German Electric Tramway Statistics.—The *Elektrotechnische Zeitschrift* publishes, in its issue of January 5th, its usual statistical tables of the electric tramways in Germany. These are made up to September 1, 1898, and show that then 68 towns had electric tramways in operation. Since September 1st nine more electric tramway systems have been opened to the public, and the total of 77 may be compared with 61 at the end of the year 1897, and 44 at the end of 1896. In addition, 26 new lines are definitely projected or in course of construction, and in 35 places extensions are being laid down. The majority of these lines are on the overhead system, underground conduits being only used on some short lines in Berlin and Dresden. The "mixed" system, with overhead lines, and accumulators on the cars, is employed in Berlin, Dresden, Hagen (Westphalia) and Hanover, while the simple accumulator system has been adopted on one of the Berlin lines and at Hagen, Frankfort, Ludwigshaven and Türkheim, all these towns, with the exception of Ludwigshaven, being provided with either the overhead or "mixed" system as well. A line from Frankfort to Offenbach, 4½ miles long, opened in 1884, is still in operation, being one of the first experiments with electric tramways. The conductors are two slotted iron tubes, supported on poles, contact being made by means of four elliptical sliders pressed against the interior of the tube by flat springs. The following figures, all made up to Sept. 1, 1898, are interesting:—Total length of lines, 889 miles; total length of track, 1,205 miles; number of motor cars, 3,190; number of trailers, 2,128; capacity of generating plant, 33,333 kilowatts; capacity of power-house batteries, 5,118 kilowatts. Over 680 miles of line are in course of construction, corresponding to 830 miles of track.

Municipal Trading.—An important discussion on this topic is now taking place in the columns of *The Times*, and we extract the following from a letter which was contributed by Lord Wemyss on the 25th inst.:—

> Is it to the State or to municipalities that humanity is indebted for our marvellous progress in science, in invention, in material well-being? Assuredly not. It is to individuals and to private and commercial enterprise that all progress has been due. Thus, a great scientific discovery is made—take as an illustration the application of electricity to lighting, motor and other useful purposes. What happens? It is taken up by individuals who formed themselves into companies for the utilisation of electricity and its adaptation to our daily wants. This they did, not for the benefit of humanity, but in the hope and belief that it would pay. And, as in this, so in all inventions and discoveries that can be made available for the uses of society, and that, in the speculator's opinion, can be profitably worked. Had it not been for the hope and prospect of pecuniary benefit to be derived from the utilisation of scientific discoveries adaptable to the use of man, such discoveries would in many cases have been still-born, and assuredly would have so continued to be if the commercial speculator felt that as soon as his concern was seen to pay the State or municipality would take possession of his property and patent rights in the invention which he was, to use a current phrase, successfully running. Such action on the part of the State or municipalities tends necessarily to the checking of enterprise and to the arresting of human progress, for we may rest assured that, notwithstanding the wonders of scientific discovery in our time, we are ever on the threshold of further discoveries and inventions to be in their turn speculatively utilised for the benefit of man if private enterprise is left alone. I have referred to electricity. There we have conclusive evidence of the truth of the argument I have here advanced; for when Mr. Chamberlain carried through the House of Commons a Bill by which all electric companies might be compelled at the end of 14 years (extended in the Lords to 20 years) to part with their privileges and property to the State at the then estimated value of their plant, without reference to the market value of their property as a running concern, all advance in the utilisation of electricity for lighting and other purposes ceased. A committee of the House of Commons had to be appointed to consider the subject, and 40 years were substituted for the 20 in the Act as the time within which electric properties could not be acquired by the State. Let us then hope that we may see a joint committee of the two Houses of Parliament appointed and that it will put a stopper on municipal ambition and the speculating of municipal authorities with the ratepayers' money. Further, let them lay down, as a guide in such matters, the late M. Léon Say's wise axiom that "the action of the State should be so limited as not to interfere with private enterprise or limit personal responsibility."

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, January 27th.

PHYSICAL SOCIETY.

5 p.m. Meeting in the Rooms of the Chemical Society, Burlington House. Agenda: (1) "On the Equivalent Resistance and Inductance of a Wire to an Oscillatory Discharge," by E. H. Barton; (2) Exhibition of (*a*) A Dephlegmator, (*b*) A Temperature Tell Tale, by R. Appleyard; (3) "On the Volume Changes accompanying Solution," by T. H. Littlewood.

INSTITUTION OF JUNIOR ENGINEERS.

8 p.m. Meeting at the Westminster Palace Hotel, when Prof. J. A. Ewing, F.R.S., will deliver a Lecture on "Measurement of Elasticity."

SATURDAY, January 28th.

INSTITUTION OF ELECTRICAL ENGINEERS.

10:15 a.m. Students' visit to the Works of the Electric Welding Co., Hindon-street, Pimlico. Meet at the Institution, 28, Victoria-street, at the time stated.

WEDNESDAY, February 1st.

INSTITUTION OF ELECTRICAL ENGINEERS.

7:30 p.m. Students' Meeting in the Library of the Institution. Paper to be read, "Safety Fuses," by Sidney Ransom.

SOCIETY OF ARTS.

8 p.m. Ordinary meeting. Paper to be read, "The Cost of Municipal Enterprise," by Dixon H. Davies.

Digitized by Google

THE STANSSTAD-ENGELBERG ELECTRIC RAILWAY.

An order for the construction and working of a railway, connecting the village of Stansstad, on the Lake of Lucerne, with Engelberg, a favourite tourist resort 3,450ft. above sea level, was applied for and granted in October, 1890. It was not, however, until the autumn of the year 1896 that a company was formed with a capital of £80,000 for the purpose of building the projected line. As Stansstad is not connected with the Swiss railway system, the working of the line by steam would have been a very costly thing on account of the high carriage paid on fuel. It was, therefore, decided to build an electric railway, especially as an abundant water supply along the whole valley could easily and cheaply furnish the necessary motive power. The length of the proposed line being too great for an ordinary continuous current system, the polyphase system was chosen. The building of the line was commenced in May, 1897, and the railway was opened to traffic in October last. Messrs. Locher and Co., of Zürich, the well-known builders of the Pilatus Railway, were the contractors for the whole line, whilst the whole electrical equipment was supplied by Messrs. Brown, Boveri and Co., of Baden, in conjunction with the Société Suisse des Locomotives and the Société Industrielle Suisse of Neuhausen, who supplied the locomotives and rolling stock.

Map of Stansstad Engelberg Railway.

The line starts from the landing stage of the Steamship Company at Stansstad. Below we give a map of the line and a profile diagram. With a slight rise the line runs through Stans, and then, partly by the side of the road, with a maximum gradient of 2 per cent., to the village of Dallenwyl, where the river Aa is crossed by an iron girder bridge 115ft. long. The line then touches the village Wolfenschiessen Grafenort, from whence it follows the river, rising by means of a series of sharp curves, and a 5 per cent. gradient through a picturesque valley to Obermatt, where the power station is situated. From here a length of a mile is built on the rack system, ascending nearly 1,000ft., with a maximum gradient of 25 per cent. At one point the line is crossed by the road to Engelberg. The road being on a gradient, and lying slightly higher than the line, a draw bridge (shown in the illustration) had to be erected over which the road passes. The last portion of the line is mainly on the level, the rack ending about 1¼ miles below Engelberg. Room had to be made for the line in the last two miles by blasting away the rocks above the road, causing a series of sharp curves, the sharpest of which have a radius of 164ft.

Metre gauge (3ft.—3·4in.) is employed, the rails being of the ordinary Vignoles type, and weighing 26kg. per metre (52·3lbs. per yard). The length of each section of rail is 35ft., and there are 11 sleepers to the section. The sleepers are of rolled steel, and weigh 66lb. a piece. The rack is a so-called ladder rack, consisting of two parallel girders of rolled steel, into which the teeth are riveted. It weighs 105lbs. per yard, and is laid in 11½ft. sections. At the beginning and end of each steep gradient where a rack is employed, the end sections of the latter are left 7in. long, and have revolving teeth; these sections are supported at the ends on strong conical springs, so that the rack has here a certain amount of play, and the pinions can engage without rising out of it. The rails which form the third wire of the three-phase system are bonded at the joints by 8mm. Chicago bonds, being cross-connected at every fifth joint.

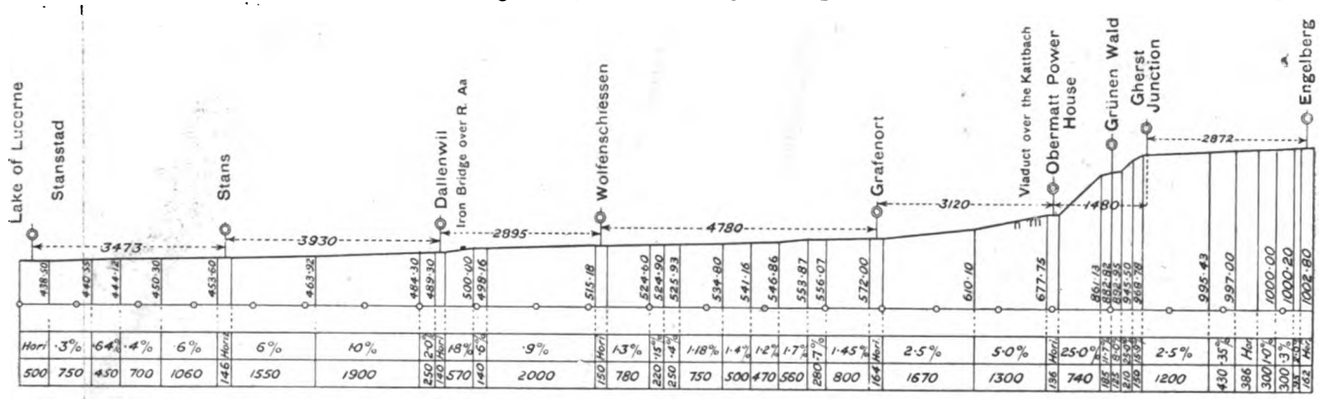
The stations are neat little brick and wood buildings, containing a booking-office, waiting-rooms and a goods shed. A carriage shed for eight cars, and a repairing shop, are situated at Stansstad. Both stations and repairing shops are lighted electrically, and the machine tools in the repairing shop are driven by a 5 H.P. induction motor, to which current is supplied from the trolley line through three step-down transformers.

Water-power for running the line is collected from a series of small springs which fill a reservoir of 660,000 gallons capacity, from whence a pipe line, 1,790 yards long, and buried in the ground, leads to the power station. The first 250 yards of the pipe line is of cast iron, with an inner diameter of 300mm. (11·8in.) and a thickness of 15mm. to 30mm. (0·59in. to 1·18in.). The remaining portion is of wrought iron with the same internal diameter, but a thickness of 7·5mm., 8mm., and 8·5mm. (0·295in. to 0·335in.). The available head is 1,280ft. A most suitable position has been chosen for the power station, viz., at Obermatt, at the foot of the rack, at the point where there is the greatest demand for power. The power-house, to which a locomotive shed is annexed, is built of brick, and contains space for three generating and two exciter sets. Two sets have been erected up to the present. The turbines built by Messrs. Bell and Co., of Kriens, are radial flow high-pressure Pelton wheels, with horizontal shafts. The output of each set is 180 H.P. at 650 revolutions, with a head of 1,250ft., and a flow of 11 gallons per second. The speed is controlled by Messrs. Bell and Co.'s patent high-pressure hydraulic governor. These turbines are directly coupled to three-phase generators of the revolving armature type, generating current at 750 volts and 32·5 revolutions per second. Shunt-wound dynamos of the Manchester type are used as exciters, each coupled to a 12 H.P. high-pressure turbine. They run at 1,700 revolutions per minute,

Digitized by Google

and their electrical pressure is 110 volts. The exciter turbines have no automatic speed regulators, and the exciting current is regulated by means of a rheostat in the field circuit of the main generators.

The switchboard, occupying one end of the machine room, is of white marble, mounted on an iron frame, and it is divided into three panels. The left-hand panel contains the field rheostat, and the exciter switches and measuring instruments.

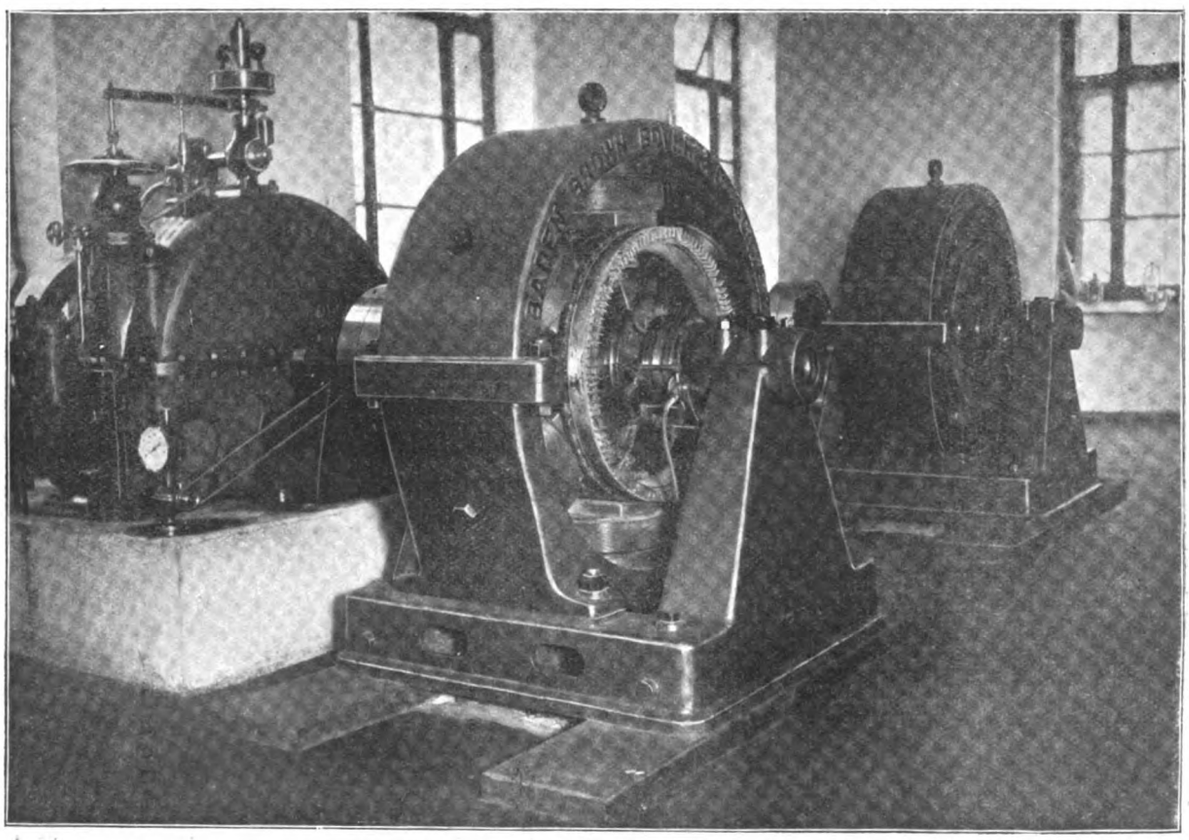


PROFILE OF STANSSTAD ENGELBERG RAILWAY.

NOTE.—The Dimensions are in Metres.

The two generator panels contain each a field rheostat, a three-pole switch, measuring instruments and synchronising lamps. At the top of the exciter panel is placed a three-pole switch for the step-up transformers, while the line and feeder switches are placed at the top of the generator panels. The generators run in parallel on three 'bus bars, and feed the trolley lines and feeders directly at 750 volts. On the back of the switchboard are placed the line fuses. The fuse is enclosed in a strong porcelain tube, at each end of which is a contact piece, so that it forms at the same time both fuse and switch. Behind the switchboard are placed three 30-kilowatt step-up transformers, raising the voltage from 750 to 5,200 volts. Here also is placed an automatic switch for interrupting the exciter current in case of an earth on the high-tension line. This was a stipulation made by the Federal Railway Department of Bern, as the high-tension line of 5,000 volts runs along the line for a distance of nearly seven miles.

The two trolley wires are of 7·5mm. hard-drawn copper wire suspended 8ft. 2in. apart and 13ft. 9½in. above the rails chiefly from span wires stretched between stout wooden poles. These poles also carry the low-tension feeder lines consisting of two 7·5mm. hard-drawn copper wires supported on double petticoated insulators. There are 2·6 miles of single feeders situated between Grafenort and the top of the rock, the section of the line where the power absorbed is greatest. The whole line is divided by section insulators into five insulated sections,



THREE-PHASE GENERATOR AND HIGH-PRESSURE TURBINES AT THE OBERMATT POWER STATION.

so that each section can be supplied with current independently of the rest of the line. At these points the contact lines are connected to the feeders by means of fuses of the same type as those used in the central station, the fuses being placed in watertight iron boxes screwed to the poles. As has been already stated, the high-tension line covers a length of

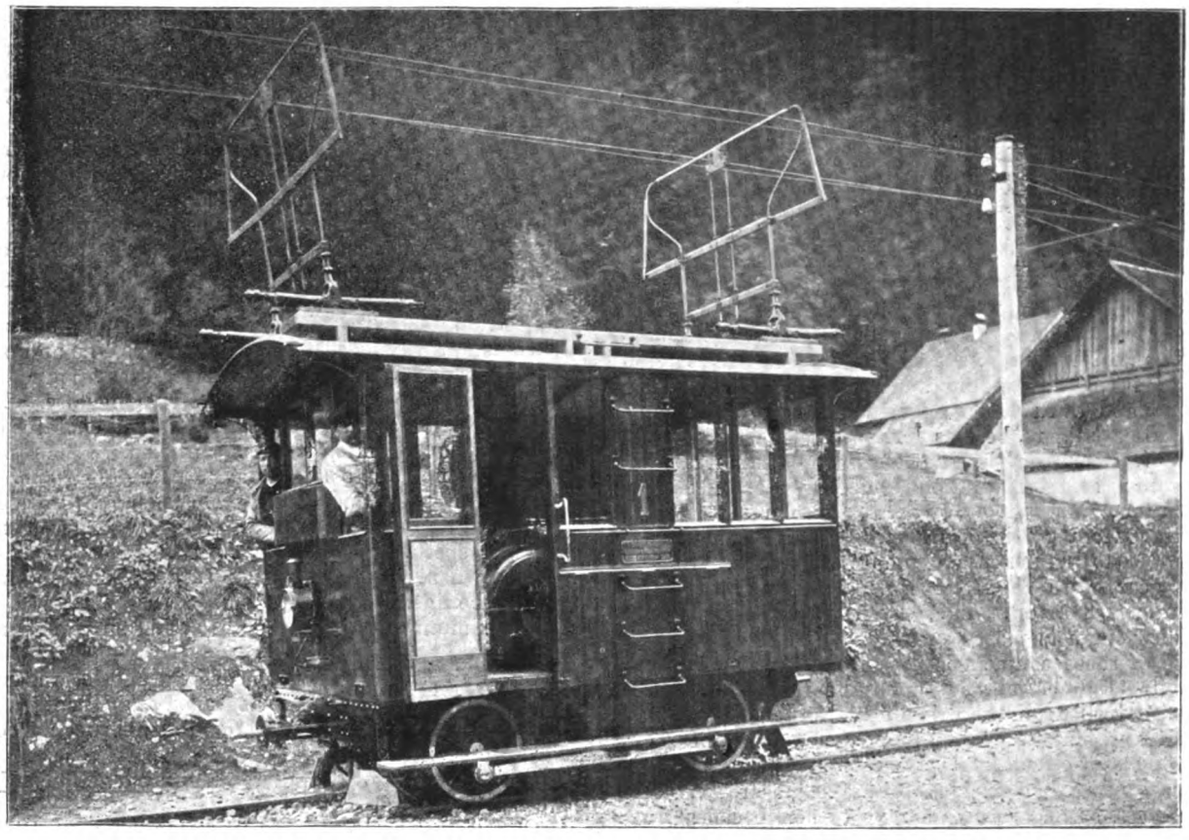
CROSSING OF RAILWAY BY THE STANSSTAD-STANS TRAMWAY.

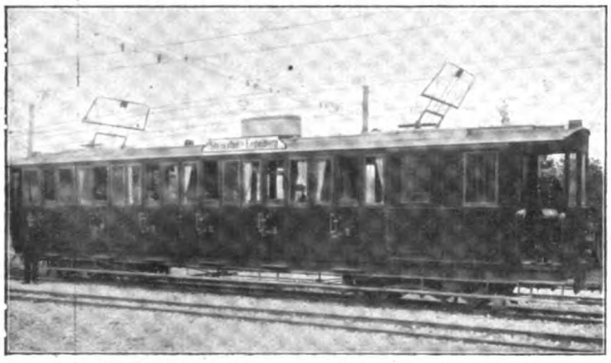


VIEW OF LOCOMOTIVE.

Digitized by Google

nearly seven miles. It is formed of three 3·5mm. hard-drawn copper wires, supported on separate poles along the track. To diminish the risk of a high-tension wire falling on the contact or feeder line the wires are supported on the far side of the pole, each pole being furthermore anchored by a stout iron cable. At Dallenwyl, a point approximately half-way between Stansstad and the power station, the high-tension current is transformed down by three 80-kilowatt, single-phase transformers to 750 volts, and the trolley wire is fed directly from these. A little tower built on the transformer chamber carries the high and low-pressure fuses.

At every road crossing, or where the high-tension line is crossed by another power line or telephone line, the wires are surrounded by a wide mesh net of galvanised iron wire, to prevent a wire from falling to the ground. The trolley-line poles are capped in the cast iron discs, carrying two insulators for the telephone circuit, which is a loop line of 2mm. silicium-bronze wire, crossed every 100 metres (109 yards) to prevent induction disturbances. It has been found that, so long as the insulation of the line is good, the telephone is nearly free from any induction noises. The State telephone line between Engelberg and Stansstad runs through the greater part of the valley parallel to the railway, divided from it by the breadth of the road only. It is only on wet days, when the leakage is naturally large, that a slight buzzing sound is heard; for the rest no more than the ordinary noises common to long distance telephony are noticeable. Great precautions had to be taken to protect the line against lightning discharges. The 750-volt lines are protected by Wurts patent lightning arresters, made by the Westinghouse Company, the high-pressure line by forked



Motor-Car on Stansstad Engelberg Railway.

lightning arresters placed at each end of the line, and each telephone by fuses and a short-gap lightning arrester. A point of interest on the line is the crossing with an existing continuous-current tram line near Stans, shown in the illustration.

The rolling stock consists at present of five motor-cars and two locomotives. The former, built by the Société Industrielle Suisse of Neuhausen, are four-axle bogie cars, having a length of 46ft., and weighing, unloaded, 14 tons. They have second and third-class compartments, and are capable of seating 46 passengers, besides having a luggage and mail compartment. The front bogie carries two 35 h.p. induction motors, running at 480 revolutions and 750 volts, and weighing about a ton. These motors are suspended by two double helical springs from the bogie frame, half the weight resting by means of two bearings on the driving axle. Single-reduction gear, with cast-steel wheels, is used, the gear running immersed in oil. The current is collected by two double sliding contacts placed on the roof of the car. The spring-base of these contacts is so arranged as to allow the sliding contacts to be laid flat upon the roof. The stator current is controlled on the driver's platform by a two-way switch under which are placed four enclosed high-tension fuses for the stator circuit of both motors. The third end of the stator winding is connected to the bogie frame. The rotor current is collected by double carbon brushes from the slip-rings, from whence it passes to the rotor resistance placed on the roof. The resistance is worked by a lever placed above the controller on the driver's platform.

The cars are heated and lighted electrically, current for the lighting being supplied at 100 volts by a small transformer placed in the luggage compartment. The heaters are placed, seven in series, under the seats, and are connected directly to the 750-volt line. Each car is fitted with two brakes: the one is a powerful handbrake applied to all the eight wheels of the car; the second is a pinion brake, acting on the pinion placed on the rear bogie, and is only used when the car is running over the rack. The maximum speed for which the cars are designed is 12½ miles an hour, and the speed is only varied by means of the rheostat in the rotor circuit.

The locomotives are similar in construction to those built by the Société Suisse des Locomotives of Winterther and Messrs. Brown, Boveri and Co. of Baden, for the Gornergrat and Jungfrau Railway.* Each locomotive is driven by two 75 h.p. induction motors, running at 650 revolutions and 750 volts, and each weighing two tons. The whole locomotive weighs 12 tons. Both motors are geared to a common shaft, which is again geared to the driving pinion running in the rack. The gearing is so dimensioned as to give the locomotive a speed of 3·1 miles an hour on the rack. By means of a friction coupling and connecting rod the motors can be geared to the driving wheel, making it possible to run the locomotive at a speed of 7½ miles an hour on the adhesion line. The rotors are controlled by a reversing switch in the stator-circuit and a common resistance in the rotor circuit. Three independent brakes are in use. The first is a hand-brake acting on the driving wheels. The second is a hand-brake, acting by means of four gunmetal shoes pressed on two wheels keyed to the driving pinion. The third is an automatic brake, which acts as soon as the speed of the locomotive exceeds 4¼ miles an hour on the rack. It consists in the main of a centrifugal governor keyed to the motor-shaft, which on acting releases a catch. By means of a falling weight the switch in the stator circuit is opened and the brake spindle coupled to the motor-shaft, so tightening the brake shoes on the driving pinion and on a pinion placed loose on the rear axle of the truck. By means of this brake it is possible to stop a train weighing 28½ tons and going at a speed of three miles an hour on the 25 per cent. gradient in a distance of 20ft.

The method adopted for working the line is as follows:—The motor-cars, which are designed of sufficient power to draw a trailer (a total weight of 26½ tons) up to a gradient of 2·3 per cent., run as far as the foot of the rack at Obermatt at a speed of 12½ miles an hour. From Obermatt the car is pushed up the rack, at a speed of 3·1 miles an hour, by one of the locomotives, and from the end of the rack the train runs on to Engelberg at the maximum speed and without the assistance of the locomotive. The down-coming train is coupled at the head of the rack to the locomotive, the coupling being released as soon as the train is on the 25 per cent. gradient, so as to be able to stop the car in a case of emergency independently of the locomotive. As the weight of the down-coming train tends to raise the speed of the motors above synchronism, so giving current back into the line and causing the turbines to run unloaded at an increasing speed, it was found necessary to load the generators artificially. This is done by inserting a water resistance in the generator circuit as soon as a down-coming train is signalled. This resistance is so dimensioned as to absorb a little more than the power given back into the line, so that the generators are loaded with a small surplus to enable the turbine regulator to keep the proper speed. The insertion of this resistance is only necessary when the down-coming train is the only moving object on the line.

The maximum capacity of the power station at present is as follows:—

1. One train, consisting of a loaded car and locomotive, *i.e.*, 28½ tons, on the rack between Obermatt and Ghent.
2. One loaded car, weighing 16½ tons, between Obermatt and Grafenort.
3. One loaded car and trailer, weighing together 26½ tons, between Grafenort and Stans.
4. One loaded car, weighing 16½ tons, between Stansstad and Stans.

* See *The Electrician*, Vol. XLI., p. 708.

Digitized by Google

To be able to meet the large traffic during the summer season, it is contemplated to enlarge the capacity of the power station to a maximum of 600 H.P., and to order three more motor-cars and one locomotive. The demand for facilities for transporting goods is increasing, and five goods cars are at present under construction, bringing the total up to nine.

In conclusion, our thanks are due to Herr H. Hänsler, who superintended the construction of the line for Messrs. Locher and Co., and who kindly supplied our representative with much of the information contained in this article.

THE POST OFFICE LONDON-BIRMINGHAM UNDERGROUND TELEPHONE CABLE.

Somewhat over a year ago* we notified the fact that the Post Office was laying an underground cable from London to Birmingham to supplement the existing overhead telegraph and telephone lines. We gave then a brief description of the cable, but by the courtesy of Mr. W. H. Preece, and with the assistance of Mr. G. W. Hook, who has charge of the laying of the cable, we are now able to publish further particulars and details, and to describe the methods employed for laying and jointing. The cable employed at first was a 76-wire cable, the separate wires being laid up in fours, but, after the first 20 or 30 miles had been laid, a 76 wire cable with wires laid-up in pairs was employed in preference. The remainder of the cable may, therefore, be described as follows:—

Copper conductors, 97 mils. diameter, weighing 150lbs. per mile, and with a resistance not greater than 5·852 ohms per mile at 60°F. Each conductor is insulated with a longitudinal wrapping of paper, and laid up in pairs, there being a strip of paper dividing the two wires of each pair. The "lay" in twisting the pairs is 1½in. The pairs are cabled in layers of 1, 6, 12 and 19 to make up the complete 38-pair cable, and between each layer and between the last layer and the lead sheathing is a lapping of paper tape. It is a noteworthy feature that no cotton is employed in the cable, in fact, no insulation of any sort except dry paper and air. After the cable has been thoroughly dried it is lead-covered, the lead sheathing having a thickness of 160 mils., and the diameter over all is slightly over 2½in. The whole of the cable is of the British Insulated Wire Co"s manufacture. Under the specification the capacity must be less than 0·065 microfarads per mile, and the insulation resistance above 10,000 megohms per mile; but, as a matter of fact, the insulation resistance is greatly in excess of the latter figure, some tests on laid and jointed cable having given 28,000 megohms per mile. Such a high insulation resistance is not by any means exceptional for paper-insulated telephone cables, but that it should have been maintained on a length of several miles of cable reflects great credit on the manner the jointing has been carried out.

The route along which the cable is laid is as follows:—Leaving London by the Edgware-road, which it meets at Cricklewood, it runs to Watford, entering the telegraph office there, thence through King's Langley and Hemel Hempstead to Leighton Buzzard, from which place also the lines can be used. Continuing, the line passes Fenny Stratford, Stony Stratford, Towcester, Weedon, Southam, Leamington, Warwick, and Hockley Heath, entering Birmingham by the Old Stratford Road. Besides Watford and Leighton Buzzard, there are stations at Fenny Stratford, Weedon and Leamington. At these places the cable from both sides ends in cast-iron cable-heads, whence it is brought to test-boards, where the wires can either be connected through or, by means of paraffined cotton wires, to the operating room.

FIG. 1.—CABLE READY FOR DRAWING-IN, SHOWING CLIP.

Three-inch cast-iron socket pipes carry the cable. These are laid in 9ft. lengths, and jointed with lead in the usual way. The cable being in 152-yard lengths, of which one yard is left over at each end for jointing and slack, a discontinuity in the pipe 4ft. 2in. long is left at the end of each 150-yard section of the route. This is afterwards bridged by a cast-iron sleeve, as will be explained. The pipes are laid at a depth of 2ft. under the footways and 2ft. 6in. under the roadways, with a wire for drawing in the pulling rope. In the event of a breakage in the wire, or a similar mishap, sweeps' rods are used to thread the pipe.

The whole line between London and Birmingham (about 112 miles) has not yet been completed. The pipes have been

The Electrician, Vol XXXIX., p. 596.

Digitized by Google

laid as far as Leamington, and the work of laying them between Leamington and the Birmingham Post Office is progressing, being divided in three sections. Cable has been drawn in up to three miles north of Weedon, and jointed completely up to two miles south of Weedon, *i.e.*, about 78 miles from London. Between London and Fenny Stratford, where some important road-lines meet, it is already working, and it has proved of considerable assistance as a reserve

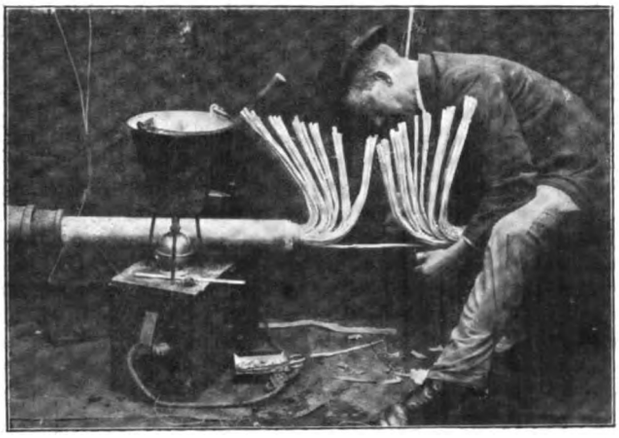


FIG. 2.—JOINTING THE FIRST PAIR.

during the recent gales. By the middle of next month it will be in working order as far as Weedon, where the route crosses the West Coast land-lines.

A very thorough system of jointing is in use, all the details having been carefully thought out by the engineering staff of the Post Office. The cable is drawn in by a rope attached to a clip, seen in Fig. 1, which is screwed on to the cable end.

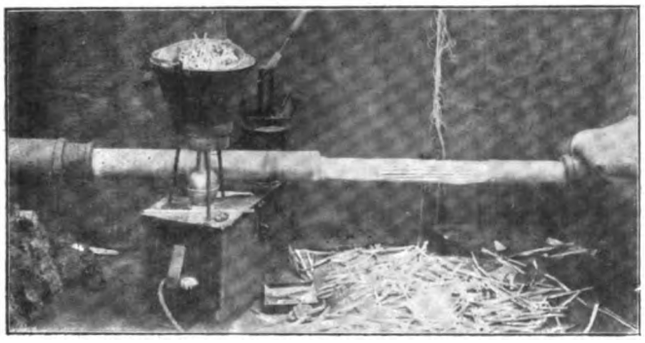

FIG. 3.—WIRE-JOINTS COMPLETED.

After having been drawn in, the end on which the clip was fastened is cut off, and the cable immediately sealed with a lead disc. This is done on account of the highly hygroscopic nature of the dielectric, the cable having to be sealed from access of the air from before it leaves the factory to the moment the joints are to be made. Before commencing the joint, a sleeve of 8in. 7lb. lead soil pipe is passed over the

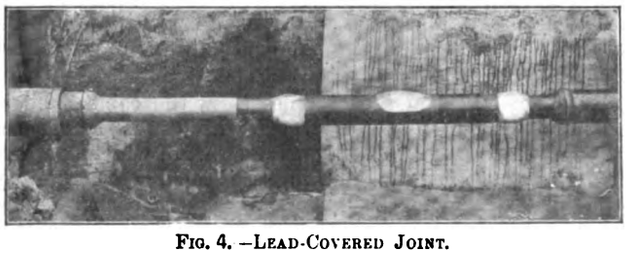

FIG. 4.—LEAD-COVERED JOINT.

cable, and a cast-iron sleeve over the iron pipe sufficiently long to bridge the gap after the cable-joint has been completed. The ends of the cables are then opened and separated, and the conductors jointed in the usual manner, wire by wire, pair by pair, and layer by layer. Before each copper joint is made, a paper sleeve is passed over one of the two wires and this is drawn over the completed joint. Fig. 2 shows the joint in process of construction. The sleeves are kept dry until wanted, by being placed in a tin in a bucket (seen in the illustration) which is heated by a spirit lamp. After all the wires have

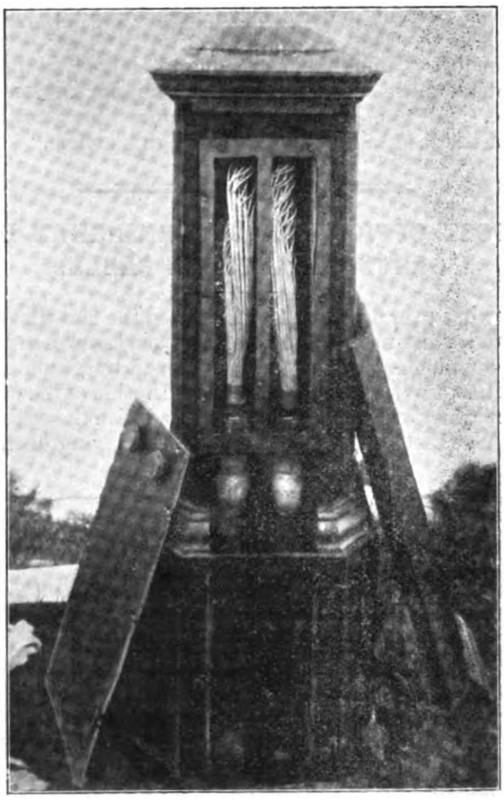

FIG. 5.—TEST-PILLAR (BACK).

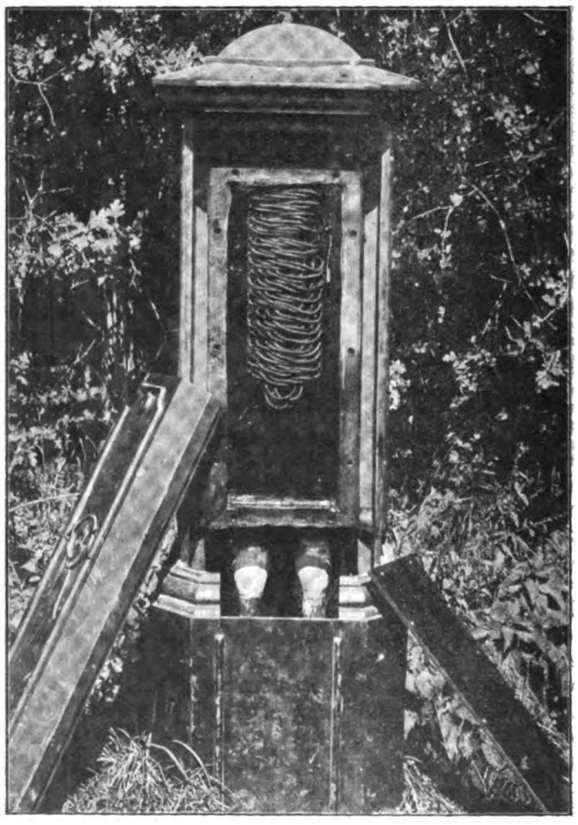

FIG. 6.—TEST-PILLAR (FRONT).

been dealt with, the joint presents the appearance shown in Fig. 3. It is then covered with a layer of paper tape and dried by heating it with a charcoal brazier until a piece of looking glass held over it indicates that no more moisture is coming off. The

Digitized by Google

time required for this drying process varies, of course, with the state of the weather. On a fine, dry day an hour is sufficient. The lead sleeve is then drawn over and jointed to the lead cable on each side by a plumber's joint. There is a small slit on the top of the lead sleeve, so that if necessary the joint can again be dried before this slit is sealed by another "wiped" joint. The completed joint is seen in Fig. 3. The iron sleeve is then pulled over it and jointed to the iron pipe on either side by a yarn and lead joint, just as the pipe itself.

After each day's work a test is made by the foreman to see that the wires are jointed properly in pairs, and a rough insulation test is made with a horizontal galvanometer and a 450-volt portable battery. If any indication of leakage is obtained on the galvanometer, the slit in the lead sleeve is reopened and the joint dried further. About every week a mirror galvanometer test of the insulation resistance is made.

There are test pillars placed at intervals of five miles along the route. As seen in Figs. 5 and 6, these resemble ordinary pillar boxes in outward appearance. Fig. 5 shows the back of the cable-head, where the cables are brought in, and Fig. 6 the front, where cross-connections are made. The cables are brought through brass sleeves in the cable-heads, and jointed to them by plumber's joints in the usual manner, the covers of the cable-heads also making an air-tight joint. Vulcanised rubber wire is used for the connections on the front of the cable-head. Up to the present no necessity has been found for utilising the dry air circulation method of drying the joints. If it is found that faults develop, however, arrangements will be made for pumping dry air through the cable at these testing-points. It has been found by experiment that air can be pumped through three miles of the cable, with a pressure of 36lb. per square inch.

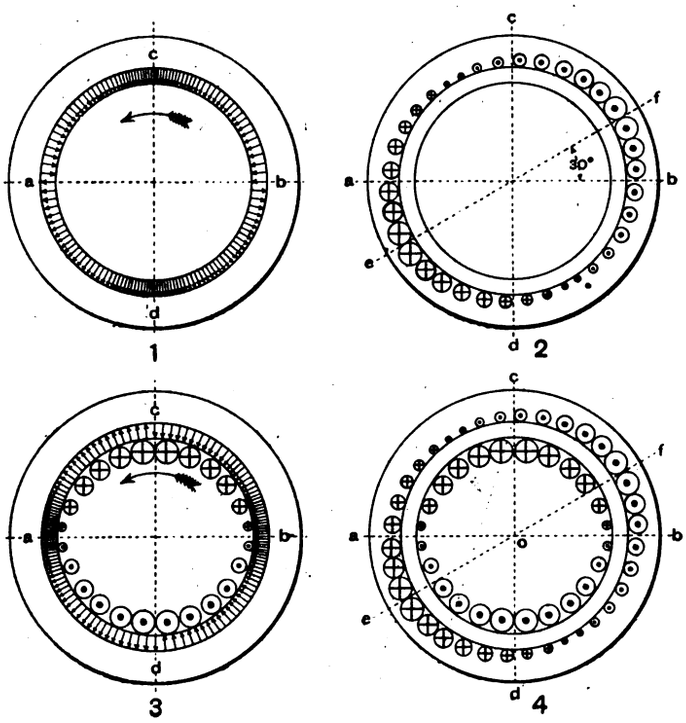
INDUCTION MOTOR DIAGRAMS.

BY C. C. HAWKINS, M.A.

Although the numerical quantities involved in induction motors are of such different magnitude that it is difficult to obtain exact determination in practical cases by means of diagrams, yet the graphical method remains the best means of gaining a clear insight into their working. The analysis of the induction motor by this method follows the same lines as the analysis of the transformer; the chief difference being that the magnetising current in the motor must be much greater than in the transformer, owing to the necessary air-gap in the magnetic circuit of the motor. Both cases have been treated at length by Mr. Steinmetz in "Alternating-Current Phenomena," and in England Mr. Atkinson's recent Paper before the Institution of Civil Engineers has again directed attention to the graphics of the induction motor. Yet with these exceptions (and the present writer acknowledges his indebtedness to them in particular), the graphical method has seldom been fully described, so that a more detailed building-up of its principles, accompanied by numerical illustrations, may still find a place.

(1) *Load Diagrams without Magnetic Leakage.*

For the sake of simplicity we assume at the outset that all magnetic lines due to the primary or field-winding pass through the secondary or armature-winding, and, similarly, that if the secondary were converted into a primary and excited, all its lines would pass through the original primary; in other words, magnetic leakage is assumed to be absent. The actual field present in the interspace between field-magnet and armature is due to the difference of potential at each point, which results from the magnetomotive forces of the field and armature ampere-turns. Let Fig. 1 represent a resultant two-pole field, such as would exist in an induction motor, at any one moment, as it rotates round the armature in the direction shown by the arrow. Then the instantaneous currents induced in a squirrel-cage armature are as shown in Fig. 3, where the relative strength of the currents at different positions are indicated by the size of the circles. The secondary ampere-turns so obtained would, if acting alone, produce a magnetic field of which the line of maximum induction, *a b* (Fig. 3), would be at right angles to the line of the maximum induction, *c d*, of the resultant field at the same moment. Evidently, therefore, the impressed ampere-turns of the primary must be of such strength and so placed that at each moment they not only balance the secondary ampere-turns, and so annul the field that these latter would produce, but leave a surplus of magnetising turns which actually produce the resultant field of Fig. 1. The ampere-turns in each case may be mentally regarded as concentrated in a plane coinciding with their line of maximum strength. Thus, in Fig. 3, the secondary ampere-turns may be grouped together in a vertical plane, *c d*, while at the same moment the magnetising ampere-turns which produce the field of Fig. 1 must be symmetrically placed on a plane, *a b*, at right angles to *c d*. In Fig. 5 let OX_μ represent the magnetising ampere-turns required to produce the actual field, and OX_s the secondary ampere-turns at right angles to OX_μ, while OX'_s are the primary ampere-turns required to cancel out OX_s. The completed parallelogram $OX'_sX_pX_\mu$ shows that in order to give the ampere-turns OX'_s, and, further, to leave a net sum of magnetising turns OX_μ, the primary ampere-turns must have the strength and position OX_p, their angle to OX_μ depending on the strength of the secondary



FIGS. 1, 2, 3 and 4.

ampere-turns (in the diagram 30°). Transferring this to a diagram similar to Figs. 1 and 3, we obtain Fig. 2, which shows the general disposition of the primary ampere-turns which must be produced by the several phases of current in the field-winding.* These cannot produce their full effect at right angles to *e f*, owing to the interaction of the secondary turns, and, as Fig. 5 shows, the general effect of the armature currents is to shift the line of maximum induction more nearly towards the line of maximum primary ampere-turns, and to reduce the strength of field everywhere below that which would be produced by the field-winding if acting alone.

If both sets of ampere-turns are filled in as in Fig. 4, one sees more plainly how the secondary ampere-turns are counterbalanced by the field-turns, and in order to fulfil more nearly the condition of no magnetic leakage, the air-gap should be reduced to a mere line, so that the layers of opposing currents clearly overlap each other. Thus Fig. 6 shows a pair of poles of a multipolar two-phase motor, equivalent to Fig. 4 split open along *d d*, with one circuit (shown by the full

* The actual currents in a two- or three-phase motor will not vary so gradually as shown, but the combined effect of the two or more phases must be the equivalent of the field-currents shown. Cp. Figs. 4 and 6.

Digitized by Google

circles) carrying the maximum current, while the other circuit (shown dotted) carries zero current; the phase angles are marked in terms of a complete period, and the diminishing or increasing sizes of the armature wires indicate the rise or fall of the current according to their position on the sine curve of the field in which they are immersed.

Fig. 5, like Fig. 4, was drawn to represent diagrammatically the complete system of a motor at some one moment, and, starting from this point, if Fig. 5 or the wires of Fig. 4 be rotated at the speed of the rotating field, they will still give a true representation of the condition of the motor at any other

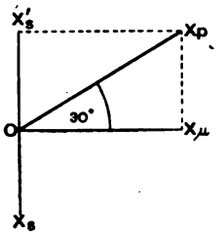


Fig. 5.

moment. But Fig. 5 can also be read as a clock diagram for the whole motor, applicable to a certain fixed diameter; if the lines OX_p, OX_μ and OX_s be regarded as rotating round O in the direction of the rotating field, *i.e.*, positively or counter-clockwise, and at its speed, their projections upon the vertical axis represent the instantaneous strengths of the primary, resultant and secondary ampere turns along any one diameter or line joining two poles in the armature, *e.g.*, as drawn in Fig. 5 along the vertical diameter *c d* of Fig. 1. The field due to OX_μ has such a direction across the armature that when OX_μ at any point is passing through zero

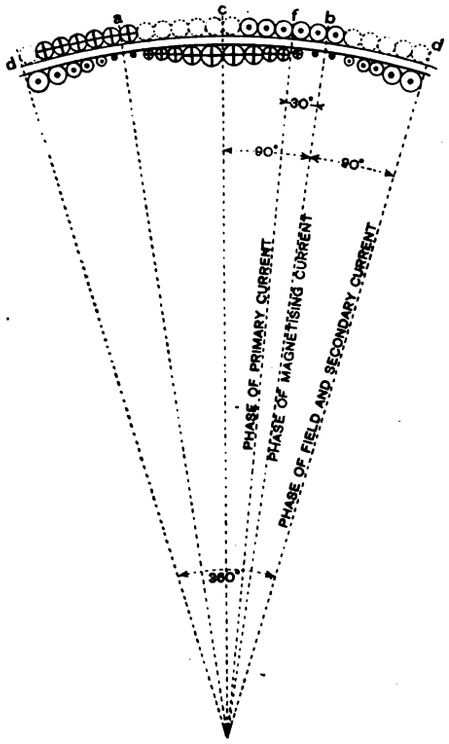

Fig. 6.

from a – to a + value, the current in the secondary wire at that point is passing through a – maximum to zero; hence OX_s lags 90deg. *behind* OX_μ, and the component OX'_s must, therefore, be ahead of OX_p. When so interpreted, the instantaneous values of OX_μ, OX_p and OX_s no longer remain constant, but vary after a sine law.

So far the representation in both cases is independent of the number of phases in the field or armature. We are, however, not so much concerned with either the spacial position of the total ampere-turns in the motor or with their instantaneous strength along any one fixed diameter; the coils of any one phase or circuit of the field are indeed fixed, but what we require to know is the current and voltage in them separately, and not the general effect of all the phases. In order to pass from the motor as a whole to one out of the two or more phases it is only necessary to alter the scale of Fig. 5 and interpret it as follows: If the length of the rotating line OX_μ represents the maximum strength of the magnetising current in one phase which, together with the simultaneous magnetising currents in the other phases, gives the resultant field, then the projection of OX_μ upon the vertical will give the share at any moment which the one phase of the field-winding takes in magnetising; *e.g.*, in a two-phase motor, when the projection of OX_μ on the vertical is zero in one phase, the field is due to the other phase and is still proportional to OX_μ. Similarly, OX'_s must be drawn to represent the maximum value in one phase of the current component by virtue of which that phase develops its proportionate share of the horse-power. The phases of OX_μ and of the field so far as it is due to OX_μ alone would coincide in point of time, but when OX_μ in one phase is zero the resultant field is acting, and OX'_s in the same phase is a maximum; it must therefore be plotted, as before, 90 deg. ahead of OX_μ. The rotating resultant field remains uniform as a whole, but since its distribution is assumed to be sinusoidal, and it has the same periodic time as the primary current, it induces in the coils, both of the field and armature, a sine wave of E.M.F. which has a phase and lags 90deg. behind OX_μ. As this E.M.F. in the field-winding is in the negative direction or is a counter E.M.F., it must be balanced by a component of the impressed E.M.F. in the positive direction, and this component will hereafter be called the "back" E.M.F., since it is required to balance the actual back E.M.F. induced in the field-winding. Thus Fig. 5 equally well represents the instantaneous strengths of current in any one phase of the field-winding.

Finally, as we only require to know the *relative phases* of the various current- and voltage- components, since these remain unchanged so long as the load remains constant, a single diagram suffices for each load, and it is permissible to plot either the maxima or the effective values of the components. It now remains to consider how the graphical diagram for one phase or circuit of a motor with no magnetic leakage is to be drawn for any load; and at the outset it must be pointed out that, owing to hysteresis, the preceding statement that the phases of OX_μ and the field due to it coincide is not absolutely true, although for a preliminary general explanation it is sufficiently accurate.

(*To be continued.*)

GRAVITY-ELECTROLYTIC PROCESSES FOR THE PRODUCTION OF CAUSTIC SODA.

BY G. H. ROBERTSON, F.C.S.

Processes for the production of bleach and caustic soda by the electrolysis of a solution of common salt are exceedingly numerous, but it is evident from the attention which the matter still receives at the hands of inventors that a thoroughly satisfactory solution of the problems involved in conducting this operation on a commercial scale has not yet been obtained. In the early days, effort was mainly directed to obtaining a satisfactory diaphragm which should keep the anions and cations, separated by the current, from recombining. Then the anodes were thought to contain the key to the situation, and much ingenuity was expended in endeavouring to cheapen the cost of their production, and render them less destructible by the products of electrolysis. But it was realised at last that what was wanted was some method for removing the anions and the cations from the bulk of the solution as fast as they were separated by electrolysis, and in order to effect this Kellner introduced his well-known process in which a moving mercury cathode combines with the alkali metal as soon as it is released, and transfers it to a second vessel containing water, in which the metal forms caustic

Digitized by Google

soda, while the E.M.F. due to this reaction goes to aid the E.M.F. which is required to decompose the salt solution. Other processes of this kind have been introduced, but mercury is costly, and there are other objections to its use, so attempts have been made to devise processes in which the continuous separation of the anions and cations should be effected by the force of gravity instead of that of chemical combination. The latest of these is that which has been recently introduced by the Oesterreichischer Verein für Chemische und Metallurgische Produktion, in Bohemia. Before describing it, it may be as well to give a short account of the principal processes of the kind which have preceded it, and the disadvantages from which they are alleged to suffer.

The earliest of these was that devised by Cuttens in 1892. He employed a pump to remove the chlorine as soon as it was formed, while the caustic solution which is formed round the walls of the cell (cathode) was allowed to sink to the bottom by its own gravity, from whence it could be drawn off at intervals. During this process, strong salt solution is forced into the lower part of the cell at a point below the cylinder which surrounds the anode, and ascending this, it leaves the upper part of the cell to be strengthened by passing over rock salt. In this process the layer formation of the electrolyte due to the difference in density between the anions and the cations is destroyed, owing to the disposition of the anodes, and the way in which the electrolyte is fed in, and the projection of the anodes contracts the space in which the layers can be formed.

Four processes were introduced in 1893. G. Baily and M. Guthrie suggested a process in which a pair of very porous screens were interposed between the anode and cathode so as to enclose a space into which the electrolyte was fed continuously, and overflows were arranged near to or behind the electrodes. The electrolyte was intended to flow from the centre to the electrodes at such a rate as to prevent diffusion, but there was a difficulty in effecting this, and the solutions of different density into which the liquid was separated by electrolysis would not maintain a vertical position, but tended to form horizontal layers with consequent intermixture.

Hurter, Auers and Muspratt introduced a density process, but the apparatus hinders the formation of layers, as, owing to the position of the anodes and the use of the whole of the cell wall as cathode, the evolution of gas from anode and cathode must generate movement of the liquid which will destroy layer formation. Moreover, the process was primarily devised for discontinuous working, and no means were provided for introducing fresh electrolyte into the closed anode compartment, so that if the process were worked continuously with the apparatus described, fresh electrolyte would have to be introduced into the open cathode compartments, which would of necessity break up the layer formation, while the liquid in the anode compartments would become poorer and poorer, with the result that secondary decomposition of water would take place with useless consumption of current.

Richardson, in order to overcome the disturbance of the electrolyte caused by the escape of chlorine gas generated near the bottom of the anodes, proposed to interpose horizontally between the electrodes a screen of slips of glass which overlapped like the slats of a Venetian blind, leaving spaces between them for the passage of the current. The caustic solution collects near the cathodes at the bottom of the cell, and as the process is not arranged for continuous working, the whole of the alkali formed cannot be removed before fresh solution is run in.

Dr. W. Bein brought out a discontinuous process, and arranged the anodes and cathodes side by side in special divisions of the decomposing trough, which communicated under the surface of the liquid. By means of a device the two layers of liquid can be separated, and the operation stopped when the electrolysis has proceeded so far that the cathode liquid is about to enter the anode compartment. The process requires careful supervision, and, moreover, the complication of the apparatus involves technical difficulties. In 1897 this process was rendered continuous by substituting means for continuously supplying fresh electrolyte to the cell at the place where in the older apparatus the valve was situated which maintained the separation of the liquid into layers, and in this way a separating layer is maintained between the anode and cathode liquids. Moreover, the electrolyte thus introduced caused the anode and cathode liquids to move to their respective outlets at a rate proportional to its flow. The advantage which it was hoped to attain by this apparatus—*i.e.*, a continuous working—is not realised, since the admission of fresh electrolyte into the space between the anode and cathode is not favourable for the formation of layers, and it is impossible in practice to so regulate the efflux from the anode and cathode compartments that the quantity flowing away from each shall be in constant proportion, and, in consequence, the working is very irregular. If the influx into the anode compartment be restricted, the liquid therein soon becomes so dilute that secondary decomposition of water ensues, and there is useless consumption of current.

In 1894, Carmichael designed an apparatus based on much the same principle. He employed a specially designed diaphragm which afforded a free communication between the anode and cathode compartments, and the fresh electrolyte was fed in between the anode and the diaphragm so that the alkaline solution passed through to the upper part of the diaphragm, and flowed back through the communication in the diaphragm into the cathode compartment, and thence to the outlet. In addition to the disadvantage occasioned by the use of diaphragms, this process suffers from the defect that the introduction of the electrolyte into the space between the electrodes destroys the layers formed by the separation of the electrolyte into solutions of different density, and the impoverishment of the anode liquid and the consequent waste of current are not avoided.

It is claimed that the new density process, which has been recently introduced by the Oesterreichischer Verein differs from those already described, and avoids their disadvantages. Now when an alkaline solution, particularly a chloride of an alkali, undergoes electrolysis, there is a constant passage of hydroxyl ions towards the anode compartment, while the product of the reaction of the cations with the water collects as an alkaline solution around the cathode, and gradually spreads to the anode compartment; and if the electrolysis is carried too far, the alkali formed around the cathode spreads to the anode liquid, and chlorate is formed which gives rise to injurious secondary reactions. When the alkaline solution has a higher density than that of the electrolyte, and than that of the liquid in the anode compartment, it is obvious that the anode should be arranged at a higher level than the cathode, whereby full use is made of the difference of density between the anode and cathode liquids for separating them, and with them, of course, the products of the electrolysis. By the introduction of fresh electrolyte above the anode, and the consequent circulation of the electrolyte in a direction opposite to that of the migration of the hydroxyl ions, the layer formation is not interfered with, and the alkaline liquid can be withdrawn from an overflow pipe. These principles are embodied in the new apparatus in which the electrodes are placed side by side, and if necessary, at different levels. The anode is covered by a bell which extends below it, and fresh electrolyte is fed into this compartment continuously, while the alkaline lye produced is continuously removed from the cathode compartment, and the layer formation of the anode and cathode liquids is maintained without the use of a diaphragm, so that the products formed at the electrodes are continuously separated. How far the anticipations formed of the new process will be verified in practice remains to be seen.

American Government Cable Steamer.—Orders have been issued by the War Department for the purchase at once of an iron ship of from 1,000 to 1,200 tons burden to lay cables to connect the islands of the Philippines. The Department has already ordered 166 miles of cable for this purpose, which will take about 6,500 cubic ft. for coiling. The cable ship must accommodate on the forward deck, says the *Electrical Engineer* of New York, the "giving out" machinery, which will weigh from 15 to 20 tons, and the accessories, weighing from 5 to 10 tons. The ship is to be kept on station as a cable steamer, or will, if necessary, be used as a transport.

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal 1861—1878).

Published every Friday, Price Sixpence; Post Free, Sixpence Halfpenny

Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone: 949 Holborn. *Telegrams:* "Electrician Newspaper London."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "The Electrician," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "The Electrician" *Printing and Publishing Company, Limited, and be crossed "Coutts and Co."*

All Editorial letters to be addressed to The Editor.

All letters for insertion in "The Electrician," *or containing questions, must be accompanied by the name and address of the writer as evidence of good faith. No notice whatever is taken of anonymous communications.*

The Electrician *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices, as above.*

New Volumes of "The Electrician" *commence in April and October.*

Subscription Rates.—The Rates for Subscriptions to "The Electrician" are as under:—

	Year	Half-Year	Quarter	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Postal Union ..	30s. 0d.	16s. 0d.	8s. 0d	

"The Electrician" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

Trade Advertisements *intended for the current issue must reach the Office not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday. Wrapper Advertisements by Wednesday morning.*

Official Announcements, Auctions, *and* Small Advertisements *accepted up to 6 p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct o "The Electrician" *Printing and Publishing Company, Limited. The well-known* "Electrician" Series *of Standard Electrical Works at present consists of—*

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young, M.I.E.E. Price 10s. 6d., post free; abroad 11s.

THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By Messrs. H. K. C. Fisher and J. C. H. Darby. Price 6s. net; abroad, 6s. 3d.

BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH. Edited by C. E. S. Phillips. With an introduction on the history of Crookes Tube and Röntgen Ray work, and a chapter giving "Practical Hints," on the subject.

THE POTENTIOMETER AND ITS ADJUNCTS. By W. C. Fisher. Price 6s., post free.

LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS. By F. C. Raphael. Price 5s., post free.

MOTIVE POWER AND GEARING. By H. Tremlett Carter. Price 12s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson. Price 12s. 6d., post free.

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. Fleming, M.A. F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. **Vol. I.** Price 12s. 6d., post free 13s. *Vol. II. is nearly ready.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. Fleming. VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. NEW EDITION. Price 12s. 6d., post free. VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. 93 original illustrations, price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. Snell. 10s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. George Gore. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. Weymouth. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By Gilbert S. Ram. Price 7s. 6d., post free.

A POCKET-BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Gruphl and H. M. Kilgour. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d., post free. New edition in the press.

"THE ELECTRICIAN" PRIMERS. In Two Vols. Paper covers, 2s., post free, 2s. 2d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d.

WIRELESS TELEGRAPHY: Signalling across Space without Wires by Electric Waves. By Dr. O J. Lodge. Enlarged Edition. Price 2s. 6d. net.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c. By A. C. Curtis-Hayward, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont. Price 2s. 6d., post free.

FULL CATALOGUE POST FREE ON APPLICATION.

"ELECTRICIAN" SERIES FORTHCOMING BOOKS.

ELECTROMAGNETIC THEORY, VOL. II.—By Oliver Heaviside. The second volume of this important work is in an advanced stage, and will be ready shortly.

PRACTICAL TELEPHONY.—By Dane Sinclair and F. C. Raphael.

PRIMARY BATTERIES.—A work on this subject will shortly be published, bringing the theory and practice of the Primary Battery up to date. The book will be fully illustrated.

SECONDARY BATTERIES.—By E. J. Wade. Fully illustrated. The Author in this work will deal briefly with the theory and fully with the chemistry, design, construction and manufacture of secondary batteries or accumulators.

"THE ELECTRICIAN" WIREMAN'S POCKET-BOOK.—"The Electrician" Company will shortly publish a valuable pocket-book for the use of those engaged in wiring work, both external and internal.

CARBONS FOR ALL ELECTRICAL PURPOSES.—By Francis Jehl. A work will shortly be published dealing fully with the manufacture of carbons for all electrical purposes. The book will illustrate the machinery and apparatus used in carbon manufacture on the Continent and in America, and will give the latest practice in this important subject.

THE ELECTRIC ARC.—By Mrs. Ayrton. This work will shortly be published, and will contain an historical sketch of the early experiments on the electric arc, as well as the important results of recent research.

SPECIAL NOTICE.

With this issue of "THE ELECTRICIAN" is published a Supplement Sheet Table of ELECTRIC RAILWAYS AND TRAMWAYS IN THE UNITED KINGDOM for 1898-99, which all purchasers of the Paper should receive gratis. Complaints of non-receipt should be promptly made to THE PUBLISHER.

NOW READY.—Vol. XLI. of "The Electrician," bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

A complete set of the Second Series of "The Electrician" can now be supplied. These sets are very scarce, and early application should be made.

SOME ASPECTS OF BRITISH ELECTRICAL INDUSTRY.

We publish as a supplement this week our annual Table of the Electric Railways and Tramways of the United Kingdom, giving particulars to date of the lines in Operation, in Progress of construction and Projected. It will be seen that there are 34 lines in operation, 27 under construction, and no less than 93 projected, making a total of 154 lines of all descriptions. At the end of 1897 the numbers were 23 lines in operation, 25 in progress, and 83 projected. Thus there has been an increase of 48 per cent. in the number of working lines, and of 90 per cent. in the total number of lines of all classes. Again, whereas the gross mileage of the lines in operation at the end of 1897 was 140 miles, the mileage of working tramways and railways to-day exceeds 240 miles, showing an increase of 71 per cent. in twelve months. A careful examination of the data afforded by this year's table, and a comparison of these data with the corresponding data for previous years, will show that the British electrical manufacturer and contractor is gradually awaking to the importance of electric traction as an opening for trade, and is receiving a steadily increasing share of this class of work in the United Kingdom. From the first, two or three leading electrical firms have undertaken important contracts, chiefly for the heavier class of lines represented by the City and South London Railway and the Liverpool Overhead Railway, but there is no denying that for some time the foreign manufacturer had it nearly all his own way with street tramway electrical equipment. We have long insisted upon the necessity for the British manufacturer to standardise his electrical equipment in order that he might be able to market his goods at a price that could compete with the highly-standardised American products. It is gratifying to notice that this is now extensively being done by all the leading firms who

Digitized by Google

manufacture electric traction plant. There were two obstacles formerly in the way, viz., the lack of experience on the part of the manufacturer as to the best designs to adopt for standardisation, and, secondly, the insistence of each individual consulting engineer on the adoption of the special designs evolved in his own office. The British custom of entrusting the details of an engineering specification to a consulting engineer has many good points, and we do not wish to see it abolished; but there is no doubt that it often possesses features which might advantageously be eliminated. One of these is the free hand the consultant possesses of introducing his own pet ideas—often very costly fads—into the design of the plant to be supplied. The unhappy contractor is thereby put to unnecessary expense, either in submitting two alternative tenders, one including the fads and the other based on common practice, or else in altering the patterns of his plant to suit the innovation. We repeat, we are glad to see very marked indications that all the principal British manufacturers who are making traction plant are standardising sizes and designs; and we regard this as a prelude to a very considerable increase in the volume of British home trade in this class of manufactures. It is also pleasing to observe that the vigorous tone of British trade in traction plant is but one phase of an all-round expansion of British electrical engineering industry. We have alluded on previous occasions to the great activity that prevails in the engineering workshops of the country; and we are assured, in many quarters, that there are indications of a general and permanent expansion of this department of industry. If home electrical industry be any index of the general conditions, these indications, indeed, are not misleading.

Turning now from the home aspect of British electrical industry, let us consider some of the points which have been brought before the public of late in regard to our foreign trade. We may notice, in the first place, the instructive, if somewhat curious, array of consular opinions on the subject recently displayed by our esteemed contemporary, the *Daily Chronicle*. A whole column of that newspaper was filled with extracts from the latest reports from Her Majesty's consuls in various parts of the world. Some 200 reports were searched, and 37 extracts were given, our contemporary remarking in its prefatory paragraph that "the extracts . . . . are by no means exhaustive; there are plenty more to be had of the same tenor." The general tone of these extracts is sufficiently indicated by the following samples:—

Argentine Republic.—Continental merchants are always more willing to meet their customers' wants than British, who will endeavour to foist their ideas and their stock on their customers, without sufficiently heeding the latter's needs. Cases of goods should be marked in kilos and metres. (8648-66, p. 10.)

Brazil (Rio de Janeiro).—The conservative system of British manufacturers often prevents them making new patterns to meet the needs of foreign markets. (8648-80.)

France (Cherbourg).—Notwithstanding the reputation for good make still enjoyed by Great Britain, the difficulty of procuring British-made goods suitable to local tastes, the impossibility of unravelling the mysteries of British price lists, and the absence of all flexibility in British commercial custom, almost close the half-shut door to British imports. (8648-57, p. 5.)

Germany (Dusseldorf).—British commercial men still labour under the old delusion that English weights, measures, classes of goods, tools, implements, and so on, which meet with English requirements and tastes, will work all over the world (8648-68, p. 7.)

Japan (Nagasaki).—English producers have queer notions of enterprise. The English manufacturer, as a general rule, will take no risk. (9044-6, p. 10.)

Netherlands (Amsterdam).—British manufacturers must accommodate themselves more to the needs of their foreign customers. The use of the metric system is imperative. (8648-76, p. 9.)

Norway.—British goods might find more ready sale if manufacturers would take pains to cultivate the market. There are about seven German commercial travellers to one English. (8648-141, p. 15.)

United States (California).—In electro-plate and silver, the stubbornness of the English manufacturers in ignoring the particular requirements of the American market handicaps the sale of English goods. (8648-174, p. 21.)

Broadly speaking, two principal complaints pervade these extracts: firstly, as to the non-adoption of metric currency and measures to suit local trading; and, secondly, as to a certain stiff-necked disregard for local requirements in the class of goods supplied. Where these complaints hit the British electrical manufacturer, we feel sure he will pay attention to the matter; but we do not think there is any ground for the second complaint, at any rate, as regards the generality of these firms. Indeed, through the exceptional willingness of the British contractor to adapt his patterns and designs to the local and special requirements of his customer, he is placed in an especially favourable position to compete in colonial and foreign markets. Thus, while standardisation is desirable at home—to meet the uniformity of home conditions—abroad, the variety, and even heterogeneity, in the conditions places at an immense advantage the manufacturer who is willing to adopt special and local types of design in his manufactures. And, as a matter of fact, the British electrical manufacturer—whether from this cause alone, or, as we suspect, from the general superiority of his wares—still holds the bulk of the colonial contracting work, especially in South Africa. Our contemporary reflects that, notwithstanding the sadness on the consular brow, "we are making wealth at an appalling rate." While not ourselves "appalled," we are willing to concede that the wealth derived from our colonial and foreign engineering trade is rapidly on the increase; and we regard this fact as an indication of the persistent suitability of British machinery—including, of course, every description of electrical plant—to meet local and national conditions in all parts of the world.

OPEN CONDUIT ELECTRIC TRACTION AT WASHINGTON.

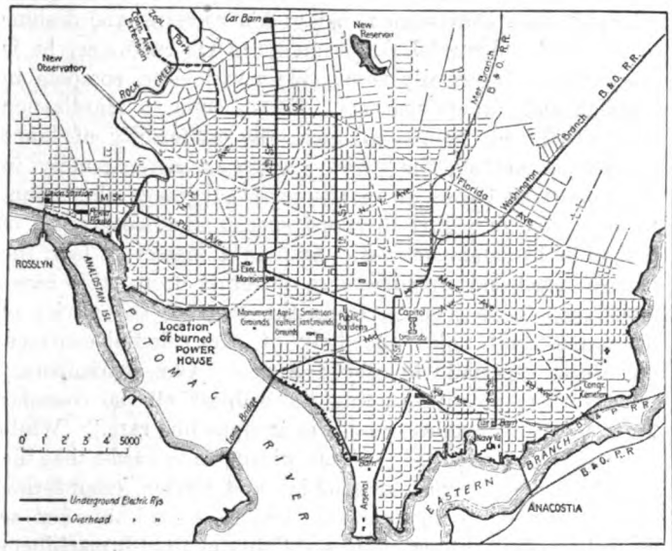
Washington, the capital of the United States, has afforded many interesting lessons in tramway traction. The whole of the district of Columbia, which is controlled by the City Council, is well served by tramways, but many years ago the authorities decided to prohibit the overhead trolley system within this territory. Consequently the cable haulage system and the electric conduit system have been very extensively developed there. Indeed, more has been learned in Washington in regard to the construction and working of electric conduits for tramways than in any other part of the world, and the success of the system ultimately evolved has led to its adoption in other American cities, notably in New York. Many of the Washington lines extend beyond the district of Columbia into Maryland and West Virginia, in which two States the overhead trolley is permitted. At the boundary lines these tramways change from the conduit to the trolley system, and thus ample experience has been gained as to the working of such composite systems. It will be remembered that similar composite systems have on several occasions been proposed for British cities, where the tramway systems extend to the rural districts.

One of the most important traction concerns in Washington is the Capital Traction Co., which in 1897 had 36 miles of track, of which 21½ miles were worked by cable haulage and 14½ miles by electric conduit. The gauge is 4ft. 8½in., and the tracks were laid with 50lb. and 80lb. rails. There were 450 cars, of which 25 were electric motor cars, 98 cable grip cars, and 327 trailers. At the power station, the location of which is shown in the map accompanying this article, there was station plant aggregating 1,600 H.P. On September 29, 1897, the whole of this station was destroyed by fire, and the entire cable and electric system was thrown out of gear, the cars having to be temporarily run by horses. Within four days of the fire the directors decided definitely to adopt the underground conduit system for their lines, which had previously

Digitized by Google

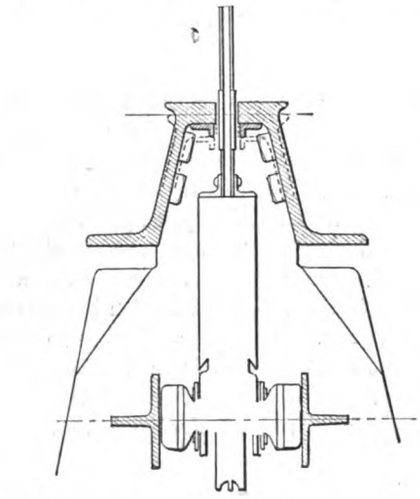
been worked by cable haulage, and thus to work the whole of their system by electricity. Particulars of the electric construction work, both in converting the old cable conduits to the electric system and in the construction of the new power house, have recently appeared in the *Electrical World*, of New York, to which we are indebted for the following details, as also for the illustrations which accompany this article :—

Reconstruction of the Tracks.—The track system adopted was the same as that in use by the Metropolitan Railroad Co.

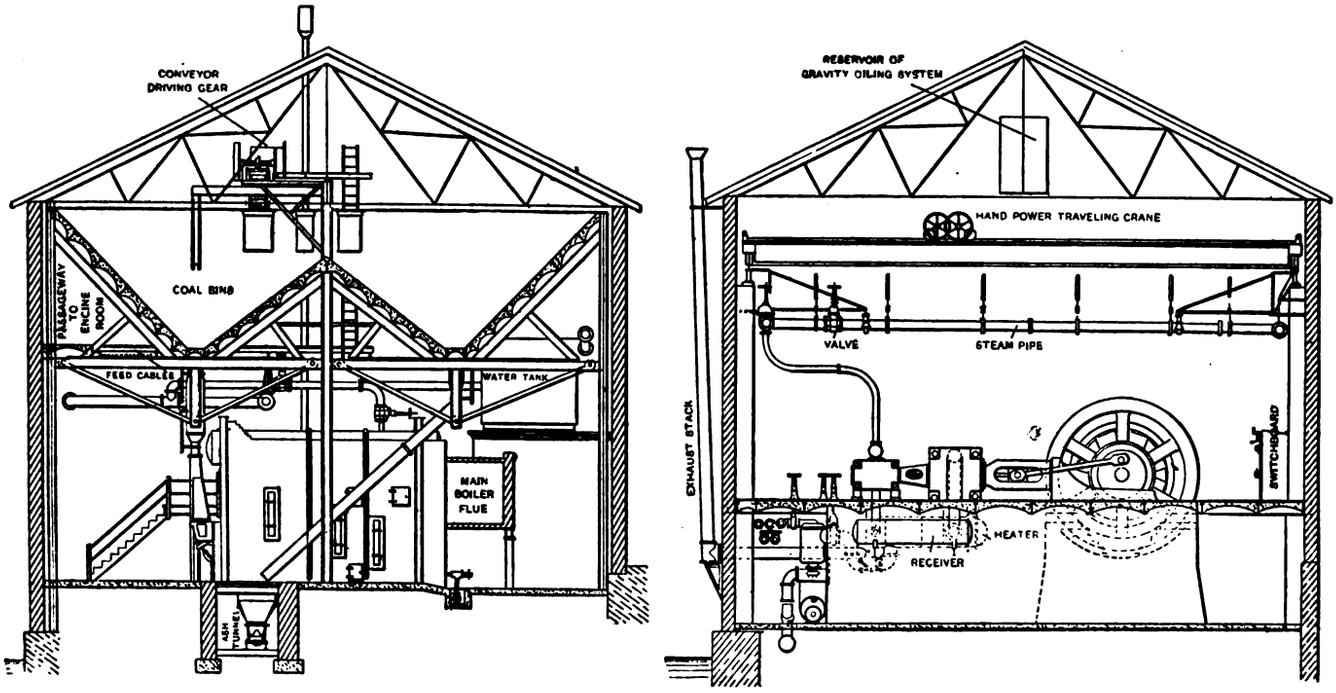


MAP OF THE CAPITAL TRACTION COMPANY'S SYSTEM AT WASHINGTON.

in Washington, and by the Metropolitan Street Railway Co. in New York City, with such changes as were necessary to adapt it to the existing cable tracks. Twenty-two miles of track have been changed over, including the Seventh-street line, which was kept in operation by cable while the change was being made; the Love conduit system on U-street will later be rendered uniform with the rest. A 24-way conduit for the electrical cables was laid midway between the two tracks, except where deflected by existing pipes and ducts, the material used being vitrified clay pipes, and wrought-iron cement-lined pipes are laid in concrete in the ordinary way. Temporary tracks were laid down for the horse cars on Pennsylvania-avenue and Fourteenth-street, so that the track work could be carried on without interruption. The cable conduit—18in. wide by 38in. deep—was fortunately made of concrete, plaster-lined, and without any inside metal sheathing. Entrance to it was obtained by means of manholes at intervals of 31½ft., running from the slot rail to the outer track rail. The conductor rails for the new electrical work are of steel, T-shaped, 4in. by 2in., weighing 23lbs. to the yard, and having the conductivity of 300,000 circular mils. of copper. They were cut into 31ft. 6in. sections to span the distance between these manholes in which the insulating supports for the outer rail were placed. To hold the other conductor rail a small handhole was put in immediately across the slot from the manhole, and to give an intermediate support at the middle of the rail length a pair of similar handholes was put in midway between manholes. The conductor rails were inserted through slot hatches which were placed at intervals of about 800ft. The porcelain insulators are supported by cast-iron caps with ears, which are bolted to the foot flanges of the slot rails. The holes for these bolts were made by punching machines as soon as the excavations for the handholes had been made. The two holes in the web of the slot rail for the attachment of each cast-iron handhole frame were made by a specially designed drill let into the excavation and backed up against the track rail. Knock-down frames were then placed



SECTION SHOWING SLOT-RAILS, CONDUCTOR RAILS AND CONDUCTOR PLOUGH.

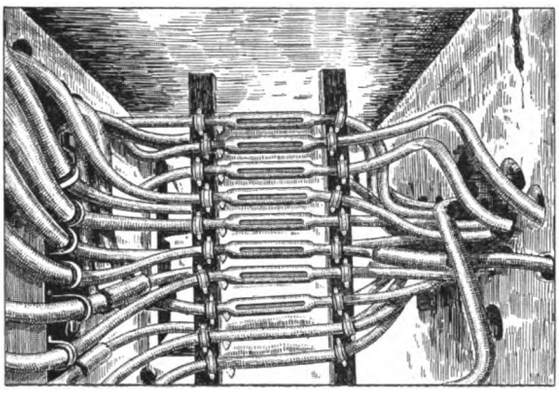


VERTICAL SECTIONS THROUGH POWER STATION AT BOILER HOUSE AND AT MACHINERY ROOM.

Digitized by Google

in the excavations, making an inside form for the concrete shells of the handholes, which are 5in. in thickness, internally plastered with cement mortar.

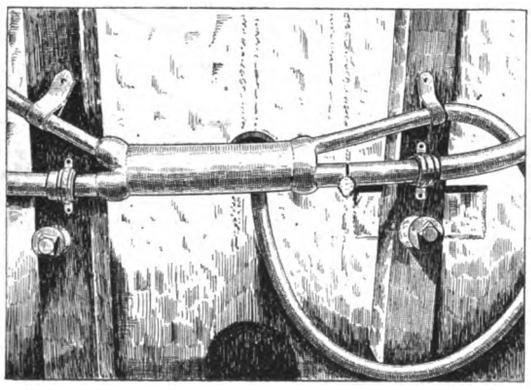
To prevent the water entering the slot from trickling down the sides and dripping over the conductor rails, which are 6in. apart, the upper flange of the slot rails in such a road must be fitted with a downwardly projecting lip, from which all water will drip off and fall between the conductor rails to the bottom of the conduit. There was, of course, no such lip on the old cable rails, and rather than replace them, bedded as they were in good asphalt paving, it was decided to rivet inch steel angle sections to them in the manner clearly shown in the sectional elevation. The angles were let down through the slot and held up against the lower face of the slot-rail head



Feeder Splices.

by a specially designed tool, and rivet holes were drilled through both at intervals of about 4ft. The holes are countersunk from the top and the rivet heads finished flush with the surface.

The old track-rail ends were badly dropped, and it was decided to bring them up by the cast-welding process. The fishplates were removed, the rail ends cleaned by hand, no power being available, for a distance of about 10in. back from the joint, and the splice-bar bolt holes in the rails were plugged, the iron plugs projecting about an inch on each side of the web so as to become bedded firmly in the casting.

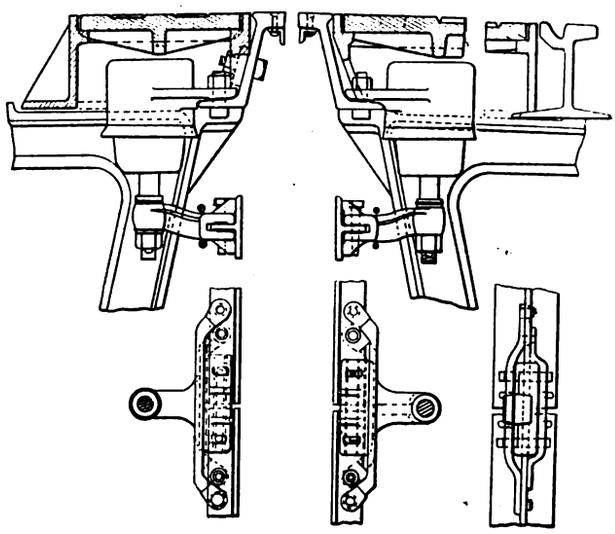


Splice of the Branches from the Feeder Cables.

Strips of iron of the rail section were driven between the abutting ends, making the joints tight. The flattened rail of each joint was shimmed up a trifle higher than the other, and the usual cast-iron mould was clamped about the hole and filled with molten iron poured from a portable furnace. The heating of the steel was found to bend the ends upward to just about a true bearing, a smooth joint being assured by finishing the surface by hand filling. The joints now ride very smoothly, but few of them being perceptible.

The conversion of the Seventh-street line, which was kept in operation by cable, except during a few hours of each night, was still more difficult. The laying of the ducts and the setting of handhole castings and insulators were done in the daytime. At night the workmen entered the conduits and secured the conductor rails to the clips of the insulating supports. The cast welding of the rail joints on this section was done several years ago. Drip angles were only put on the slot rails in the valleys.

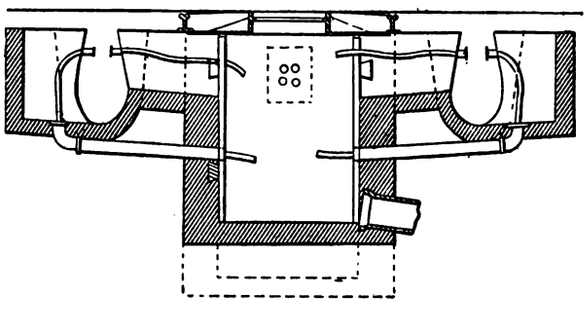
After the electric roads had been in operation about six months the Company decided to put down heavier and higher rails at the curves. Excavations were made between the yokes at all the curves, in which cast-iron chairs, weighing about 100lb. each, were set with concrete packed around them. This



Section of Track Showing Insulating Support and Bond for Conductor Rail.

work was done in the daytime, and at night after traffic was suspended the old rails were taken up, the rail seats on the yokes broken off, and the new rails put down and secured to the rail chairs. Courses of scoria block are laid on each side of the rails at the curves, the crevices between the bricks being filled with asphaltum.

As a ground return is not used, both the positive and negative feeders are insulated. There are thus 20 lead-covered cables for the 10 feeders, each with a cross-section of copper of 1,000,000 circular mils., insulated by saturated paper $\frac{3}{16}$in. in thickness, and protected by a $\frac{1}{8}$in. lead sheath. They are drawn in through manholes running across the two tracks, spaced at intervals of about 400ft. At points determined by



Draw-In Manhole, Showing Taps to the Conductor Rails and Method of Draining.

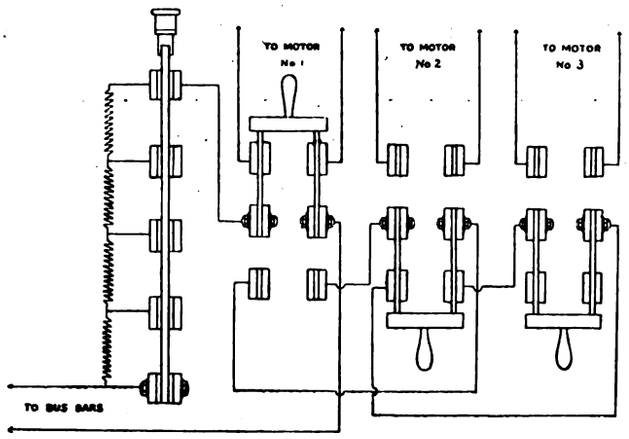
traffic conditions the feeders are tapped in the manholes with two branches from the one splice to the conductor rails, to which they are attached by clamps. Those going to the outboard rails pass down through a duct from the handholes to the manhole. One pair of cables is held in reserve as an emergency feeder, being provided with blind taps ready to be cut in at any point at any time it may be needed. In all there are about 66 miles of cables in place.

The Power House.—The work on the new power house was necessarily very much rushed, and had to be carried on almost while the drawings were being made; nevertheless, the plant evidences a surprising amount of ingenious design to overcome the difficulties involved. The work was begun about

Digitized by Google

December 1, 1897, and early in April, 1898, power was on. Old material was used to a certain extent, the good bricks of the partition walls, which had to be taken down, being used in the engine foundations, the new crane runways being made of the I-beams of the old floors, &c. The building is located on the Chesapeake and Ohio Canal. It is a long, narrow structure, which did not admit of the standard practice of placing the boilers in a row along one side of a division wall and the engines nearly in a parallel row along the other side. This building required a division midway of its length, one half being the boiler and the other half the engine room. Fortunately, solid rock was but 2ft. or 3ft. below the basement floor, so that all foundations, even to those of the auxiliary pumps, are carried clear to rock.

One of the most interesting parts of the equipment is the coal-conveying apparatus. Bituminous coal is brought directly to the plant on canal boats, holding about 120 tons each. Standing apart from the main building, towards the west, is the coal-unloading tower of steel frame construction, covered with corrugated iron sheathing. This tower has a boom projecting over the canal, by which tubs holding 1,000lb. each take the coal up from the canal boats and dump it into a receiving hopper, which, in turn, dumps it into the weighing hopper, from which it passes down into the crushing equipment. The bucket hoist and crusher are both driven by one 30 H.P. 500 volt motor. From the crusher the coal is dropped into the buckets of a pan and bucket conveyor. The driving mechanism consists of a 15 H.P. motor geared down through triple reduction gears to the heavy sprocket wheel, under which run the cables, the clamps on which fit into pockets in



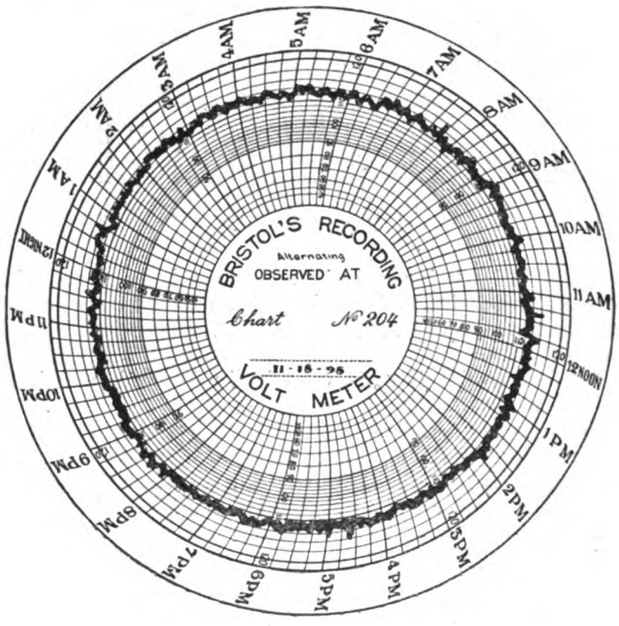
CONNECTIONS FOR THE BOOSTER STARTING RHEOSTAT.

the wheel rim, the teeth adjacent to these pockets insuring an absolute drive. The conveyor dumps the coal into bins over the boiler room.

There are four batteries of boilers in place—one battery on the west of the stack and three to the east of it. The space in front of the stack is occupied by filters, and the space to the west of the boiler room is reserved in case increased boiler power is wanted. Each battery consists of two Babcock-Wilcox boilers, each boiler being nominally of 350 H.P. The boilers are fitted with the latest type of mechanical stokers, driven by three small Westinghouse engines worm-geared to the shafts.

The piping system of this station has been the subject of unusual study, and is worked out in a very complete manner. Water for boiler feed and condensing purposes is taken from the canal through a 24-in. intake below the ice level, through two screens of half-inch mesh into a concrete settling tank or basin in the engine-room basement. From this five 8-in. pipes, with foot valves and strainers, rise and run to the five independent jet condensers of the five main units. In this way the condensers cannot interfere with or rob each other, and the choking of any one pipe does not shut down the whole plant. The exhaust of each engine passes first through a feed water heater and thence through its own jet condenser and its own independent 14-in. exhaust stack of spiral-riveted pipe. Three valve standards on the floor above at the head of each engine control respectively the valves of the steam supply, water supply, and exhaust steam supply of each condenser pump. An automatic atmospheric valve in the pipe running to each exhaust stack is fitted so that when it opens its valve stem projects upward above the floor of the engine room and stays there until forcibly pushed down by the engineer.

The feed water is handled by three pumps in one end of the boiler room, one of which, the tank pump, is arranged to lift the water from the well above mentioned to a 4,000-gallon tank over the toilet room to the rear of the boilers. A gravity pump governor controls this pump. The tank may also be supplied from the city mains through a meter at times when the canal is emptied for repairs, and an automatic float valve is installed for control under these circumstances. From the tank the water normally passes to two filters, and thence through one of two direct-acting duplex feed pumps, which in turn deliver it through any one or more of the heaters attached to the engines and then through the supplementary heater in the boiler room, thence to the feed line and to the boilers. The supplementary heater takes the exhaust of all the auxiliary engines. Finally, two injectors are installed connected with an entirely independent feed line running along the rear of the boiler steam drums.

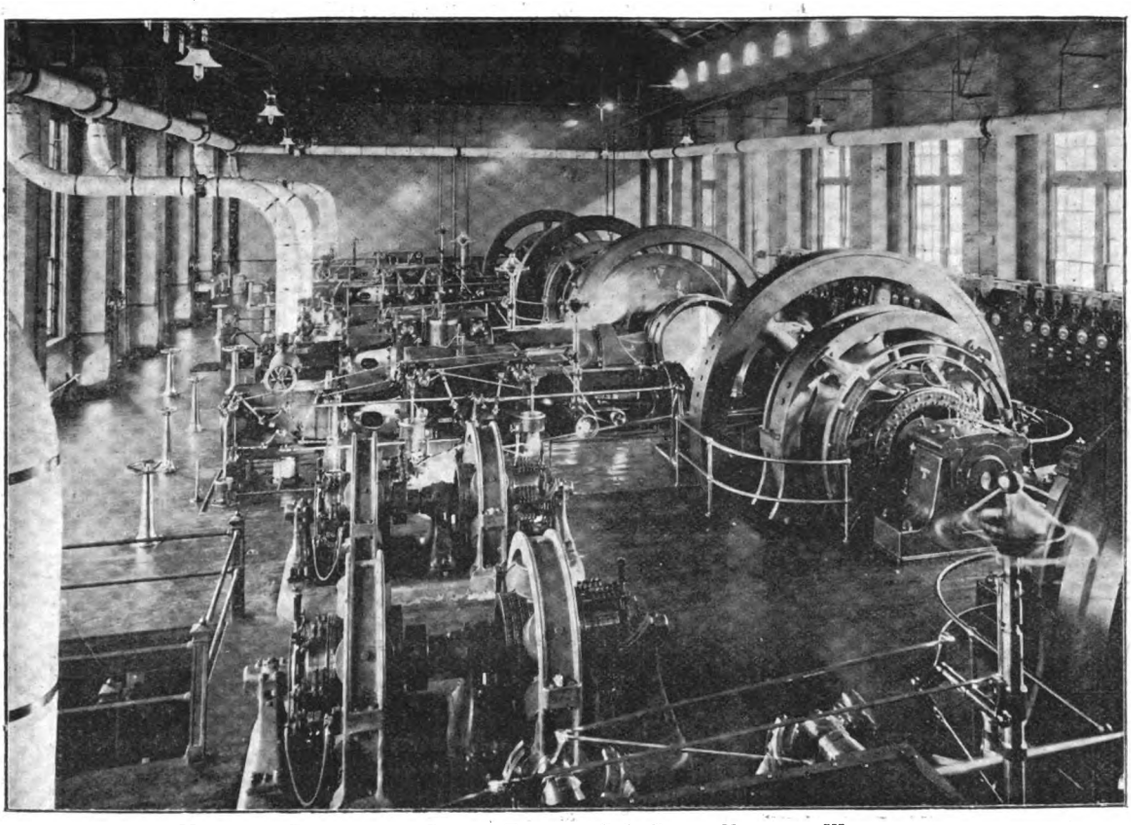


STATION PRESSURE RECORD.

The main steam pipe is run on the ring system and is all of extra heavy piping designed for 200lb. steam pressure, although the pressure at present carried is 140lb. The main header is run along one side of the boiler room and continued along the same side of the engine room and into it all the boilers feed and from it all the engines take steam. This header is 12in. in diameter, its terminals being connected around to the opposite side of the building, to a 10in. auxiliary main. These two mains are cross-connected near the division wall by an 8in. equalising main, giving a sort of figure 8 arrangement. Over the boilers the main header is supported on gas-pipe stands with ball and socket bases to allow for expansion, and at other points it is hung by adjustable rods from brackets and stayed against vibration by sliding attachments to the pilasters. Both the main header and the auxiliary main are anchored where they pass through the wall between the engine and the boiler rooms, and the expansion—which amounts to a movement of about 8in. at the extreme ends—is taken up without slip joints or copper bends. This is done by giving each boiler and engine branch a horizontal run with a vertical turn at each end, so joined that the flanges give the proper flexibility. There is a gate valve in the main header between each battery of boilers and between each engine, so that any part of the main can be cut out without shutting down more than one battery or one engine at a time.

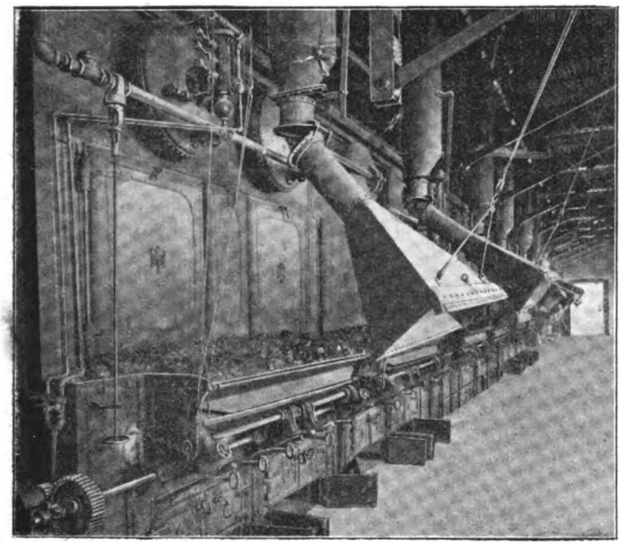
Digitized by Google

The cross or equalising main allows the steam to be fed viâ any one of several routes, thus giving a surety of operation even with simultaneous accidents to more than one part of the system. Steam for all auxiliaries is taken off from the middle of the equalising main, which it can reach by



MACHINERY ROOM OF THE CAPITAL TRACTION CO.'S POWER HOUSE, AT WASHINGTON.

either the main header or the auxiliary main. The steam is dried by two separators, one in each of the two steam mains near the points where they pass through the boiler room wall, the entrainment from these separators being returned to the boilers by gravity through the blow-off connections. There are no separators near the engines and the



INTERIOR OF THE BOILER HOUSE.

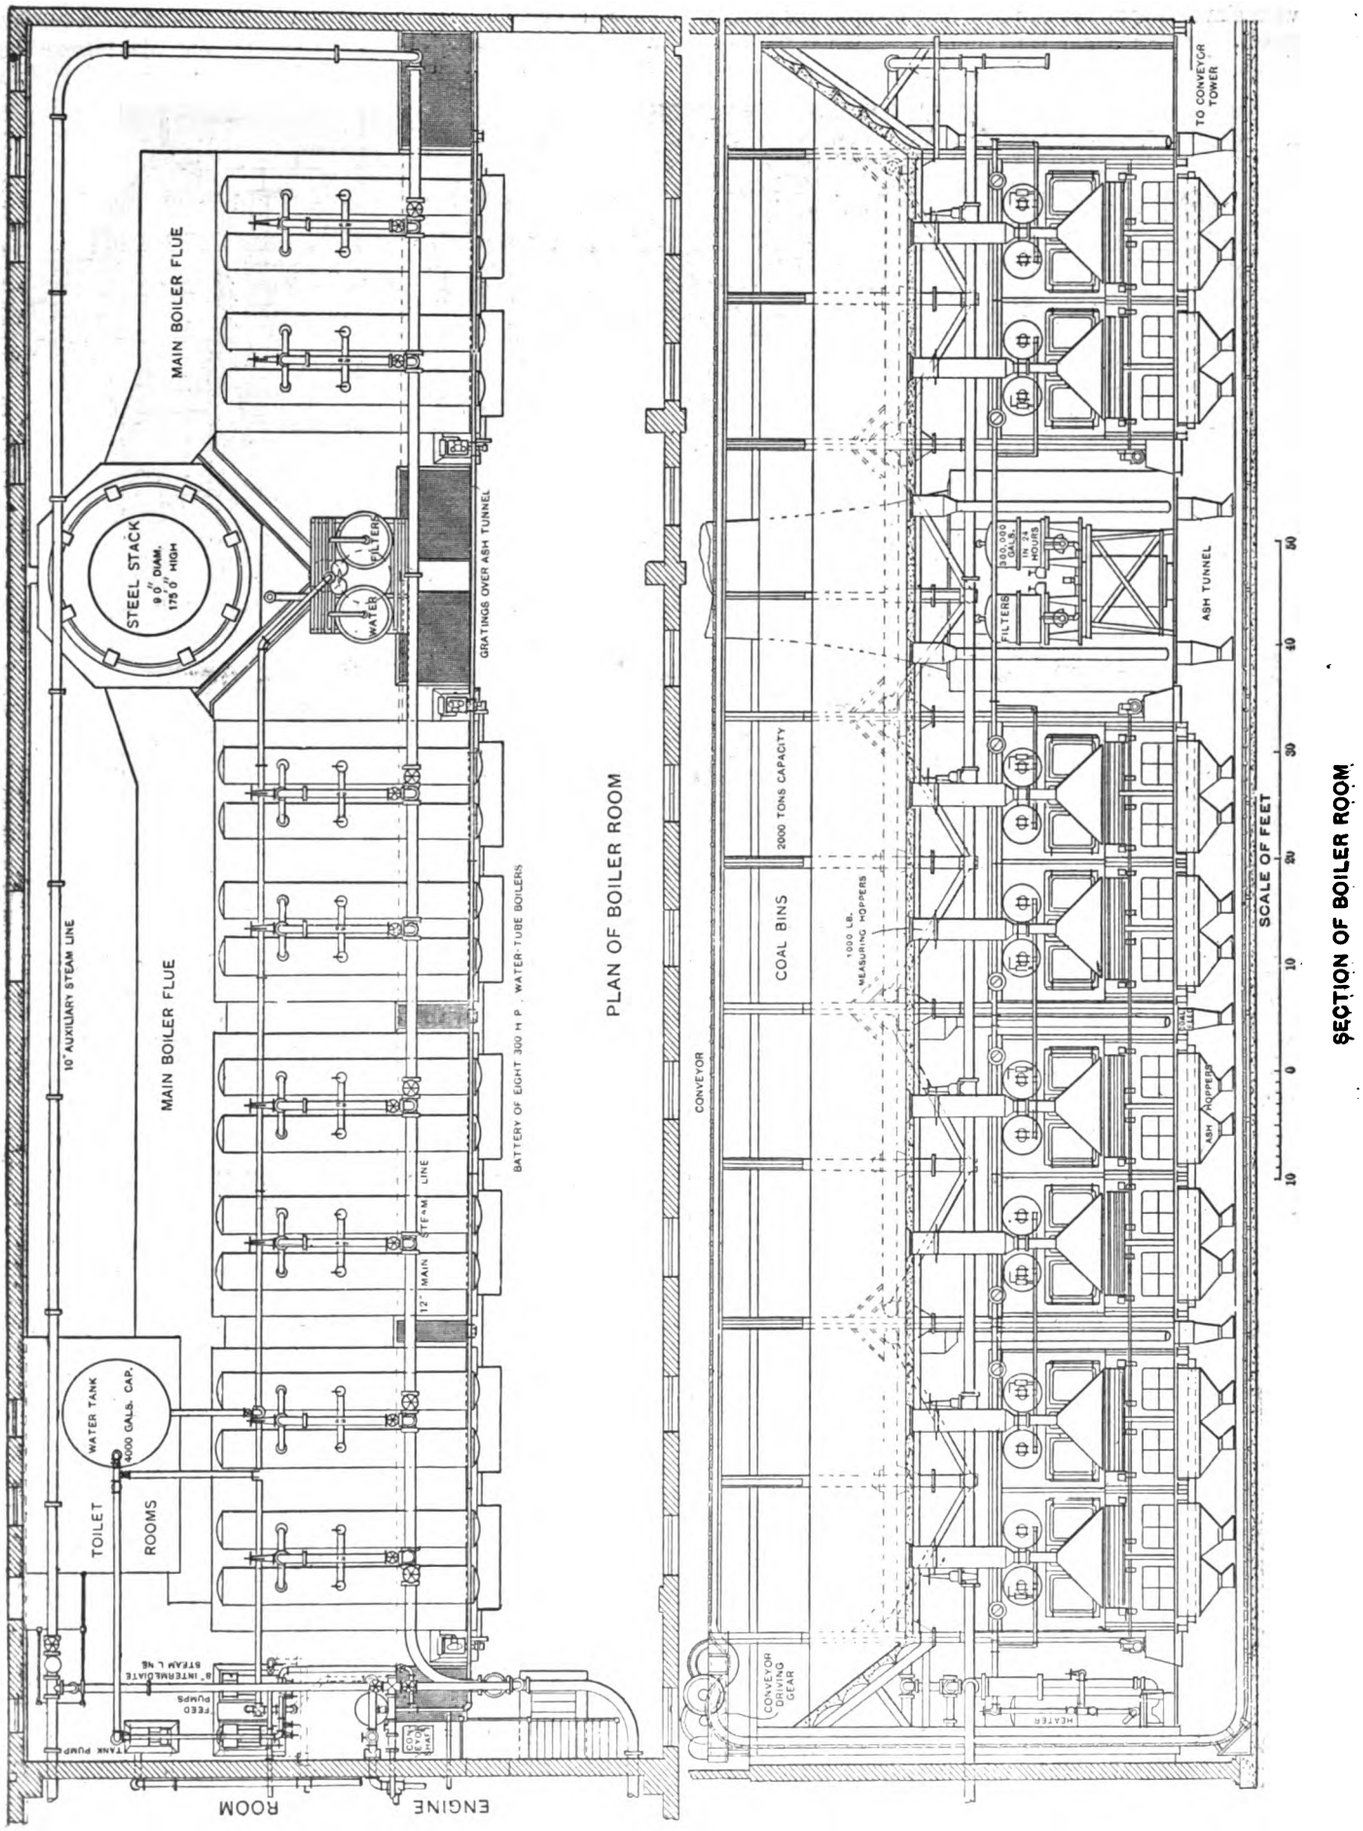
tees for the engine branches open downward, but there is absolutely no water knocking in the cylinders. The main header has no slope one way or the other, but the auxiliary main slopes from both directions toward its separator.

The main engine room is noticeable for the ample provision of light. A 15 ton hand crane spans the room. Ten enclosed arc lights are supported from the craneways on hinged gas-pipe brackets. There are five main Allis-Corliss tandem-compound 800 H.P. engines, with the standard and well-known features of this design, the 1890 frame. Four of these are arranged in right and left-hand pairs on two heavy brick foundations carried down to rock and capped with cast-iron oil pans. Each engine is coupled to a standard 600-volt generator, and fitted with a 16-ft. 25-ton cast-iron flywheel. Between these engines there are to be three motor-driven boosters, two of which are now installed, each with a capacity of 550 amperes and 180 volts, with a straight characteristic up to 100 volts when running at 600 revolutions per minute. These are 100 kilowatt 6-pole three-bearing machines with a coupling, fitted under the overhanging barrel, winding at the motor end. The dynamo ends are series wound.

The switchboard is of standard General Electric construction with a few peculiarities. The five panels at the left-hand end are standard 1,000-ampere generator panels, with current indicators; the next panel contains two totalising output instruments, one an 8,000-ammeter and the other a 5,000-ampere integrating wattmeter, and beyond these come the feeder panels, of which two are required for each feeder, one positive and one negative with throw-over switches, by which the polarity of the sections fed may be reversed when desired. This is to provide against a ground on the west rail of one section, for example, and the east rail of another, short-circuiting the 'buses. By reversing the polarity of either one of the two feeders, the two grounds can be brought on one side of the system and the same can be done with any number of grounds provided no two of them are on opposite sides of one section. On account of the 600 volts difference between adjacent feeder panels, the circuit breakers at the tops are separated by wooden barriers.

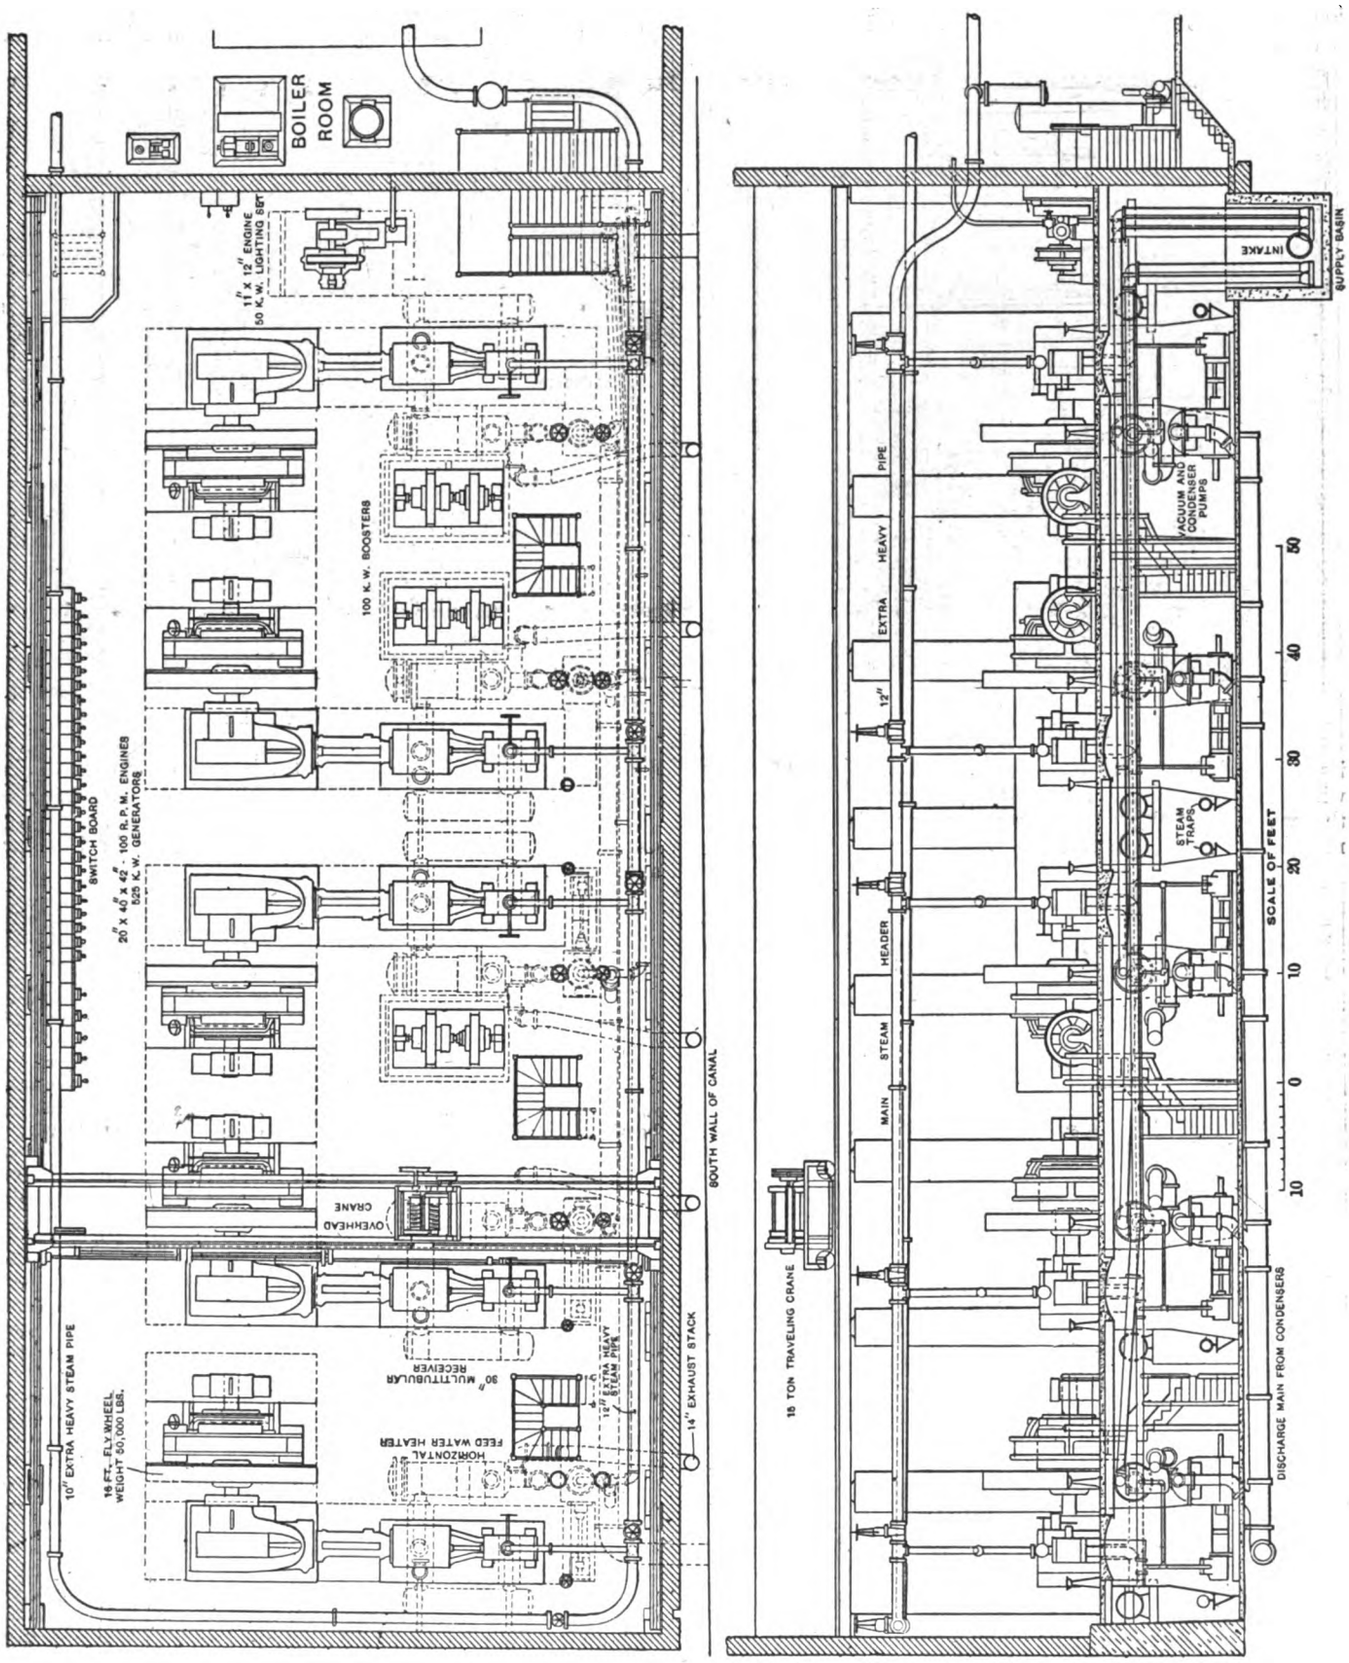
The controlling arrangements of the boosters are novel and very interesting. But one motor-starting rheostat is used for all the machines, and this is of the single-switch type, the different clips which grasp the knife blade at different positions cutting out the different sections. This is connected, in to the line feeding the various motors through a number of double-pole double-throw switches, one for each motor, connected up as shown in the diagram. Tracing out the lines, it will be seen that any switch thrown up cuts the rheostat in to

Digitized by Google



Digitized by Google

the corresponding motor, and absolutely cuts it out from any of the others. Another interesting detail is the protective device designed to cut the series-wound booster generator out when for any reason the circuit breaker of the motor opens, energised, closes the circuit of a fine wire winding on the booster-generator circuit breaker, which operates the trigger to open the breaker, and immediately thereafter opens the circuit of this same fine-wire winding, and also opens the

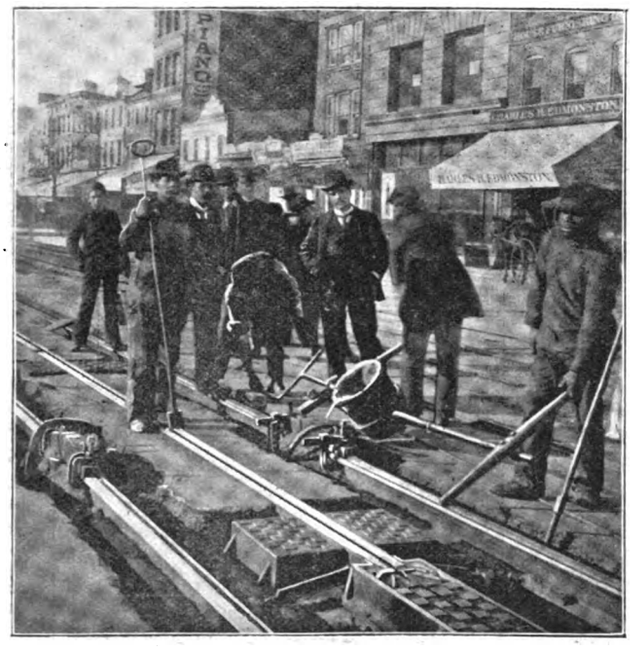


PLAN AND ELEVATION OF THE MACHINERY ROOM.

under which circumstance the generator would tend to run away as a series motor. The circuit breaker of the booster motor is provided with the ordinary tell-tale connected into a battery circuit, which in turn energises the magnet of a specially designed relay. This relay, when its magnet is battery circuit to prevent waste of battery power. This does not connect the boosted feeders over on to the 'bus-bars, but leaves them on open circuit. There are two long feeders for which the boosters are intended, the board being so arranged that each of these feeders may be thrown in series with its own

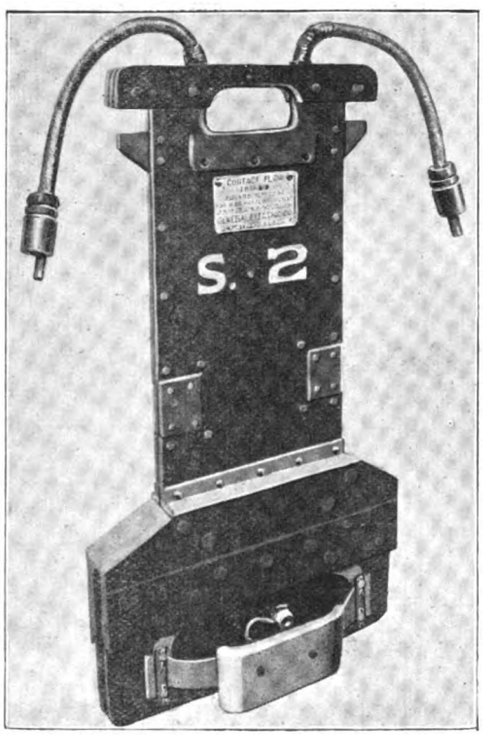
Digitized by Google

booster, the third booster being arranged to be thrown on either of the two feeders, or either feeder may be thrown directly to the 600 volt 'bus. At the right-hand end of the board, the next to the last panel is fitted with a water rheostat, which may be connected between either 'bus and ground,



CAST-WELDING THE OLD RAIL JOINTS.

its purpose being to burn out grounds on the line by a current which may be thrown on through and adjusted by means of the water rheostat. The last panel controls the auxiliary motors and 600 volt lighting lines.



COLLECTOR PLOUGH FOR THE CONDUIT SYSTEM.

Rolling Stock.—About 60 motor cars are run, and both trucks and bodies are new. Short cars with bodies only 16ft. long are used, and run with trailers. The collector plough, a view of which is shown, consists of the usual steel plate enclosing copper straps and running down through the ¾in. slot with an enlarged wooden section carrying on outward-bearing springs the cast-iron shoes. The shoes are bevelled at the ends to prevent their catching on the joints in conductor bars and on parts of the switch gear. The plough-hanger in the truck is ingeniously arranged, so that in case of derailment or a misplaced switch the plough will fall off after travelling part way across to the side frames of the truck, and

DRILLING THE SLOT RAIL FOR THE DRIP ANGLE LIPS.

drop into the conduit sufficiently to clear the motors. This prevents, in case of such an accident, the plough from becoming wedged and twisted in the slot, which requires its cutting out by cold chisels and the shutting down of the line for some time.

HIGH-SPEED ENGINES.*

BY J. H. DALES.

In applying provisions for eliminating knock in double-acting engines, the author had found that the ordinary rates of rotation could, with practical immunity from overheating, and an absolute freedom from seizure of bearings, be exceeded to the extent of 30 per cent. to 50 per cent. This had been effected by providing a close-up, and at the same time expansible, adjustment of bearing brasses, and so reducing the production of heat to only that caused by the rotation of a shaft as distinguished from the usual cause of seizure—namely, the expansive force of the metal of both journal and brasses. At moderate rates of rotation, say, 300 revolutions per minute, an audible knock took place with a $\frac{1}{500}$in. clearance in the bearings of double-acting engines, and a rise of temperature of 20°F. or 30°F., which almost always took place in practice, would expand the bearings more than that amount of clearance, and, therefore, an engine, if fitted with fixed brasses, was always liable, with little or no warning, to become overheated, and to seize in its bearings. The provisions which were made for avoiding the usual consequences of heating were very simple, and consisted of a small ram of the hydraulic pressure type, which was made to bear on the adjustable brass of a bearing. On the alternative stroke of an engine, when the working pressure was not on the adjustable brass, the ram was forced through its packing by a spring of sufficient strength to overcome the friction and the inertia of the ram and parts, and in such manner placed the adjustable brass close on its journal. This action caused a slight clearance in the ram cylinder, which was instantly filled by liquid from a reservoir which entered by a back-pressure valve. The shock of the working stroke of the engine acting upon the liquid inside the ram cylinder instantly shut the back-pressure valve and confined the liquid as a packing at the back of the ram, and so maintained the adjustment of the brass which had been made by the spring. Similar fittings were provided on all the reciprocating bearings of an engine which were usually subject to knock.

The value of close governing had been very much underrated. It could be shown that by running to within 1 per cent. or 1½ per

* Abstract of a Paper read before the Institution of Civil Engineers, January 10, 1899.

Digitized by Google

cent. total variation in the speed of an engine, an increase over ordinary results in the quantity of work could be produced, which in many cases amounted in value to more than the whole of the coal bill. The possibilities of close governing by the various types of governor in common use had been investigated, and it had been found that dead-weight loaded governors of the ordinary type, even when compensated for change of position, could not be moved by any less variation of speed than about 2 per cent. from the normal, or a total variation of 4 per cent., taking no account of any work to be performed in the way of moving throttle or expansion apparatus. Spring-load governors with angular arms pivoted, as in the former case, on plain pins, could be moved with a variation of 1½ per cent. from the normal, or a total of 3 per cent., taking no account of the performance of any governing functions. Spring-load governors, fitted in all joints with ball bearings and designed with small relative inertia and high speed, had been made to work auxiliary apparatus with as little variation of speed as 1½ per cent. total, and had governed engines within those limits.

Perfect governing could be obtained when (1st) the direction of the strains of centrifugal force were not diverted; (2nd) such strains were directly radial; (3rd) the friction and inertia of the centrifugal generating parts were reduced to a minimum; (4th) the mechanical relations of the governing parts were constant; (5th) the inertia of the centrifugal generating parts, whilst very small relatively to the centrifugal forces, were as far as possible in excess of the driven parts of the governing apparatus. These points were embodied in a fly-wheel governor dealt with, in which the load springs were arranged radially, as also were the spring-boxes and guides belonging thereto, so that the centrifugal forces caused no cross strains. The springs formed a large part of the centrifugal weights, and had a peculiar effect upon themselves which was illustrated by a diagram. The motion of the governor, in performing its functions, was transmitted to the expansion eccentric by means of a spur-wheel mounted on a sleeve which was solid with the eccentric, and was actuated by means of rack teeth formed in the spring-box slides, giving a practically constant mechanical effect in the action between the governor and the expansion eccentric. The inertia of the governor was in excess of the driven parts as about 3 to 1, while the centrifugal weights were about 2 per cent. of the total spring-load. The total average centrifugal force of the governor was about 3,000lb., and the only cross strains on the spring-box slides were those brought about by driving the cut-off eccentric, and those strains were relatively very small, as the cut-off valve was worked by a rocking shaft and twisting spindle in order to avoid the friction of a pulling spindle and the effects of the steam pressure on the same. The arrangement could be adjusted so as to govern an engine to 1 per cent. total variation throughout the whole steam range of the expansion gear, which was about ⅝ cut-off from zero, and without racing. The expansion motion was reversible with the same set of parts.

CORRESPONDENCE.

WIRELESS TELEGRAPHY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In Mr. Evershed's reply to my remarks in the discussion of his most able paper on "Telegraphy by Magnetic induction," he rather attributed to me a meaning I did not intend to convey. I did not wish to state that the difference in the energy received in the receiving circuit at Mr. Preece's Lavernock Flat Holm system, when a simple permanent current was put on the primary or transmitting circuit, and when the primary current was rapidly made and broken, was due to absorption. I am not concerned at all with the name of the phenomenon, but simply wished to indicate that, since such difference *does* exist, a better way of signalling is available, viz., by taking advantage of the stronger, but slower varying currents produced in the receiving circuit of such systems when steady currents, broken only by the signalling key, or other currents of low frequency, are sent over the transmitting circuit. A telephone, coherer, or other extremely sensitive receiver which may require a high or harmonic frequency can still be used in the receiving circuit. This is to be done (as described in my Patent Specification, No. 30,123 of 1896) by splitting up the *received* current into rapid pulsations immediately next the telephone or other receiver itself, by means of a rapid make and break applied to the receiving circuit. I use for this purpose a light, rapid, trembling bell motion, with an additional insulated contact spring moved by the vibrating armature and operating to rapidly open and close the *receiving* line circuit, without producing any current therein, care being, of course, taken to twist together the leads bringing the local current. The transmitting circuit then contains nothing but the battery or generator and signalling key, connected to the pair of earth plates. If a coherer, with its usual set of accessories, is employed as a receiver, it is placed as a shunt across an electro-magnet or induction coil, the extra currents from the latter, when the received current, however faint, is made and broken in this way, being found to actuate the coherer very effectively. Under many conditions (as, for instance, in my proposed bare wire cables, on which tests have been made) this appears to be the best way of working.

I would add that where, in any of these receiving circuits, it is desirable to operate a vibrating relay of definite rate, such as the exquisitely sensitive one designed by Mr. Evershed, this can be done by simply adjusting the rate of the local vibrator in the receiving circuit to that of the relay. Earth currents can usually be stopped by means of a condenser, which may generally be of very small capacity, and yet be sufficient to allow of the proper reception of the signalling currents. This method of working appears to extend the possible limits of this class of telegraphy.—Yours, &c.

A. C. BROWN.

LEGAL INTELLIGENCE.

Postmaster-General v. Edinburgh Town Council.

In the Edinburgh Sheriff's Court, on Tuesday, Sheriff Rutherford heard an application by the Postmaster-General for an order upon the Lord Provost, Magistrates, and Council of Edinburgh requiring them to give their consent to the placing and maintaining of a certain line or lines of underground telegraphs. The Council oppose the application on the ground that the wires were intended for the use of the National Telephone Co. as part of their undertaking, and the Council object to giving any rights in the streets to private or commercial undertakings whether applied for directly or through the medium of the Post Office.

Mr. F. T. COOPER (for the Council) held that the application was not made in good faith by the Postmaster-General for the purpose of the Post Office, but was intended to facilitate communication between one exchange of the National Company and another, to put the exchanges in connection with the trunk system of the country, which is in the control of the Postmaster-General. If consent were given they reserved their right even to interdict the Postmaster-General. The Postmaster-General had ample conduits for public telegraph and telephone purposes. If the consent sought were given, he did not see where it was to end. He admitted that the initial outlay might be the Government's, but the company would bear the cost ultimately. He did not anticipate that any expense would fall upon the Council, except the loss of valuable ground, which might be required for other purposes.

Mr. FLEMING (for the Post Office) submitted that a telephone had been declared to be a telegraph under the Telegraph Acts. In 1868 the Postmaster-General obtained the exclusive privilege to send telegraphic messages throughout the country, which meant that he had also the same privilege in regard to the telephone. He could start a telephone system anywhere by virtue of this privilege. Not being in the position to do the work himself the Postmaster-General issued licences to companies for local work, but retained the trunk wires in his own control. There was now only one telephone exchange company in the country. The wires the Post Office desired to lay down were to be trunk wires, connecting centre and centre, which privilege was the exclusive monopoly of the Postmaster-General.

The DEAN OF FACULTY (for the Council) asked where the Postmaster-General got the title to lay conduits on the private property of anybody? Why should the Post Office (and the National Telephone Co. through the Post Office) be entitled to do something which they could not do of themselves, and upon terms which they could not themselves obtain? If the National Company could not touch the streets of Edinburgh by applying to the Council, why should they be able to do so through the Post Office? He disputed that the Postmaster-General might, regardless of the prospective requirements of the city, claim the right to do so. The Council possessed an express statutory prohibition against anybody interfering with the streets.

The SOLICITOR-GENERAL (for the Post Office) said it was the fact that there had been no previous experience of an application of this kind in Scotland, but there had been a dozen in England. In this case he contended all that was required was that the consent of the Council should be asked, and if it was not given, that notice should be served upon them. It was then for the Council to state a relevant objection. In answer to the objection that this was not a Post Office purpose, he said it was quite true he did not show any connection with the Post Office, but the reason for that was easily explained. The Edinburgh Council had already permitted the Post Office to connect the Central telephone exchange with the Edinburgh post office by underground wires, and the result of that was that all the local exchanges, when they had to communicate with the

Digitized by Google

post office, had first to go through the Central exchange, and then the central exchange communicated with the post office. One of the chief causes of the unsatisfactory working of the telephone was overhead wires, which were apt to get disarranged by storms, and the Telephone Company were anxious that the wires connecting the local exchanges should be placed underground. Was it possible to represent as not being a good Post Office service that the means of allowing the public to use the trunk lines should be improved? He failed to extract any meaning from the contention that the wires were not required for Post Office purposes, because the position of the licensee was this—he was in the shoes of the Postmaster-General, with all the powers the latter had except the one power of opening the streets without special consent, but he was bound to pay the Postmaster-General 10 per cent. of everything he took. Therefore, everything the Postmaster-General did that would result or not result in increasing the income of the licensee was a Post Office purpose. If the Corporation could have said that from side to side and from top to bottom the solum was so packed with tubes and drains and pipes that they could not get another one in, that would have been a good objection ; but it was an averment that could not possibly be made. He maintained that there was no ground for the Corporation not granting its consent, and that his Lordship should grant decree in terms of the notice.

Sheriff Rutherford reserved his decision.

African Direct Telegraph Co. (Limited) v. Webb.

At the Lord Mayor's Court, on Monday, before the Recorder and a Common Jury, the African Direct Telegraph Co. sued the defendant to recover damages for breach of contract. Mr. Glyn appeared for plaintiffs, the defendant not being present or represented.

Mr. GLYN stated that on June 6, 1896, an agreement was entered into between the parties, under which defendant agreed to serve plaintiffs as an operator for a period of five years, at a salary of £72 per annum. At the end of five years the engagement was terminable by three months' notice on either side. The defendant was sent out at an increased salary to the Gold Coast, West Africa, but he left the plaintiff company's employment in June, 1898, without notice, caused loss to the plaintiffs, as they were compelled to send out another operator, and there was a claim for damages. Plaintiffs considered it necessary that where operators left their employment without notice the company should claim damages for breach of the agreement, as otherwise the whole telegraphic service must be seriously inconvenienced. In the present case the plaintiffs were obliged to send someone over from England almost at a moment's notice, and they actually incurred expenses amounting to £60. 3s. 4d.

Mr. H. E. PLANK, secretary to the plaintiff company, gave evidence in support of the claim, and stated that, in addition to paying £26 for the passage of the second operator, the plaintiffs paid £34. 3s. 4d. as his wages for a month during the passage.

The RECORDER said it was intolerable that agreements of a binding character should be broken in the manner proved by the plaintiffs, as such conduct caused the greatest possible inconvenience. He thought the plaintiff company had acted very fairly in not pressing for exemplary damages.

The jury found for the plaintiffs, and judgment was given for £60. 3s. 4d. and costs.

Stegmann v. O'Connor.

This case (reported last week) was resumed in the Queen's Bench on Tuesday. At the conclusion of the arguments of counsel their lordships intimated that they would give judgment in a few days, as the case might have to go back to the official referee.

At the Marylebone (London) Police Court, last week, Messrs. Allingham and Fennell, electrical engineers, were summoned for connecting up a supply of electric current in the area of the Hampstead Vestry without the consent of the Lighting committee of the Vestry. Mr. A. P. Johnson, solicitor to the Vestry, said defendants were electric wiring contractors, and had orders to wire the house of a resident in Lyndhurst-road, Hampstead. The act required that the fittings should be tested before the connection was made, as a safeguard against fire. An appointment was made for the test to be carried out, but defendants did not keep it, and afterwards wrote saying that they would communicate when they were ready. About three weeks later one of the Vestry officials passed the house, and saw that the connection had been made without the knowledge or consent of the Vestry, and that all the parts of the house were illuminated. There was no meter fixed, but the occupier, who was an innocent party, had arranged to pay an agreed sum. A plea of "Guilty" having been recorded, the magistrate imposed a fine of £3 and £1. 3s. costs.

At Hampstead (London) the above defendants were summoned for making a similar connection to another house in the same district without the Hampstead Vestry's sanction. When the meter fixer employed by the Vestry went to connect the electric lighting wires of the house on to the Vestry's main, he found that defendants had already made the connection. To do this they had to break open the Vestry's fuse-box, which was sealed. This temporary connection had been made for a week, and when the installation was tested it was found to be defective, and the connection was cut off. It was a very bad case, and there was danger of fire through it. By the action of the contractors the consumer of the light was also rendered liable to prosecution, but the Vestry were not taking proceedings against him. Mr. Allingham (one of the defendants) said the light had been put on for only a short time, in order to test the lamps in the house. He denied that the fuse-box was sealed. The Bench imposed a fine of £3. 3s. and £1. 3s. costs.

TRADE NOTES AND NOTICES.

Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.]

NEW BOOKS AND EDITIONS.

The following New Books and Editions can be obtained of the Booksellers or direct from the Publishing Offices, 1, 2 and 3, Salisbury-court, Fleet-street, London :—

NOW READY.

"ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS."—By J. Elton Young, M.I.E.E. The scope of the book aims at furnishing a fuller treatment of the subject, from the standpoint of the Telegraph Engineer, than it has hitherto received, whilst it endeavours to facilitate a thorough comprehension of the theory of testing as applied to electrical lines in general. The Author hopes that, besides Telegraph and Telephone Engineers, it may, perhaps, also prove of service to those in charge of cables for the transmission of light and power. The localisation of faults has been very fully investigated, including the different degrees in which the various methods are affected by the presence of a second fault or of general leakage.—*Extract from Preface.* Demy 8vo, fully illustrated. 10s. 6d., post free ; abroad 11s.

"SUBMARINE CABLE-LAYING AND REPAIRING."—By H. D. Wilkinson, M.I.E.E., &c., fully illustrated; price 12s. 6d.

"THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING."—A new work by Messrs. H. K. C. Fisher and J. C. H. Darby, with the above title, is now ready, price 6s. net; abroad, 6s. 3d. This work is intended to serve as a guide to operators already in the telegraph service, and to those who desire to enter that service. The great cable companies now insist that their operators and probationers shall pass certain examinations in electrical subjects. The book is very fully illustrated. *Second Edition now ready.*

"PRACTICAL NOTES FOR ELECTRICAL STUDENTS."—By Messrs. A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free.

"ELECTRO-CHEMISTRY."—By Dr. G. Gore. Third Edition. Price 2s., post free.

"WIRELESS TELEGRAPHY: SIGNALLING ACROSS SPACE WITHOUT WIRES BY ELECTRIC WAVES."—By Dr. O. J. Lodge, with many original illustrations. *Enlarged Edition*, 2s. 6d. net, 2s. 9d. post free.

"ELECTRIC MOTIVE POWER," by Albion T. Snell, contains the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d., post free ; abroad, 11s.

"LABORATORY NOTES AND FORMS."—With the above title we have ready the New Edition of a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators and Students. The object of this series is the saving of the time of the Teacher and his Assistants, and to serve as a record of the work done by the Student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen net ; in sets of any three, 1s. net ; or the set of Twenty (Elementary or Advanced) Exercises can be obtained, price 5s. 6d. net. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. net ; or in handy portfolio, price 12s. net ; or bound in strong cloth case, price 12s. 6d. net. Strong portfolios can be had, price 1s. each.

NOW READY.—The cheaper edition of Dr. J. A. Fleming's "Electrical Laboratory Notes and Forms." These cheaper Forms have been prepared for the use of students and teachers at the Polytechnic and other science classes throughout the country. The demand for the original set of these Notes and Forms has led to a request for a cheaper set for use at the day and evening classes at many of the technical institutes. These new Forms, which differ only from the higher-priced set in being printed on smaller and cheaper paper and with less space for tabulated records, are issued at half the price of the original set.

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready. Price 7s. 6d. ; abroad, 8s.

"THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS."—Edited and enlarged by W. Worby Beaumont. Price 3s. 6d., post free.

"THE ART OF ELECTROLYTIC SEPARATION OF METALS."—A second issue of Dr. Gore's book is now ready, price 10s. 6d., post free.

"THE MANUFACTURE OF ELECTRIC LIGHT CARBONS."—A Practical Guide to the establishment of a Carbon Manufactory. Fully illustrated. price 1s. 6d. ; post free, 1s. 9d.

"THE BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH, 1896-97." A valuable, up-to-date compilation. Being an attempt to classify the data relating to X-Ray work. This work contains a quantity of general as well as special information bearing upon the whole subject of electrical discharge research. Price 5s., post free ; abroad, 5s. 3d.

"LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS."—By F. C. Raphael. Price 5s., post free ; abroad, 5s. 6d. Prospectus on application.

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book, by Messrs. W. Geipel and H. M. Kilgour ; price 7s. 6d. ; by post, 7s. 9d. ; abroad, 8s. A fine large paper edition with wide margins for notes can also be supplied. Price 12s. 6d. ; post free, 13s. ; abroad, 13s. 6d. *New Edition in the press.*

"THE ALTERNATE CURRENT TRANSFORMER," Vol. I.—By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. *New Edition.* Price 12s. 6d., post free. Vol. II., price 12s. 6d. post free, is also ready.

"ELECTROMAGNETIC THEORY."—By Oliver Heaviside. Vol. I., price 12s. 6d. ; post free, 13s.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free.

"THE ELECTRICIAN" PRIMERS.—In Two Volumes. Vol. I., Theory. Vol. II., Practice. Price, stout paper cover, 2s. 2d. each, post free ; cloth, 2s. 9d. Single Primers, 3d. each, post free.

Digitized by Google

"ARMATURE WINDINGS OF ELECTRIC MACHINES."—By H. F. Parshall and H. M. Hobart. This work has been compiled from notes made by Mr. Parshall in his capacity as Chief Designing Engineer of the Edison and General Electric Companies of America, and is intended to serve as a working treatise on dynamo design. Large 4to, 370 pages, 140 full-page illustrations and 65 full-page tables, 30s., post free.

"DRUM ARMATURES AND COMMUTATORS," by Mr. F. Marten Weymouth, also ready. Price 7s. 6d.; abroad, 8s. Prospectus on application.

"THE POTENTIOMETER AND ITS ADJUNCTS": A Universal System of Electrical Measurement.—By W. C. Fisher. Fully illustrated. Price 6s., post free; abroad, 6s. 6d. Digest post free.

"MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY."—By E. Tremlett Carter, C.E., M.I.E.E. Price 12s. 6d., post free; abroad 13s. 6d. Prospectus post free.

IN THE PRESS.

"THE ELECTRIC ARC."—By Mrs. Ayrton.

"THE MANUFACTURE OF CARBONS FOR ALL ELECTRICAL PURPOSES."—By Francis Jehl.

"ELECTROMAGNETIC THEORY."—By Oliver Heaviside. Vol. II.

"SECONDARY BATTERIES, THEIR DESIGN AND MANUFACTURE."—By E. J. Wade.

"PRIMARY BATTERIES: THEIR CONSTRUCTION AND USE."—By W. R. Cooper.

"PRACTICAL TELEPHONY."—By Dane Sinclair and F. C. Raphael.

"'THE ELECTRICIAN' WIREMAN'S POCKET-BOOK."

"The Electrician" Electrical Trades' Directory and Handbook.—An important announcement in connection with the 1899 issue of the "Big Blue Book" will be found in an advertisement on another page of the present issue, to which our readers will please refer.

TENDERS INVITED.

The *Leyton* District Council invite tenders for a motor generator and the necessary switch gear. Specifications, conditions, &c., can be obtained from the electrical engineer (Mr. H. Collings Bishop), Cathall-road, Leytonstone. An advertisement contains additional particulars, and tenders must be sent in to the clerk to the council (Mr. R. Vincent), Town Hall, Leyton, by Monday, Feb. 6.

The Corporation of *West Hartlepool* invite tenders for feeders, mains, arc light leads and road work. Further particulars are given in an advertisement, and copies of specifications, forms of tender, &c., can be obtained from the town clerk, Mr. Higson Simpson. Specifications and drawings can be seen at, but not obtained from, the offices of Prof. Alex. B. W. Kennedy, 17, Victoria-street, London, S.W. Tenders to Mr Simpson, by Monday, the 13th Feb.

The Gas committee of the *Nelson* Corporation invite tenders for the supply and erection of the following plant:—(*a*) steam dynamo, ejector condensers, &c., (*b*) switchboard, (*c*) alterations to accumulators, (*d*) overhead crane. Additional particulars are given in an advertisement, and plans, specifications, &c., may be obtained at the office of the engineer (Mr. Wm. Foster). Tenders must be sent to the town clerk (Mr. R. M. Prescott), Town Hall, Nelson, not later than noon on Tuesday, Feb. 14.

As announced in an advertisement, the Electricity committee of the *Belfast* Corporation invite tenders for the supply of the following:—Cast iron pipes, cast iron frames and covers, earthenware conduits, insulated cable, and Lancashire boilers. Specifications and conditions of contract may be obtained from Mr. Victor A. H. M'Cowen, city electrical engineer. Tenders must be lodged with the town clerk (Sir Samuel Black), City Hall, Belfast, by Thursday, Feb. 2.

The *Glasgow* Corporation invite tenders for the reconstruction of the tramways in Crown-street and Cathcart-road. Specifications, with forms of tender, can be obtained on application to the general manager (Mr. John Young), 88, Renfield-street, Glasgow, and tenders must be lodged with the town clerk (Sir J. D. Marwick), City Chambers, Glasgow, by 10 a.m. of Monday, 6th prox. Further particulars are set out in an advertisement.

As announced in our advertisement columns, the Corporation of *Harwich* invite offers for the transfer of their provisional order. Tenders must be sent in by May 17 next to the town clerk (Mr. A. J. H. Ward), Harwich.

The governors of the District Asylum of *Enniscorthy* (Ireland) invite tenders for the installation of electric tell-tale clocks. Particulars can be had from the resident medical superintendent, and tenders must be sent in by the 8th prox. See advertisement.

The Corporation of *Lowestoft* invite tenders for the supply and erection of the following plant:—(*a*) boilers and fittings, economisers, feed pumps, &c.; (*b*) pipe work, &c., for engine and boiler house; (*c*) steam dynamos and motor boosters; (*d*) storage batteries; (*e*) main switchboard and connections; (*f*) overhead travelling crane; (*g*) underground mains and conduits, road work, &c.; (*h*) arc lamps and posts; (*i*) station lighting. Tenders to Town Clerk, 115, High-street, Lowestoft, by noon, Feb. 6.

The *Buxton* District Council invite tenders for the supply of feeders, mains and arc light heads. Tenders to Mr. Josiah Taylor, Town Hall, Buxton, by Monday, Feb. 6.

The *Burton-on-Trent* Corporation invite tenders for the supply and erection of three steel Lancashire boilers at the electric light Tenders to the town clerk (Mr. T. N. Whitehead) by 10 a.m., 28th inst.

The *London* County Council invite tenders for four continuous-current dynamos, one motor generator, two switch-boards with switches, measuring instruments and other work required for the proposed Victoria Embankment electric generating station. Tenders to Mr. C. J. Stewart, County Hall, Spring-gardens, S.W., by 10 a.m. Jan. 31.

Tenders are invited for the wiring and fitting of the library premises, Whimple-street, *Plymouth*. Tenders by Feb. 8 to the borough electrical engineer East-street, Plymouth.

The *Edinburgh* Town Council invite tenders for iron and steel work at the M'Donald-road electricity station. Tenders to the town clerk by Feb. 3.

The *Fulham* (London) Vestry require tenders for electric motors for driving pumps. Tenders to the clerk by Feb. 8.

The *Kingston-on-Thames* Guardians invite tenders for private telephone communication between the various workhouse buildings. Tenders to clerk, Union offices, Kingston-on-Thames, by Feb. 14.

The municipal authorities of *San Severa* (Italy) require tenders for the electric lighting of the town. Tenders by Feb. 25 to el Municipio de San Severa (Foggia), Italy.

The *Austrian* Post and Telegraph Authorities require tenders for the supply of telegraph and telephone materials, including 950 tons of wire, required during 1899. Tenders to die K. K. Post Oekonomie Verwaltung, Vienna.

TENDERS RECEIVED AND ACCEPTED.

The Tudor Accumulator Co. has received an order for a battery having a capacity of 490 kilowatt hours, from the City and South London Railway Co.

The Watford Corporation have accepted the tender of the Reason Manufacturing Co. for cut-outs, and that of Messrs. Venner and Co. for electricity meters (Hookham).

The Exeter City Council have placed an order with Messrs. Mather and Platt for a 30-kilowatt dynamo, at £686.

APPOINTMENTS VACANT AND FILLED.

The Lee District Board of Works require for one year the services of a consulting electrical engineer. Remuneration £100. Applications by 3 p.m. of Wednesday, Feb. 8, to the clerk to the Board (Mr. George Whale), Old Charlton. See advertisement.

The Torquay Corporation require a mains electrician for their electricity department. Applications must be sent in by Saturday, 28th inst., to the Corporation electrical engineer (Mr. P. Storey), Electricity Works, Torquay. See advertisement.

The Tramways committee of the Manchester Corporation require an assistant tramway engineer. An advertisement contains additional particulars, and applications must be sent to the chairman of the committee, Town Hall, Manchester, by Saturday, Feb. 4.

The Littleborough District Council require a consulting electrical engineer. Applications to the clerk to the Council by Feb. 14.

The Governors of the Paisley Technical School require a Principal. Salary £300 per annum. Applications to the Secretary by Feb. 13.

The St. Ann's District Council received 53 applications for the position of electrical engineer, and the Electric Lighting committee reduced this number to three, viz.:—Messrs. J. Pilling (chief assistant at the Bolton Electricity Works), R. Birkett (chief assistant at Burnley), and Mr. Tiddeman (engineer to the Pontypool Electric Lighting Co.). Mr. Tiddeman was ultimately selected.

Mr. C. M. Johnston has been appointed borough electrical engineer at Shrewsbury. Mr. Johnston has been for some time electrical engineer to the Lancaster Corporation.

BUSINESS NOTICE.

The British Aron Meter Co. notify that the company's business, having been acquired by the Aron Electricity Meter (Limited), all debts due to or owing by the former company will be received and discharged by the latter.

Messrs. John Drury, Frederick Drury and James Francis Drury (trading as Drury Bros.), electric bell founders, &c., Stock Orchard-street, Holloway, London, N., have dissolved partnership. Debts by J. and J. F. Drury, who continue under the old title.

Mr. W. H. Walton, late electrical engineer to the Drapers' Company, having joined the firm of Newsome, Pinching and Co., the style of the firm has been altered to Newsome, Pinching and Walton, 1, Crutched-friars, London, E.C.

Digitized by Google

Holophane (Limited) has removed to Wardrobe Chambers, 146, Queen Victoria-street, London, E.C.

The address of the Institution of Mechanical Engineers will in future be Storey's Gate, St. James's Park, London, S.W.

BANKRUPTCIES, LIQUIDATIONS, &c.

A meeting of the shareholders of the Fowler, Lancaster Co. (Limited) will be held at Albert Works, Graham-street, Birmingham, on Feb. 20, to receive an account of the winding-up. Mr. W. Hands is liquidator.

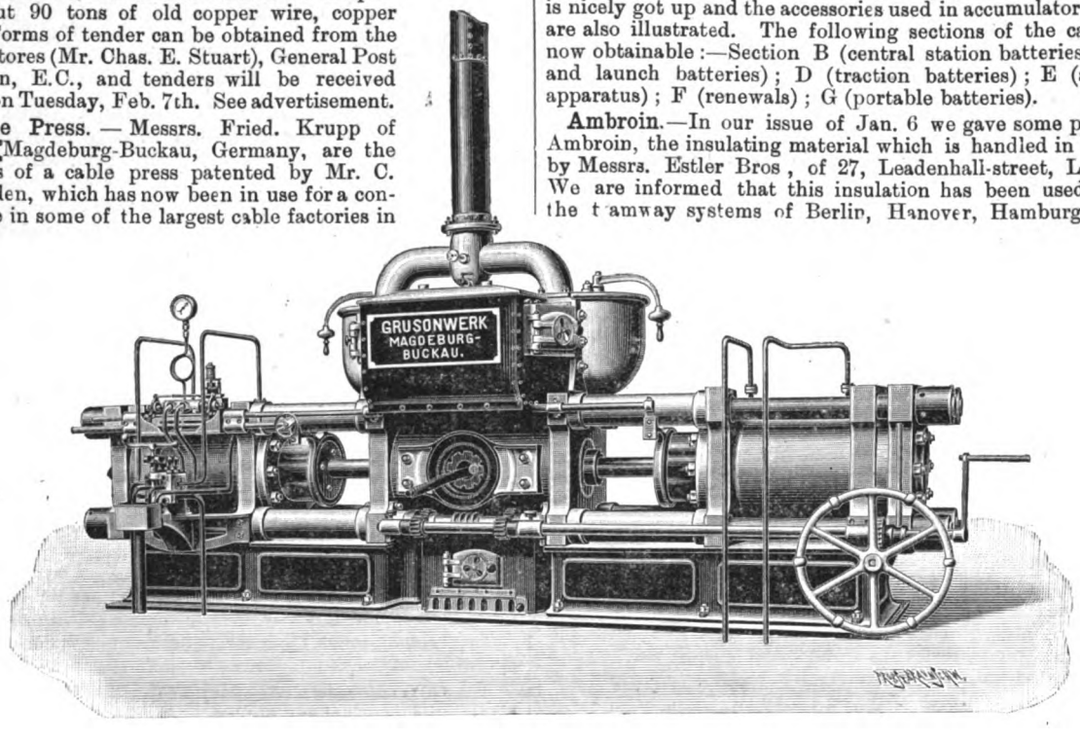
The proceedings at the two meetings of creditors of Messrs. L. V. Riley and Co. have been previously reported. Since the last meeting Mr. Seagrave, accountant, 31, Selby-road, Anerley, acting for his client and the creditors, has found funds enabling him to offer a composition of 7s. 6d. in the £, which has been accepted by the creditors in many instances.

The creditors of the London and Hampstead Battery Co., Limited, (in liquidation) must send particulars of their claims by March 1 to Mr. H. P. Spottiswoode, Donington House, Norfolk-street, London, W.C.

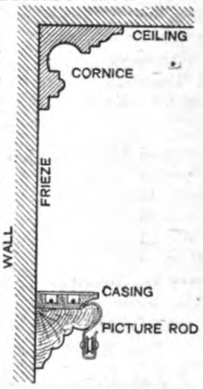
For Sale.—As announced in an advertisement, Messrs. Wheatley Kirk, Price and Goulty, Albert Chambers, Albert-square, Manchester, have for disposal electric lighting plant with a capacity of 500 16 c.p. lights.

The Postmaster-General invites tenders for the purchase of about 90 tons of old copper wire, copper plates, &c. Forms of tender can be obtained from the controller of stores (Mr. Chas. E. Stuart), General Post Office, London, E.C., and tenders will be received until 10 a.m. on Tuesday, Feb. 7th. See advertisement.

Lead Cable Press. — Messrs. Fried. Krupp of Grusonwerk, Magdeburg-Buckau, Germany, are the manufacturers of a cable press patented by Mr. C. Huber, of Baden, which has now been in use for a considerable time in some of the largest cable factories in this country and on the Continent, and which is claimed to have given satisfactory results. This press differs in many points from others on the market. It is provided with two hydraulic cylinders which work opposite one another and between which is placed the receiver containing the lead charge. Two steel rams attached to the pistons of the hydraulic cylinders pass into the bore of the receiver; on moving forward, these press the lead charge towards the matrix. The cable to be covered enters the press at one side, passes through the matrix placed in the centre of the receiver, and leaves the press on the other side. As the lead is forced towards the receiver from both ends, it is necessary that the movement of the rams shall be absolutely uniform, and this result has been obtained by means of an arrangement which regulates the velocity of the rams automatically, by altering the size of the opening, admitting water to the cylinder of that piston which is moving too fast and enlarging the opening of the other cylinder. This arrangement assures the pressure on the lead charge being perfectly uniform. An advantage claimed for this type of press is the adjusting arrangement of the matrix, by means of which a casing of absolutely uniform thickness can be turned out. By means of this arrangement the thickness of the lead casing can be made true to any fraction of a millimetre for a cable of any length. The hollow mandrels through which the cables are passed, as well as the matrices, can be quickly and easily changed. The press is made for cables from 3mm. to 60mm. in diameter. If the arrangement for centralising the cables is dispensed with, cables up to 95mm. in diameter may be covered. The melting pot placed above the receiver may be heated by coal or oil. All parts are readily accessible. The hydraulic cylinders are made of cast steel with copper lining, the rams are of chilled cast iron, the receiver of special forged Krupp steel. Messrs. Krupp's representative in this country is Mr. W. Stamm, 62, Cannon-street, London, E.C.



Combined Electric Wire Casing and Picture Rod.—The accompanying illustration shows a patent combined electric wire casing and picture rod, manufactured by Messrs. Skegg and Co., of 231, Oldfield-road, Salford, Manchester, for which we understand there is considerable demand where bracket lighting is required. The casing, as shown, is fixed upon the wall below the cornice to form a frieze, and leaves the wires easy of access. We are informed by Messrs. Skegg and Co. that this combined casing has been approved by the Phœnix Fire Office. A moulding hook or picture-holder is manufactured by the same firm, and is shown in the illustration attached to the picture rod. It will be seen that the complete arrangement is very effective and simple.



Chloride Batteries.—The Chloride Electrical Storage Syndicate (Limited) have now completed Section A of their complete catalogue, this section dealing with lighting batteries. The catalogue is nicely got up and the accessories used in accumulator installation are also illustrated. The following sections of the catalogue are now obtainable:—Section B (central station batteries); C (yacht and launch batteries); D (traction batteries); E (accumulator apparatus); F (renewals); G (portable batteries).

Ambroin.—In our issue of Jan. 6 we gave some particulars of Ambroin, the insulating material which is handled in this country by Messrs. Estler Bros, of 27, Leadenhall-street, London, E.C. We are informed that this insulation has been used largely on the tramway systems of Berlin, Hanover, Hamburg, Augsburg, Czernowitz, Leghorn, Nîmes, &c., and in smaller quantities on many other lines, including some in this country.

Electric Mining Machinery—Messrs. John Davis and Son have just issued a comprehensive catalogue of electric mining plant, apparatus and accessories. Attention is called to the considerable advance which has taken place in the design and construction of machines for the economic working of mines, particularly in the use of armoured concentric cables, more substantial switching and regulating apparatus, and the introduction of junction boxes to avoid the use of jointing wires. A large variety of haulage and pumping plant, motors, protector fittings, &c., is included in the new list.

Fire.—We are glad to announce that the fire which occurred on the premises of the General Electric Co. (Limited), 69-71, Queen Victoria-street, London, E.C., on Friday last, and which at one time promised to be serious, was extinguished by the brigade in less than an hour, enabling the company to continue their business as usual.

Roentgen Rays.—Mr. Geo. Stegmann has just issued an illustrated pamphlet and price list of Roentgen ray apparatus, for which he is agent in this country. A fully-equipped Roentgen laboratory is kept up at Mr. Stegmann's premises, 45, St. John's-hill, Clapham Junction, S.W.

"Engineering Times."—We have to acknowledge receipt of No. 2 of the "Engineering Times," a well-got-up monthly engi-

Digitized by Google

neering magazine, which claims to be "every bit English." Both the first and second numbers of this magazine have been very creditable productions, and there should be room for such a publication, if the high character of the early issues is maintained.

Labour Protection Association.—Any of our readers seeking information concerning the Labour Protection Association and its past year's work can obtain copies of the second annual report of the Association, and a pamphlet, entitled "The Law Relating to Picketing," as laid down by recent judgments, together with other information, at the offices, 7, Victoria-street, London, S.W. The report states that the Association has rendered good service in a number of strikes and labour disputes during the past year.

The Past Year.—Messrs. Willans and Robinson (Limited) again report a very prosperous year for 1898, the orders booked having amounted to over 53,700 H.P.. There were several noticeable features in the year's trade. The first is the great extension which is taking place in municipal and public company electricity stations, over 41,000 H P. of the company's output being for this class of work. Among the more important orders were the following :—

Liverpool Corporation	10,000	H.P.
Edinburgh Corporation	7,920	,,
Nottingham Corporation	3,565	,,
Brighton Corporation	1,650	,,
Chelsea Electricity Supply Co.	1,400	,,
Bristol Corporation	1,400	,,
Norwich Electricity Co.	1,300	,,
Hampstead Vestry	1,150	,,
St. Helens Corporation	1,080	,,
Westminster Electric Supply Corporation	1,080	,,

Repeat orders amounted to 43,900 H.P., and afford striking evidence, not only of the prosperity of the various undertakings, but also of continued confidence in the Willans engine. The shops have, in fact, been nearly filled with work for old customers. This, of course, resulted in many new orders being lost, on account of the impossibility of giving delivery. A third characteristic of the year's orders was the increase in the size of the units ordered. Until comparatively recently, 350 H.P. was the most usual size employed in lighting stations, and although some few of larger size were ordered, it was not until 1898 that the custom became general. During the year just ended the company has received orders for 13 engines of 1,200 H.P., two of 825, eleven of 700, six of 575, three of 450, besides some 45 ranging between 250 and 350 H.P. The tendency seems to be still upwards, as there are many inquiries for still larger sizes. Electric lighting continues to be the principal employment of the engines, orders for this work amounting to 36,700 H.P. ; but electric traction is now beginning to be of great importance also, and 14,000 H.P. were booked for this purpose, the principal customers being :—

Liverpool Corporation	10,000	H.P.
Bradford Corporation	1,400	,,
St. Helens Corporation	1,080	,,
City and South London Railway Co.	1,150	,,

The company have been making large additions to their plant to meet increasing business, and are now in a position to deal with very large quantities of work.

Exports of Electrical Apparatus and Material.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from Jan. 18 to Jan. 24, with the ports of destination :—

Argentina—Buenos Ayres, £482 (telegraph material). ***Australasia***—Auckland, £223 ; Invercargill, £56 ; Lyttelton, £32 ; Melbourne, £145 ; Sydney, £81 ; Wellington, £1,649 (including £909 telegraph material). *Belgium*—Ostend, £5. *Canada*—Montreal, £11. *Ceylon*—Colombo, £69. *China*—Shanghai, £81. *Denmark*—Copenhagen, £192 (including £178 telegraph cable) ; Kolding, £259 (telegraph cable) ; Odense, £28 (telegraph material). *Eyypt*—Alexandria, £55. *Germany*—Hamburg, £110 (telegraph material). *Holland*—Amsterdam, £125 ; Flushing, £11. *India*—Calcutta, £1,698. *Japan*—Yokohama, £740. *Madeira*, £15. *Norway*—Christiania, £100. *Russia*—Reval, £66. *South Africa*—Cape Town, £845 ; Delagoa Bay, £279 ; Durban, £166 (including £68 telegraph material) ; East London, £1,268 ; Port Elizabeth, £1,416. *Straits Settlements*—Singapore, £115. *Sweden*—Gothenburg, £148 ; Stockholm, £533 (telegraph material). *Turkey*—Constantinople, £195 (telegraph cable). Total £11,198, against £15,321 in the corresponding week last year (Jan. 20 to Jan. 26).

MUNICIPAL, FOREIGN AND GENERAL NOTES.

Bradford.—Mr. A. H. Gibbings has presented a report in which he states that, owing to the continued increase in the demand for current, considerable extensions of the plant and mains will have to be made during the present year. The Committee have already placed orders for two 300 H P. sets, which it is expected will be delivered by the middle of September, but in order to meet all demands Mr. Gibbings advises that two additional 600 H P. sets should be ordered. The following is a summary of the work it is proposed should be carried out during 1899 :—

Machinery : Two 300 H.P. engines and dynamos, £4 500 ; two switchboards, £250 ; two condensing plants, £3,500 ; one motor generator for balancing, £800 ; one induced draught boiler, £1,800 ; one grinding machine for commutator, £50 ; motors and gearing for travelling crane, £150 ; two feed water heaters, £250 ; one feed pump, electrical (new works), £150 ; one lathe, £200 ; one drilling machine, £90 ; one shaping machine, £60 ; one screwing machine for pipes, £20 ; one feed pump, electrical (old works), £120. *Condensing reservoirs :* Extensions of existing condensing reservoirs for increased load at new works, estimated cost £3,000. *Cables :* For ordinary extensions to various districts, £10,000. *Batteries :* One additional battery of 1,500 ampere-hours capacity, to give 250 volts when discharged 50 per cent. £2,000 ; switchboard and connections for above, £250. *Buildings :* Additions to Bolton-road Works : one new floor in present battery room (principally of wood), £150 ; one new floor in old boiler shed, £200. Total cost, £27,540.

Mr. Gibbings further advises that the question of the extension of the electricity supply station buildings be considered, as when the additional machinery is put down there will be no further room for extensions.

Barnsley.—The Local Government Board has sanctioned the borrowing of £25,000 for electric lighting purposes.

Cable to Honolulu.—The House Commerce committee of the United States Parliament has reported in favour of a bill granting a charter to the Pacific Cable Co. to lay a cable from San Francisco to Honolulu. The bill proposes that the United States Government shall pay the company an annual subsidy of $100,000 for 20 years.

Croydon.—The County Council are extending the arc lighting. Seventy-nine arcs are to be erected at once, to be eventually increased to 100. £22,000 is to be borrowed for carrying out this work.

Depot Lighting.—The Midland Railway Co. have recently made a clearance of a number of ramshackle tenement buildings in Pancras-road, London, N., and, upon the site, have erected one of the most imposing coal depôts in the world. The depôt is on two levels, the lower of which has to be always artificially lighted. In order to effectively illuminate a building which covers an area of some 20,000 square yards, the company have erected what is likely to develop into the largest electricity generating station for railway purposes in the country. The Midland Co. has, from the first, been foremost in the use of electricity, wherever possible, at its various termini, depôts, and similar centres of railway activity, and the policy has been adopted to the full in connection with the arrangements made at the newest of the company's depôts. The new generating station is situated at Kentish Town, and the plant installed is intended to supersede the isolated plants at the Midland Hotel, St. Pancras, and at the Somers Town goods depot, at the latter of which current for lighting the St. Pancras passenger and goods station and the Somers Town goods depôt is generated. The plant at Kentish Town consists of four 300 H.P. Lancashire boilers, duplicate pumps, economiser, and exhaust feed heater. In the engine room are three Parker 200kw. steam dynamos coupled to Willans engines. Two exciters with a set of accumulator cells and the usual switchboard equipments complete the present plant. Space is available for extensions, and the offices comprise workshop, messroom, store room and residential engineer's office. The continuous-current system is adopted, as current for both power and lighing is required. The current is generated at from 2,000 to 2,300 volts, and conducted by armoured concentric lead-covered cables. The transformer rooms are situate at Kentish Town station (now in hand), St. Pancras goods station, and St. Pancras passenger station. The cables are in duplicate, and are chiefly underground with railway sleepers placed over them for protection from platelayers' picks. The installation will also be utilised to operate a large fan for the better ventilation of the Midland portion of the "Underground" connection of the railway ; and traversers and cranes for the new locomotion shed and works, which are about to be built. Although, when designed, the generating plant was intended to provide for a spare unit, the many applications for lighting and power already indicated will practically absorb the entire capacity, and additions are already in contemplation. At present 400 arcs and nearly 2,000 incandescents are in operation.

Dorking.—Mr. W. H. Trentham has been appointed consulting electrical engineer to the Council.

Electric Power Schemes.—At Manchester on Tuesday a meeting was held of the Executive committee of the Municipal Corporations in Lancashire and Cheshire opposed to the Lancashire and Cheshire and the South Lancashire and Cheshire Electric Power schemes. Resolutions were adopted that communications should be made with all the municipal corporations in the area of the conference urging them to adopt resolutions for opposing the second reading of the electric power bills.

German Cable to the United States.—A *Daily News* telegram states that a joint stock company has been founded at Cologne with a capital of half a million sterling, to lay a direct cable from Germany to the United States.

Glasgow.—Mr. John Young, general manager of the Tramways, has prepared a draft scheme for the extension of the overhead system to the various routes in the city. The next section recom-

Digitized by Google

mended to be converted is the main east and west route, from Whiteinch to London-road and Dalmarnock, *via* Bridgeton Cross. Mr. Young advises that the work on this route should be begun immediately, and that the others should be taken up in the following order :—Overnewton to Crosshills and Langside, Pollokshaws and Shawlands, and Pollokshields routes from Eglinton Toll outwards. These routes might be joined, for a time at least with the Springburn system, thus avoiding the turning of cars in Mitchell-street. The estimated expenditure providing additional car sheds at Coplawhill, is £25,000, and of equipping the three routes £54,000, in addition to £61,000, the cost of renewing the lines in ordinary course. Mr. Young suggests that the Parkhead and Paisley-road route might then be undertaken, and the Maryhill and Mount Florida, Dennistoun and Kelvinside, Woodlands-road, and Possilpark and Govan lines dealt in the order most practicable. The Tramways Committee have endorsed Mr. Young's recommendation.

Grays (Essex).—The District Council have adopted Mr. A. H. Preece's scheme for the erection of electricity supply works.

Hammersmith (London).—Electric lighting extensions are to be carried out in this district, at an estimated cost of about £13,000. On the recommendation of Mr. G. G. Bell, the electrical engineer, the vestry have decided to engage a staff for the laying of mains.

Increased Discounts.—The St. James' and Pall Mall Electric Lighting Co. announce the allowance of a special discount of 8 per cent. on all accounts under the current scale of charging. The new discount comes into force as from 1st inst.

Inquest.—The adjourned inquest on the engine driver Pugh, who was found dead on his engine on the City and South London Co.'s line on the 10th inst., was resumed on Friday last, when it was announced that a second post-mortem examination of the body had been made in the presence of a number of medical men, including Drs. William Murray-Leslie, Morriss, Henry and Bell. The former medical man, a specialist, stated that the cause of death was syncope from ordinary heart failure. This was confirmed by Dr. Henry and by Dr. Bell. Dr. Morriss, however, adhered to the view that death resulted from electric shock. A fellow driver deposed that he had seen deceased on several occasions go into a dead faint. On that and other evidence the coroner (Mr. Walter Shröder), in summing up, remarked that the jury would have no difficulty in coming to a conclusion that death was not the result of electric shock. The coroner's views, however, had no weight with the jury, who returned a verdict that deceased was killed by an electric shock, but whether the shock was sustained accidentally or otherwise the jury declined to decide.

Lancaster.—A Local Government Board inquiry was held here last week into the application of the Town Council to borrow, amongst other sums, £10,000 for extensions at the electricity supply works. The Town Clerk stated that the demand for electric current rendered the extension of the plant and mains absolutely necessary. There was no opposition.

Light Railways.—The Board of Trade on Wednesday considered the objections of the Worcestershire County Council and the Stourbridge District Council to the confirmation of the order of the Light Railway Commissioners for the construction of an electric railway between Stourbridge and Kinver. Mr. Sydney Morse represented the promoters (the British Electric Traction Co.). After discussion an agreement was arrived at. After hearing an objection by the Kinver Council as to the width of the roadway, Sir Courtenay Boyle intimated that he could not alter the order as drafted by the Commissioners, and he should report to the Board of Trade accordingly.

London County Council.—At Tuesday's meeting it was announced that £11,020 had been loaned to Hammersmith Vestry and £20,000 to Newington (part of £50,000). Islington is to borrow a further £15,000. All these borrowings are for electric lighting extensions.

It was decided to refuse consent to the erection of additions to the works of the Western Electric Co., at North Woolwich, of 250,000 cubic feet extent, and to disapprove of the application of the Blackheath and Greenwich District Electric Light Co. to construct generating works on a site at East Greenwich on the ground that it was undesirable to sanction the construction of a wood and iron temporary enclosure in any part of the building.

Lieut.-Col. Ford has given notice of the following motion :—

"That in face of the application recently made by the Council to Her Majesty's Postmaster-General, with a view to a London municipal telephone service, and in face of the report of the Committee of the House of Commons last session, this Council views with grave concern the aims of the National Telephone Co. as contained in its bills now before Parliament, and accordingly refers it to the Parliamentary Committee to consider, after conference with the Highways Committee, the desirability of petitioning against the said bills, which appear to aim at a grosser and perpetual form of monopoly than that already enjoyed by the company, to the serious injury of the trade and business of the metropolis, which monopoly already deprives the ratepayers of London of a legitimate source of public revenue."

London Telephone Service.—At the conference at the Guildhall of the City of London, on Feb. 1, to consider the question of applying for a licence to establish a telephone service in conjunction with the London County Council and other local authorities within the London telephone area, the following resolutions will be proposed :—"(1) That this conference of delegates, representing the London County Council, the Corporation of London, and the other local authorities within the London telephone area, is of opinion that a joint application should be made for a telephone licence for the London telephone area, in accordance with the resolution passed by the Court of Common Council on Nov. 17, 1898—viz., 'That application be made for a licence to establish a telephone service in conjunction with the London County Council and other local authorities within the London telephone area.' (2) That this conference is of opinion that the London telephone service should be managed by the London County Council and the Corporation of London. (3) That this conference recommends a joint application to the Postmaster-General for the telephone licence, in accordance with the foregoing regulations. (4) That these regulations be submitted to the various authorities represented at this conference for their confirmation."—*Times*.

Manchester.—At a meeting of the Tramways committee, on Tuesday, it was decided to recommend the Corporation to adopt the overhead trolley system throughout the whole of the tramways in the city.

Museum Lighting.—The Trustees of the Natural History Museum, Cromwell-road, London, are making arrangements for introducing the electric light. The work will be executed in sections, and the electric light will be gradually introduced into the various parts of the extensive building—first of all, into the offices and studies of the staff and the workshops in the basement, and then into the various public galleries.

Newcastle-on-Tyne.—After full investigation and mature deliberation the Tramways committee decided, on Wednesday, by 15 votes to 2, to report to the Council in favour of equipping the whole of the old and new tramways of the city on the overhead trolley system. The committee are to consult with the Lighting committee as to the advisability of lighting the streets by means of arc lamps suspended from the trolley posts. A consulting engineer is to be at once appointed to supervise the whole of the work.

Peterborough.—Electric lighting matters seem at last to be making some progress in Peterborough, after the delays occasioned by local opposition. A suitable site has been secured near the river for the Corporation electric lighting station. Dr. J. A. Fleming, F.R.S., consulting engineer to the Corporation, and Mr. J. C. Gill, the borough engineer, are engaged on the plans and specifications. The system to be adopted is the three-wire continuous current, with batteries.

Parliamentary Bills.—The Vestry of St. Margaret and St. John, Westminster (London), invites the co-operation of London local authorities in opposing the bills before Parliament dealing with the construction of underground electric railways. The Vestry suggest that the extension of this class of undertaking should only be permitted when a comprehensive scheme, serving all districts, is presented for parliamentary consideration, such scheme to provide for the convergence of traffic to fixed points, where accommodation would be provided for passengers desiring to travel from one extreme point of London to another.

A petition has been presented to the Vestry of St. James's, Westminster, against the bill of the St. James' and Pall Mall Co. seeking powers to extend their electricity works in Carnaby-street.

The Vestry of Battersea (London) is in communication with other London local authorities as to the advisability of opposing the bill to be introduced by the County of London and Brush Provincial Co. seeking powers to connect up their various areas of supply in London. The Parliamentary committee of the Vestry recommend that the bill should be strongly opposed and seek the assistance of other local authorities in connection with this opposition. The London County Council is to be invited to co-operate.

A Bill has been deposited at the Private Bill office for powers to construct a ferry running on a submerged railway across the river Thames between Greenwich and Milwall. The railway will be worked by electricity, and the ferry will be available for vehicles, foot passengers, animals and general traffic. The gauge of the submerged rails will be 30ft., or such other gauge as the Board of Trade may approve. The capital of the Company will be £250,000, with borrowing powers to the extent of £83,300. The promoters are Mr. H. P. Hussey, Mr. A. F. Hills (Thames Ironworks Co.) and Mr. E. D. Lennox Harvey.

The Lancashire Electric Power Co.'s bill has not passed the examiner of private bills, owing to non-compliance with the Standing Orders. It is stated that the promoters of the two Lancashire electric power schemes intend to ask the assent of the Standing Orders Committee to the suspension of the orders.

Mr. Thoms, one of the examiners of private bills, has held that certain of the allegations of non-compliance with the rules of Par-

Digitized by Google

liament by the promoters of the Leicestershire and Warwickshire Electric Supply Bill have been sustained, and the non-compliance will be referred to the Select Committee on Standing Orders.

Memorials presented against the National Telephone Co.'s Bills through the Standing Orders stage allege that the notices given by the Company of their intended application to Parliament were defective, insufficient, vague, and misleading. It is alleged that the notices were not published in the manner prescribed by the Standing Orders in newspapers circulating in the cities and districts affected by the Bills, whilst the notices that were given in the London, Edinburgh, and Dublin *Gazettes* contained no intimation of some of the principal provisions in the Bills.

St. Giles (London, W.C.).—The Board of Works have finally approved the arrangements made by the Board of Trade in regard to the supply of electrical energy in this district by the Charing Cross and Strand Electricity Supply Corporation under their Holborn and St. Giles Electric Lighting Order, 1895.

Salford.—On Wednesday the Borough Council resumed the discussion on the report of the Electric Lighting committee, recommending the appointment of Messrs. Lacey, Clirehugh and Sillar as consulting engineers. Eventually an amendment that Messrs. Lacey, Clirehugh and Sillar should be appointed consulting engineers, provided that the committee gave the Council an undertaking to set aside the present specifications and start *de novo* was passed.

Scholarship Examinations.—The Board of Control of the Electrical Standardizing, Testing and Training Institution, have made the following awards:—A Maxwell Scholarship of 50 guineas to Mr. Gerald Adamson Hopkins, tenable for two years; an exhibition of 30 guineas to Mr. Thomas Gregory Smith, of Blackheath School, tenable for two years; a prize of 20 guineas to Mr. Leonard Roseveare, of Dunheved College, Launceston.

Southport.—A Local Government Board inquiry was held on Tuesday into the appplication of the Town Council to borrow £3,500 for electric lighting purposes.

Telephone Span Wires.—The National Telephone Co., in its application to the Islington (London) Vestry for permission to work certain overhead wires in spans exceeding the distance allowed by the London Overhead Wires Act, points out that every effort is being made to reduce the length of spans where such have exceeded the limits allowed by the act. It is intimated, however, that it is impossible to undertake to shorten these spans unless the company is granted compulsory powers. If the company cannot obtain from the Vestry an extension of the six months allowed some time back for altering the spans, it is intimated that these lines will have to be taken down and the subscribers disconnected.

Windsor Castle.—Electric current is to be taken from the mains of the Windsor Electric Installation Co. for the lighting of Windsor Castle. Hitherto current has been generated at an independent station under the north terrace opposite the royal library. The work is to be completed before Her Majesty's return from Osborne.

Workhouse Lighting.—The Ecclesall (Sheffield) Board of Guardians are ascertaining the cost of lighting the new hospital and administrative block electrically.

Electro-Harmonic Society.—A smoking concert will be given at the St. James's Hall Restaurant, Regent-street, W., this (Friday) evening at eight o'clock.

Staff Dinner.—On Saturday last the staffs of the London and Belvedere offices of Callender's Cable and Construction Co. (Limited) held their first annual dinner at the Bridge House Hotel, London Bridge, Mr. Manning (secretary) occupying the chair and Mr. Johnston (manager at Belvedere) the vice chair. A large company enjoyed a pleasant evening.

COMPANIES' MEETINGS AND REPORTS.

Eastern Telegraph Co. (Limited).

The fifty-third half-yearly ordinary general meeting of this Company was held on Thursday, January 19, 1899, at Winchester House, Old Broad-street, London, under the presidency of the Marquess of TWEEDDALE, K.T., "to receive the Directors' report and accounts, elect Directors and auditors, and transact the ordinary business of the Company."

The SECRETARY (Mr. George Draper) having read the notice convening the meeting and the minutes of the fifty-second half-yearly and of the extraordinary general meetings held on July 21, 1898,

The CHAIRMAN (having signed the minutes) continued: Gentlemen, I have now to ask your approval of the report and accounts for the first half of our financial year, and in doing so I shall, as usual, draw your attention to the more important features of the business of the last half-year. The gross revenue for the half-year under review amounted to £444,011, or an increase of £284 as compared with that for the corresponding period of 1897.

With regard to this increase, I may mention that during the September half of 1897 we derived extra traffic from Crete, owing to the disturbed condition of that island, but the traffic has resumed its normal state in the half-year under review. There are other fluctuations in various classes of our traffic, but in no case are they important enough to demand any special attention.

The total ordinary expenses for the half-year ended September 30, 1898 amounted to £121,376, or an increase of £12,133. This increase comprises in the present half-year's figures several items of an exceptional character which did not appear in the corresponding period. For instance, duty on new capital, which was issued with your sanction, cost £2,000; then the expenses in connection with the conversion of shares and the issue of new stock amounted to £662; there is also the item under the heading of "Negotiations with foreign Governments, &c.," £3,942. This latter item relates to expenses which have been incurred in connection with different businesses which we are considering, the nature of which will be intimated to you when they come to a conclusion. There is also a subscription which we made to the West Indies Relief Fund of £26. Those items make a total of £6,630, for what may be described as extraordinary expenses. The increase, therefore, in the ordinary expenses may be put at £5,503.

The nature of this increase was fully explained at the last meeting, when it was attributed to the introduction of the automatic system of signalling necessitating additions to our staff, and also to the cost of improved electrical apparatus, together with the various expenses incidental to the necessary increased number of our employés.

If we compare the present half-year's figures with those submitted at the last general meeting, after deducting in each case the items of an exceptional character, you will find that the increase is comparatively very little. I may remark, however, that our expenses have a tendency to grow in a greater ratio than the revenue. I have dealt with this subject on former occasions, but as it is a very important one in connection with the affairs of the Company, I need not apologise for again referring to it.

We have always, as you are aware, kept in mind that a company like ours exists for the benefit of the public as well as for that of its shareholders, and we have, therefore, spent, and shall continue to spend, large sums in improving the efficiency of our service by increasing the number of our cables, by the introduction of the most modern plant and electrical appliances, and by dealing liberally with our staff.

Again, we have from time to time made extensive, and may make still further, reductions in our rates. All this entails considerable increase in our working expenses, while the lowering of our rates, although generally followed by a greater volume of traffic, does not always ensure an increase in our revenue. In fact, not infrequently the contrary is the case. It is only, therefore, by the exercise of strict and judicious economy—consistent with efficiency—that the working expenses can be kept within proper limits. This duty, I can assure you, is never lost sight of, and you may rely upon it that when any increase of expenditure takes place it will be shown to be fully justified.

For the reasons given at the last general meeting—which were that we had re-arranged our headings with the view of our making more careful comparisons in future—it will not be possible to compare the several items in abstracts "A" and "B" with those of the corresponding period of 1897. As compared with last half-year, however, you will find that the general expenses in London amounted to £12,875, showing a decrease of £49. Working expenses at stations were £93,589, showing an increase of £2,328 as compared with those of last half-year. This increase is mainly due to annual promotions and the increase in number of the staff at the stations. There is also an increase under the heading of electrical instruments, stationery and printing, but a decrease under several of the other headings—such as furniture, land lines, &c.—all of which are more or less subject to fluctuation.

Expenses attending repairs and renewals of cables amounted to £41,716, or an increase of £10,079. In comparing the actual ships' expenses we find a decrease of £2,571. The increase in the total is due to the large amount of cable used on repairs, the Malta-Alexandria No. 2 cable (a very old one—about 28 years old) alone requiring no less than 222 knots. The amount received from Governments and other companies for repairs to their cables during the half-year was £7,172 less than in the corresponding period of last year.

The charge against revenue for interest on Preference shares and Three and a-Half Preference stock is £4,399 more than in the corresponding period of 1897. The dividend for the quarter ended June 30 on the old Preference shares was the same as in the previous year, but the dividend on the Preference stock for the September quarter was £4,399 more than the dividend on the Preference shares during the same quarter in 1897. This is made up partly of the increase that was given to the Preference shareholders when the conversion took place, and it also includes the dividend on that portion of the additional issue of £500,000 stock which was paid up in July last, and was, therefore, entitled to dividend for the September quarter.

The net result of the working during the half-year may be briefly summed up as follows:—The gross revenue amounted, as I have already said, to practically the same figure as last year, but the working expenses, the expenses in connection with repairs to cables, and the charges against revenue in respect of dividend on the additional amount of Preference stock were all heavier, so that we carry £5,000 less to the general reserve fund, £15,000 less to the minor reserves, and £6,457 less balance forward to next half-year. Notwithstanding these reductions, gentlemen, I think, after the explanations which I have given you, you will consider the result of the half-year's working highly satisfactory. I am glad to be able to add that the receipts so far as we have gone in the current half-year have been fully maintained.

I mentioned at the last meeting that the conversion of the Six per Cent. Preference shares into Three and a-Half per Cent. Preference stock had been successfully effected. You will see by paragraph 6 of the report that the Ordinary shares have also been converted into stock, and that the Stock Exchange has granted official quotations for both classes of stock. The work in connection with these operations has necessarily been very heavy, but it has been expeditiously carried through, with the least possible inconvenience to our shareholders and others concerned. The Preference stock certificates have practically been all issued, and the greater portion (about 8,000) of the Ordinary certificates have been issued, but there are still about 800 shareholders who have not sent in their old Ordinary share certificates to be exchanged for Ordinary stock certificates. If there should be anyone here who has not done so, we shall feel obliged by his giving the matter attention without delay.

With reference to the additional cables between Porthcurnow and Gibraltar, and Malta and Alexandria, you will see from the report that the first section has been laid. Since the report was issued the remaining sections between Gibraltar and Malta and Malta and Alexandria have also been successfully completed, and will shortly be opened for traffic. When this is done, the telegraphic service between Great Britain, Egypt, and the Far East will be greatly improved. The cost of these cables will be taken partly from the general reserve fund.

Digitized by Google

We have under consideration tenders for a new cable repairing steamer to replace the "John Pender," which has been sold. We did not part with the old ship without some feelings of regret, although she was somewhat antiquated as regards her hull and propelling power. During her service as a repairing steamer she did a great deal of good and useful work, but the axiom, "Time is money," is peculiarly applicable to the repair of cables, and we considered it was very desirable, therefore, to replace her by a larger and faster vessel, and one capable of carrying a larger quantity of cable. The amount received for the old ship will be credited to the maintenance ships' fund, and the cost of the new vessel will be taken out of that fund.

I think that I have now touched on all the important matters connected with our business during the half year under review, and I will, therefore, conclude by moving—

"*That the report and accounts of the Directors to September 30, 1898, submitted to this meeting, be and the same are hereby received and adopted.*"

The VICE-CHAIRMAN and MANAGING DIRECTOR (Mr. J. Denison-Pender): I have pleasure in seconding that resolution.

The CHAIRMAN: You have heard the resolution moved by myself and seconded by Mr. John Denison-Pender; and those who are in favour of it will please signify the same in the usual manner. Those of a contrary opinion. Carried unanimously. Then, gentlemen, although this is the first half of the year, yet, under our Articles, Directors are re-elected, and therefore, I am going now to move—

"*That Clement Sneyd Colvin, Esq., C.S.I., who now retires, be and he is hereby re-elected a Director of the Company.*"

The VICE-CHAIRMAN and MANAGING DIRECTOR: I have also the pleasure of seconding that motion.

The CHAIRMAN put the motion in the usual way, and having declared it carried unanimously, said: I now propose—

"*That Sir Henry Charles Fischer, C.M.G., who now retires, be and he is hereby re-elected a Director of the Company.*"

Sir ALBERT J. LEPPOC CAPPEL: I have much pleasure in seconding that.

The CHAIRMAN put the motion and declared it carried unanimously. Continuing, he said: The next resolution relates to the appointment of auditors, and that will be moved in the body of the hall.

Mr. MUIR (a shareholder): I beg to propose the following resolution—

"*That the firms of Messrs. Deloitte, Dever, Griffiths and Co. and Messrs. Welton, Jones and Co. be and they are hereby elected auditors to the Company for the ensuing year, at a remuneration of £100 to each firm.*"

Mr. ANSELL (a shareholder): I beg to second that.

The CHAIRMAN: The resolution which you have just heard read has been proposed by Mr. Muir and seconded by Mr. Ansell. Those who approve it will please to signify the same in the usual way. On the contrary. Carried unanimously. Gentlemen, that constitutes the business of the ordinary meeting; but there is an extraordinary meeting, of which you have had notice, and I will ask the Secretary to read the notice.

The SECRETARY accordingly read the advertisement convening the Extraordinary General Meeting, which was for the purpose of considering and, if thought fit, passing the following resolutions:—

"*1. That Article 29 of the Company's Articles of Association be altered by striking out the amount £10, and inserting in lieu thereof £1.*"

"*2. That the Directors of the Company be and they are hereby authorised (in accordance with Section 6 of the Eastern Telegraph Company's Act, 1898) from time to time to create and issue Debentures or Debenture stock charged on the revenue and undertaking of the Company, so, however, that the total amount of Debentures or Debenture stock for the time being created and issued shall not exceed one-third of the total amount of the capital in Ordinary and Preference stock and shares for the time being created and issued and paid up, and so that all Debentures or Debenture stock created and issued by virtue of this section shall rank* pari passu *with the existing 4 per centum Debenture stock of the Company.*"

The CHAIRMAN: Gentlemen, before asking the meeting to pass the resolutions which have just been read, I will explain the necessity for altering the Articles of Association in the first instance, and the advisability of granting powers to the Directors to issue from time to time the balance of the mortgage debenture stock in the second place. With regard to the first resolution, I will read the Article as it at present stands:—

"When any ordinary shares shall have been converted into stock, the several holders of such stock may thenceforth transfer their respective interest therein, or any part of such interest, not less than £10 in nominal amount, and not comprising any fractional part of a £, in the same manner, and subject to the same regulations, as and subject to which any shares in the capital of the Company may be transferred, or as near thereto as circumstances admit."

You will see that the Article limits the dealings in the ordinary stock to a minimum of £10, but as the preference stock can be dealt with in multiples of £1, it is considered that the holders of ordinary stock should have at least the same facilities in dealing as the holders of preference stock, and, unless we alter the Article, it may cause considerable inconvenience to the holders of ordinary stock. For instance, supposing a holder of £100 stock wished to transfer £95, he could do so according to the present conditions, but as there would be £5 remaining in his account, he could not transfer it, because it would be under the minimum of £10 limited by the Article. So much with reference to the first resolution.

With regard to the second resolution, according to the terms of the special resolution annexed to the original prospectus, the Board of Directors were authorised from time to time to create and issue mortgage debenture stock of the Company to an amount not exceeding one-third of the share capital of the Company for the time being paid up. But when the conditions under which this stock could be issued were embodied in the Eastern Telegraph Co.'s Act of 1898, powers to create additional debenture capital were granted, subject to the sanction of the members in general meeting.

It may frequently happen that it is advisable to issue small portions of this stock in order to acquire shares in other telegraph companies, or for other capital purposes; and also to exchange this stock on certain terms for the Five per Cent. Debentures repayable in 1899, and it would be inconvenient to call a special general meeting of shareholders every time it was found expedient to issue a small portion of the stock. We are therefore asking you to renew the powers which you granted to us when this stock was originally created. I may mention that so far as we know at present there is no necessity to issue any portion of the Four per Cent. Mortgage Debenture stock. Gentlemen, with these explanations, which I hope have been sufficient—and, if not, I shall be glad to answer any questions, or to ask the solicitor to do so—I will move these resolutions.

The SOLICITOR (Mr. Dawes): Do not read them again, my lord; let them be taken as read.

The CHAIRMAN: I beg to move the first resolution, which the Secretary read to you, and which you have at the back of the report, as to the alteration in Article 29.

Mr. GOODSALL: With respect to the issue of debentures, will you give the shareholders the first chance of taking them; and will the stock be issued at par, and not at a premium?

The CHAIRMAN: We are always disposed, as far as we can, to favour our shareholders. I think the shareholders present will admit that; but I should be indisposed to bind the Board to any promise. We have always shown, on every occasion, our disposition, as I say, to do all we can to meet the wishes of the shareholders, and, therefore, I think that you had better leave this matter in our hands with the assurance I have given. I now beg to move that resolution.

The VICE-CHAIRMAN: I beg to second it.

The CHAIRMAN put the motion in the usual way, and having declared it carried unanimously, said: I now move the other resolution, which is seconded by Mr. Denison-Pender in the same way. Having put the motion to the meeting and declared it carried unanimously, he said: That constitutes the business of our meeting.

Mr. PARITT: One word, gentlemen, before we part. There is always a pleasant duty which devolves on us at these meetings—to pass a vote of thanks to our noble Chairman and the gentlemen who sit with him for their services to us in the past six months, and for the very able report which they have been able to present to us again, I am sure we shall also wish to thank them. We must congratulate ourselves, I think, when we find that we are going along so prosperously. Therefore, it is my very great pleasure to propose a vote of thanks to the Chairman and the gentlemen who sit with him at the Board; nor must we forget our worthy Secretary, and the other members of the staff generally. In doing so, I must at the same time congratulate his lordship on the honour which Her Majesty has conferred on him in the distinction of Knight of the Thistle (cheers). It is out of our power to give him any decoration except to make him our Chairman, which is the highest decoration we can confer on him. The honour which has been bestowed on him has been without a doubt well deserved. I beg now, gentlemen, to propose a vote of thanks to our Chairman and all who have worked with him, and made the Eastern Telegraph Co. the valuable institution that it now is.

Mr. G. B. SYMES: I will second it.

The SOLICITOR put the resolution to the meeting in the usual way, and it was carried unanimously.

The CHAIRMAN: I beg to thank you for this vote on the part of my co-Directors and the staff, who, I understood, were embraced—and very properly embraced—in the vote of thanks. I have also to return my acknowledgments for the kind way in which the honour which has been conferred upon me has been alluded to. Let me assure you that I appreciate your goodwill quite as much as any other honour. I am very grateful for the cordial reception you have given to this motion, and I hope that when we next meet we shall be able to give you a dividend which will make you equally satisfied as you are on the present occasion (hear, hear).

The proceedings then terminated.

Yorkshire House-to-House Electricity Co. (Limited).

A general meeting of this Company (whose undertaking has now been purchased by the Leeds Corporation) was held on Wednesday, Mr. GROSVENOR TALBOT presiding.

The CHAIRMAN, in moving the adoption of the report and accounts, said that presumably this was the last annual meeting of the shareholders of the Company that would be held. The Company had been successful from its initiation, and he was confident it would have continued as successfully as in the past. It was a great satisfaction to him personally that round that table were assembled the Directors and solicitor with which the Company was initiated. They had paid during the past year an interim dividend at the rate of 5 per cent. per annum for the half year to June 30, and had now to dispose of £7,068. 19s. 5d. That amount they proposed to pay wholly in dividend. The amount available, with the interim dividend, would equal 6¾ per cent. for the year to Dec. 31, 1898, and a small balance of £87. 9s. 9d. was carried forward. That dividend showed that they were handing over to the Corporation a flourishing concern. The number of lamps the Company had installed in December, 1897, was 49,150; and at the end of September, 1898, 65,328, an increase of 16,178 lamps in the nine months. If they could have carried out installations at the same rate for the whole year, it would have shown an increase at the rate of over 40 per cent. for the year. They were told by some people in the town that they had increased their capital unduly, merely for the sake of inflating the profits of the Company. He thought he had shown that that was absolutely absurd, because they did not increase the capital at any greater rate than they increased the number of lamps installed; and, as a further proof, the Corporation saw the necessity of continuing their policy, and the newspapers told them that they had gone into an additional expenditure of

Digitized by Google

£45,000. They had now in hand £217,420 of Corporation Five per Cent. Irredeemable stock, which would have to be dealt with in the future by the liquidator of the Company. That was very valuable stock, and it would be handed over to the shareholders in their due proportion. He felt he must at this meeting express his thanks, and the thanks of his colleagues, to those gentlemen who had worked with them so heartily from the commencement of their undertaking:—Mr. Hammond, the consulting engineer; Mr. Barr, the solicitor; Mr. France, the architect; Mr. Green, the secretary; Mr. Dickinson, the electrical engineer, and others.

The resolution was adopted.

The Chairman and Mr. R. W. Eddison were re-elected Directors.

The CHAIRMAN proposed that they should grant a honorarium to Mr. Dickinson and Mr. Green, of 100 guineas each. He thought that was the least they could do to show their indebtedness to these two men, who had given such untiring devotion to their work during the last six years.

This resolution was adopted unanimously, and, after a formal resolution to wind the Company up voluntarily, and a vote of thanks to the Chairman and Directors had been passed, the proceedings terminated.

City and South London Railway Co.

The following report of the Directors of this company for the half-year to Dec. 31 last will be presented to the half-yearly meeting of shareholders, on Tuesday, 31st inst.:—The receipts from all sources have amounted to £27,588. 9s. 4d., and the cost of working has been £15,498. 5s. 7d., leaving a profit of £12,090. 3s. 9d. Inclusive of balance brought forward, the net revenue account shows a total of £13,171. 0s. 8d. After making provision for Debenture stock interest, a balance is available for dividend of £10,190. 12s. 9d., and the Directors recommend that the full dividend be paid on the Five per Cent. Preference shares, and a dividend at the rate of 2 per cent. per annum on the Consolidated Ordinary stock, leaving £1,419. 12s. 6d. to be carried forward.

The number of passengers (exclusive of season ticket holders) carried during the half-year shows a considerable increase over the corresponding half-year of 1897.

The progress of the Moorgate-street extension has been uninterrupted; both tunnels are completed from the junction with the present line at the Borough to Moorgate-street station, and the three underground stations are almost finished. The shafts are ready for the lifts, the erection of which has already been commenced. The laying of the permanent way is also well advanced, and the subway communication between the Lombard-street station of this company and the Bank station of the Central London has been constructed. The station buildings on the surface at Moorgate-street, Lombard-street and London Bridge will be commenced forthwith. The works of the extension from Stockwell to Clapham Common are progressing very satisfactorily, and it is anticipated that the line will be completed ready for traffic early in the autumn of this year. The erection of the new boiler and engine house at the depôt at Stockwell is proceeding rapidly, and will be ready for the erection of the engines in March. The three locomotives referred to in the last report have been delivered, and, as their working has given satisfaction, tenders for the full number required are now being invited. The thirty additional coaches required are now in course of delivery.

The works of the extension through the heart of the City having now been completed, it is necessary, in order to utilise fully this valuable portion of the line, that the remainder of the authorised undertaking, carrying the line to the Angel at Islington, and thus bringing in the traffic from the north as well as from the south, should at once be proceeded with, and steps have already been taken to secure the site of one of the three stations along the route. It is proposed to let the contract for the works as soon as favourable arrangements can be made. It is anticipated that this portion of the railway will be constructed at a very moderate cost, and can be worked economically, with power supplied from the generating station at Stockwell.

Negotiations are in progress with the London, Brighton, and South Coast Railway Co., for the construction of the subway authorised by the Act of 1893, connecting this company's new station at Denman-street with the London Bridge station of the Brighton company.

In order to further facilitate and economise the working of the City and Brixton Railway, which, when completed, is to be leased to this company, it has been arranged that, in lieu of providing a separate depôt for the Brixton Company, a short tunnel should be made connecting that company's line with this company's depôt at Stockwell. A bill has been introduced into Parliament with this object.

Direct United States Cable Co. (Limited).

The report of the Directors of this company for the six months to Dec. 31 last states that the half-year's revenue, after deducting out-payments, amounted to £54,366. 4s. 10d. compared with £50,098. 2s. 8d. for the corresponding period of 1897, an increase of £4,268. 2s. 2d. The working and other expenses for the same period, including income tax, amounted to £21,620. 19s. 11d., leaving £32,745. 4s. 11d. as net profit, making, with £3,388. 11s. 9d. brought forward, £36,133. 16s. 8d. Interim dividends of 3s. per share for the quarter ended Sept. 30 and of 3s. per share for the quarter ended Dec. 31 (taking £18,213) have been declared, and after setting aside £12,000 to reserve, the balance of £5,920. 16s. 8d. has been carried forward.

No repairs of the cables have been necessary during the half-year. Reserve has been debited with £1,548. 0s. 2d., the balance of the Ballinskelligs buildings and Rye Beach land accounts now written off, and after being credited with interest, realised profit and sum transferred from revenue the balance of the reserve fund, taking the investments at cost price is now £368,534. 1s. 7d.

NEW COMPANIES, STATUTORY RETURNS, &c.

GIFFRE ELECTRO-CHEMICAL AND POWER CO. (LIMITED).—This company was registered on Jan. 18, with a capital of £140,000 in £1 shares, to acquire all or any of the capital, stock, debentures, obligations or securities of the Societe Electro-Chimique du Giffre, to work, develop, and manufacture any articles in accordance with any chemical, electro-chemical, or electrical process, to manufacture, sell and deal in carbide of calcium, and to carry on the business of chemists, &c. The first Directors are:—W. H. Grenfell, John Paddon and Ernest E. Sawyer.

RECORDING TELEGRAPHS (LIMITED).—This company was registered on Jan. 17, with a capital of £7,500 in £50 shares, to subscribe for, underwrite, issue, deal in and convert stocks, shares and securities, and to acquire, develop and deal with any letters patent, brevets d'invention, or rights. The first subscribers are: Capt. R. L. Cowper-Coles, Walter T. Goolden, civil engineer, E. J. Wood, electrical engineer, J. A. Currie, E. P. Reynolds, C. E. Spagnoletti, electrical engineer, and E. E. Cobb.

MATHER AND PLATT (LIMITED).—This company was registered on Jan. 21, with a capital of £775,000, in £10 shares (of which 37,500 are £5 per Cent. Cumulative Preference), to acquire and take over as going concerns the businesses of Mather and Platt, Limited (incorporated in 1892), and of Dowson, Taylor and Co. (Limited), and to carry on the business of mechanical, electrical and hydraulic engineers, machinists, tool makers, boiler makers, founders, metal workers, electricians, &c. The first Directors are: William Mather (chairman), John Platt, Edward Hopkinson, John Taylor, Colin Mather, John Milligan, Hardman A. Earle, John Wormald, J. J. Holden, W. Ernest Mather and Alfred Willett.

AUTOMATIC TELEPHONE CO. (LIMITED).—The annual return, to Jan. 6, has been filed. The capital is £100,000, in 5s. shares, and 314,326 of these have been taken up. 270,296 have been issued as fully paid, and 4s. per share has been called on 17,620, and 1s. per share on the remaining 25,410 shares.

HAMPSTEAD ELECTRIC SUPPLY CO. (LIMITED).—This company's statutory return, to Dec. 4, was filed on Jan. 13. The capital is £200,000, divided into 20,000 Preference and 20,000 Ordinary shares of £5 each. 6,589 of the former and 6,000 of the latter have been taken up, and the full amount has been called, resulting in the receipt of 58,647. 12s. 4d., and leaving £4,297. 7s. 8d. in arrears.

SMITHFIELD MARKETS ELECTRIC SUPPLY CO. (LIMITED).—The annual return, to Jan. 6, has been filed. The capital is £100,000, in £5 shares. 12,000 of these have been taken up and the full amount has been called.

CITY NOTES.

MEMORANDA.—Bank rate 4 per cent. (since Jan. 19, 1899). Price of silver 27⅜d. per oz. (Jan. 26). Consols (2¾ per cent.) 111—111⅛ for money, 111 1/16—111 3/16 for account; 2½ per cent. 103½—104½ (Jan. 26). Stock Exchange Settling Days: Consols, Feb. 1; Stocks and Shares Continuation Days, Feb. 8 and 22; Ticket Days, Feb. 9 and 23; Pay Days, Jan. 27 and Feb. 10; Mining Share Carry over Days, Feb. 7 and 21.

AMERICAN LIGHTING TRUST.—An effort is being made to form a combination, with a capital of $60,000,000, for the purpose of controlling the electric lighting and gas undertakings of Southern Indiana and Ohio.

ANGLO-AMERICAN TELEGRAPH CO. (LIMITED).—After placing £12,000 to renewal fund for the half year the directors recommend the declaration of the following dividends:—Balance dividend of £1. 4s. per cent. on the Ordinary Consolidated stock, balance dividend of £1. 10s. per cent. on the Preferred stock, and a first and final dividend of 18s. per cent. upon the Deferred stock for the year to Dec. 31 last, payable on Feb. 4, less tax. The balance is about £580. These dividends, together with those already paid, amount to £3. 9s. per cent. on the Ordinary Consolidated stock, £6. per cent. on the Preferred stock, and 18s. per cent. on the Deferred stock for the year 1898.

BARCELONA TRAMWAYS CO. (LIMITED).—The secretary of this company notifies that negotiations have been entered into for the sale of the company's undertaking at Barcelona, and the Board believe that the arrangements will be brought to a satisfactory conclusion at an early date. The lines will then be equipped electrically.

BLACKPOOL AND FLEETWOOD TRAMROAD CO.—The general meeting will take place at Manchester on Feb. 10.

CHAMBERLAIN AND HOOKHAM (LIMITED).—Subscriptions have this week been invited for 4,000 Cumulative Preference shares of £5 each at par in this company, which was registered in 1883, and has now been reconstructed in order to bring in more capital, enlarge the business and put the preference shares on the market. The new company takes over the assets of the old as from Jan. 1, 1898. The working of the old company for 1898 (the prospectus states) showed, after paying a dividend of 7½ per cent. on the paid-up Preference capital and of 5 per cent. on the Ordinary shares, a balance of undivided profit of over £25,000 to be carried forward. The list closes on or before 31st inst.

CHARING CROSS AND STRAND ELECTRICITY SUPPLY CORPORATION (LIMITED).—The Directors of this corporation, after providing £7,000 for depreciation, carrying forward £3,500, have decided, subject to audit, to recommend a dividend for the half-year ended Dec. 31 at the rate of 10 per cent. per annum, making (with the interim dividend at the rate of 6 per cent. per annum for the June half year) 8 per cent. for the year on the ordinary share capital.

ELECTRICAL JOINT STOCK ENTERPRISE.—The *Investors' Guardian*, in a review of joint stock enterprise of 1898, gives the following figures

Digitized by Google

regarding electrical companies for 1896-7-8. The total capital of English electrical companies for 1896 was £9,768,705, 1897 £5,059,800, 1898 £3,452,364; Scottish companies: 1898 £211,600; Irish companies: 1898 *n l*. For telephone ventures the English figures are for 1896 £264,000, 1897 £54,000, 1898 £854,000; Scottish companies *nil*; Irish companies *nil*.

GIFFRE ELECTRO-CHEMICAL AND POWER CO. (LIMITED).—Subscriptions have been invited this week by the General Water Power (Limited), for 130,000 shares of £1 each in the above company, which has been formed to acquire the shares of a French company, carrying on business in Haute Savoie, France. The assets of the French company include leases of certain lands, lime kilns, electric furnaces, and a factory containing from 1,000 H.P. dynamos, offices and works, &c., &c. It is stated that the requisite turbines and dynamos for an output of 4,200 E.H.P. are now in working order, and that an additional installation of equal power is to be completed by June 1 next. It is claimed that carbide of calcium can be economically manufactured at Giffre of exceptionally high quality. We are told that the capital required has already been subscribed.

HAMPSTEAD ELECTRIC SUPPLY CO. (LIMITED).—A firm of outside brokers has been issuing broadcast a circular inviting purchase of shares in the above-named company at £4. 19s. for the £5 share. The concern was introduced at the end of July last. It has *no* parliamentary powers, and operates by means of overhead wires—an antiquated method altogether—for the wayleaves for which it has to rely upon the good graces of every owner of property over which its wires pass. Its business could at any time be dislocated by the transfer of property. And what the maintenance of wayleaves means has been indicated by the experience of the old Brighton company, which had overhead wires and no statutory powers, and worked in opposition to the Corporation, who had underground mains and a provisional order. In the end the company went to the wall, and the Corporation got the business for £5,000. In Hampstead the Vestry have a provisional order under the Electric Lighting Acts, and give a splendid supply at a fairly cheap rate. The company is an opposition concern with overhead wires, and in time it must go. The prospect for shareholders is poor indeed, because the Vestry will never buy; they have no need to do so. The circular above mentioned sets out a number of electric-lighting shares, with their prices and dividends, but they are all of companies established under statutory powers, and the comparison of Hampstead with them is ludicrous.—*The Statist*.

LIVERPOOL OVERHEAD RAILWAY CO.—The accounts of this company for the past half-year show an available balance of £16,586, and the Directors have resolved to recommend payment of a dividend at the rate of 5 per cent. per annum on the Preference shares and 4 per cent. per annum on the Ordinary shares, against 3½ per cent. per annum on the Ordinary shares for the corresponding period last year. The balance carried forward is £4,586, against £2,878 last year.

METROPOLITAN RAILWAY CO.—In their half-yearly report, the Directors state that the arrangements for the experimental electrical working of the line between Earl's Court and High-street, Kensington, are well advanced, and that the work will be completed in about nine months' time.

NATIONAL TELEPHONE CO. (LIMITED).—Subject to final audit, the following dividends are recommended for the half-year to Dec. 31 last:—At the rate of 6 per cent. per annum, less tax, on the First and Second Preference shares; at the rate of 5 per cent. per annum, less tax, on the Third Preference shares; at the rate of 6 per cent. per annum, free of tax, on the Ordinary shares; carrying £50,000 to reserve and about £8,000 forward. The transfer books will be closed from 4th to 17th Feb.

ST. JAMES' AND PALL MALL ELECTRIC LIGHT CO. (LIMITED)—The Directors of this company recommend a dividend for the half-year ended Dec. 31 of 7s. 6d., together with a bonus of 2s. per share on the Ordinary shares, making, with the interim, a dividend of 12½ per cent., and a bonus of 2 per cent. for the year 1898.

WATERLOO AND CITY RAILWAY CO.—The Directors recommend a dividend on the Ordinary stock at the rate of 3 per cent. per annum for the half-year ended Dec. 31.

WESTERN AND BRAZILIAN TELEGRAPH CO. (LIMITED).—The numbers are published of the 190 Six per Cent. debentures (series "A" and "B") of this company, which have been drawn for payment at par on Feb. 2.

NOTES.

MR. PREECE'S next birthday, falling about ten days from now, is giving rise to a multitude of Press rumours, more or less in the nature of guesses, but most of them substantially true, though mistaken in detail. It is not the fact that the Engineer-in-Chief and Electrician of the Post Office will be asked to remain in his present post; and it is well known that he does not wish to remain there. All the same his services will not be lost to the Post Office, for the very sufficient reason that they cannot be dispensed with at this juncture. Mr. PREECE is bound to quit his post, the Treasury having "no funds"—so the fiction runs—to pay the holder of any office after he has reached his sixty-fifth birthday; but, by a still more pleasing fiction, a retiring officer may be employed (and handsomely paid) under a different title, though his appointment has been vacated. It requires no gift of prophecy, therefore, to predict with tolerable confidence that the course contemplated in Mr. PREECE's case will be to retain him in some such capacity as advising electrical engineer to the POSTMASTER-GENERAL, but to allow him that freedom of action which a man of his eminence in the profession outside the Department may justly claim as an alternative to the complete severance of all official ties. Mr. PREECE's position in that case will remain virtually what it has been hitherto, but it will be, as the phrase goes, "a position of greater freedom." We hope to congratulate him on the arrangement, whatever it may be, and wish him many happy returns of the day.

AN important principle is involved in the decision of the Court of Appeal to reverse Sir FRANCIS JEUNE's decision of last April to the effect that the County of London and Brush Provincial Electric Lighting Co. would have to remove the mains laid by them without the sanction of the Vestry of St. Mary, Battersea. It was stated in the Court of first instance that the Company had laid about 77ft. of mains, at a depth of 2ft., within the parish of Battersea, the whole of the work being carried out on a Sunday. All previous attempts to negotiate with the Vestry having failed, the Company had adopted this course as a last resource; but Sir FRANCIS JEUNE decided that the act was illegal, and that the Company would have to remove the mains and pipes thus laid. The decision of the MASTER OF THE ROLLS and Lord Justices RIGBY and VAUGHAN WILLIAMS on Monday, however, was to the effect that by thus clandestinely laying pipes and mains the Company had in no way interfered with the statutory rights of the Vestry. One of their Lordships characterised the action of the Company as "high-handed," and regretted that he could not deprive them of any advantage they had gained by their "lawless conduct." At the same time, their Lordships concurred in the opinion that, as the Vestry existed only for the public good, by its refusal to grant permission to the Company to lay its mains, when it might have granted such permission without any injury to the public, it had placed itself in the wrong.

THE sagacity and mere worldly wisdom of local authorities is not brilliantly displayed in the conduct of the Battersea Vestry. In the first instance it refused a lump sum from the Company for granting the latter the way-leaves necessary for the proper conduct of its business; then it haggled over an annual payment, demanding the ridiculously large sum of £50 a year for the way-leave for less than 100ft. of main; finally, it has been told by the Court of Appeal that the Vestry's statutory rights have not been violated, and it will have to allow the mains to stay without being entitled to any payment whatever. *Verbum sap.*

OUR correspondent in Japan sends us a number of interesting notes on the progress of electrical industry in the land of the chrysanthemum. These, together with a map of the electric supply stations in Japan, will be found on a later page in our issue this week. Few of our readers will regard this map without feelings of surprise, for it reveals the astonishing fact that there are no less than 44 public undertakings for the supply of electric light and power. Eleven of these are driven by water-power, of which there is abundance in many parts

Digitized by Google

of the Japanese islands; the remainder being driven by steam. In addition to these public concerns, there is a very large unconsidered residue of private installations.

In another column we publish the complete text of Major Cardew's report on the Southampton accident. The facts of the case were clear and uncontested: In a street box were a number of temporary joints in high and low-pressure cables, jumbled together in some confusion. The insulation of one of these joints was found to be defective, and a man was sent down to re-tape it. Everyone connected with the affair seems to have known that there were "live" high-pressure joints in the box, but it was thought that the defective joint was a low-pressure one. This was erroneous, and in consequence the unfortunate workman received a shock which killed him.

Although the deaths from electric shock in this country have not been very numerous, the majority of them would have been avoided if reasonable precautions had not been neglected. In some cases negligence on the part of the victims themselves has been the prime cause, while in others their superiors have not been entirely free, at any rate from moral blame. In commenting on the occurrence at the time of the inquest, we pointed out that there was no apparent reason why the high-pressure mains should not have been switched off, and we see that Major Cardew is of the same opinion. Even if the cables had not been seen to be tangled or crossed, and if the joint to be re-taped had actually been a low-pressure one, it was running needless risk to work in the street-box while other temporary joints there were charged at high pressure. We feel bound to express the opinion that another has been added to the list of accidents which might easily have been avoided.

Major Cardew, in his report, calls attention to the danger of high-pressure mains being mistaken for low-pressure ones, and suggests that the attention of manufacturers should be directed to this point. It would be interesting to hear some cable-manufacturers' views on the matter. There would appear to be no difficulty in passing lead-covered cables through a thick red paint before sending them out, or in giving the compound, in which taped or braided cables are impregnated the colour of a danger-signal. Such a step would, however, be worse than useless if the colour were liable to wear off or to don the "customary suits of solemn black," and perhaps a better plan would be to give *low*-pressure cables a distinctive colour, say a bright green, wherever they were brought into proximity with high-pressure ones. The cost of this pigment would be small, and would hardly increase the price of the cable, but even were this not the case, money spent on ensuring the safety of *employés* is never money badly spent.

Cable Interruption.—

	Date of Interruption.
Para—Maranham	Nov. 15. 1898

Conduit Explosions.—Explosions have been occurring in the electric lighting conduits at Persignan (France), and the Mayor has decreed that the conduits are to be efficiently ventilated within three weeks.

Lord Kelvin.—A weekly newspaper, called *The Syren*, in a short biographical sketch of Lord Kelvin, states that, "by birth, he is an Irishman and a mathematician, for he first saw the light at Belfast, in 1824."

"The Coming Electric Railroad."—Under this title Prof. S. H. Short, of Cleveland, who is now in this country, has contributed to the *Cosmopolitan* a popularly-written article on electric railroad traction in the United States.

Institution of Mechanical Engineers.—The Institution of Mechanical Engineers has now definitely removed from its offices in Victoria-street to its magnificent new quarters at Storey's Gate, St. James's Park, Westminster, S.W.

Royal Society.—At the meeting of the Royal Society yesterday the following Papers were down for reading:—"The Constitution of the Electric Spark," by Prof. A. Schuster, F.R.S., and G. Hemsalech; and "On the Effects of Strain on the Thermo-Electric Qualities of Metals," by Dr. M. Maclean.

The Post Office London-Birmingham Underground Telephone Cable.—We find that in our notice of this cable last week we were in error in stating that the whole of the cable is the British Insulated Wire Co.'s manufacture. We learn that a portion of the cable is being made for the Post Office by the Western Electric Company at their North Woolwich factory.

Owens College.—At the last meeting of the Council the treasurer reported that a donation of £2,000 had been received from Captain Partington towards the cost of building the new physical laboratory. The treasurer also reported that he had received from Dr. E. Hopkinson a sum of £1,884, which had been contributed by the relatives of the late Dr. John Hopkinson for the erection of a wing of the laboratory to be devoted to electro-technical work, and a further sum of £50 from Mr. F. J. Schuster for the same object. The generous gifts already received have enabled the Council to proceed with the building, but a large additional sum is required to enable them to complete and equip the laboratory.

Applications of Ether Waves.—On Monday evening last, under the auspices of the Highbury Literary Association, a large audience of about 1,500 people assembled in Highbury Quadrant Church to hear a discourse by Dr. J. A. Fleming, F.R.S., on "Applications of Ether Waves." The lecture was fully illustrated by experiments. After dealing with the elementary portions of the subject and describing the chief facts which indicate the existence of an optical ether, the lecturer passed on to discuss the experiments of Hertz and the experimental production of electromagnetic waves. Experiments were conducted in the presence of the audience illustrating the process of wireless telegraphy with ether waves. The audience expressed their hearty appreciation of the successful illustrations.

An American Municipal Electric Lighting Plant.—The municipalisation of electric light undertakings is coming to the fore in the United States. The Water Committee of Portland, Ore., have a clause in the new City Charter which provides for the completion of an electric light and water-power scheme by 1905. It is estimated that 160 H.P. could be obtained by utilising the natural flow of the city water from the high reservoirs to the low ones, at the water works. At present a sum of £16,000 is paid annually, for the city lighting, to the Portland General Electric Co.; but the advocates of municipalisation are of opinion that the city lighting should not cost more than £10,000. There are 708 arc lamps of 2,000 c.p. and 637 glow lamps at present in use in connection with the public lighting, and unless current can be contracted for at about 16s. per horse-power per annum it is intended to erect a municipal electrical system.

The Institution of Electrical Engineers.—At the last meeting of the Institution of Electrical Engineers Dr. Silvanus P. Thompson, who presided, announced that the Council, acting upon the powers conferred upon it by the new Articles of Association, had elected an honorary member. Honorary members, he said, could only be elected one in each year. Under the old Articles of Association the choice of the Council was restricted, inasmuch as they could only elect as honorary members persons of distinction who were not in actual practice as electrical engineers or electricians, all others being excluded. For two or three years past it had been the wish of the Council to do honour to the greatest living electrical engineer and electrician, viz., Lord Kelvin, by elect-

Digitized by Google

ing him as honorary member, but they had been debarred from doing so by the fact that the old Article 18 forbade the election of one in actual practice. When the new articles were being drawn up in the summer and autumn of last year this article had been revised in order that they might have in the future a power from which they had been excluded in the past. The new article, therefore, contained no such restriction, and, coming into force on January 1st this year, the Council had naturally taken the earliest opportunity of nominating Lord Kelvin for election as honorary member. It had communicated to Lord Kelvin its desire to elect him, and he had been good enough to say that he was flattered by the wish of the Council to put him into that position—the first under the new rules, and he had intimated that he acceded to the wish of the Council, whereupon the Council had that evening elected him an honorary member of that Institution.

The Fire Prevention Committee's Testing Station.—The new testing station of the British Fire Prevention Committee was opened on Tuesday last. The station consists of two private houses standing on their own ground, on one bank of the Regent's Canal, near Regent's Park. The principal building will be used for committee rooms and laboratories, while in the gardens have been erected three large brick testing chambers or "huts" for furnace tests of fire-resisting materials in large quantities. Near these huts there has been erected a water-gas generating plant, consisting of a small vertical boiler and gas producer, the gas from which is conveyed direct through a large main and sluice valves to the huts, on the flame chamber floors of which it is burned at a number of nozzles. Immediately above the flame chamber is the testing chamber, communication with which, in each case, can be made electrically, from two Roberts-Austen electrical pyrometers, which have been erected in one of the laboratories. These pyrometers make photographic records of the temperature, and also indicate the momentary temperature by a spot of light on a direct reading scale. The primary objects of the Committee are: Firstly, to direct attention to the urgent need for increased protection of life and property from fire by the adoption of preventive measures; secondly, to use its influence in every direction towards minimising the possibilities and dangers of fire; and thirdly, to undertake independent investigations and tests of materials, methods and appliances for fire resisting purposes. Thus it will be possible to obtain reliable records as to the merits of various materials. The tests will be of an independent character, carried out on scientific lines with reference to practical purposes. The reports of tests will state simply the bare facts of occurrences, with tables, diagrams and illustrations, and, it is stated, will on no account include expressions of opinion or any expression that might be read as comparison or criticism. The tests will be under the direction of an executive committee, presided over by Mr. E. O. Sachs, and including a number of names well known to the electrical engineering profession.

The Measurement of Elasticity.—At a meeting of the Institution of Junior Engineers, at the Westminster Palace Hotel, on Friday, January 27th, a lecture was given by Prof. Ewing on "Measurements of Elasticity." After a general account of what is meant by elasticity and elastic strain, the lecturer proceeded to define the various constants by which the elasticity of a material could be expressed. The ones usually measured were Young's modulus of elasticity, or the stretch modulus, and the modulus of rigidity, or the shear modulus. From these two the other constants could be inferred. In measuring Young's modulus the whole amount of elastic stretching in such a substance as wrought iron did not much exceed one one-thousandth of the original length. The determination of the modulus with any accuracy, therefore, required measurements of great refinement, except in the case of wire where long lengths could be dealt with. For experiments with long wires a simple scale and vernier, reading, say to hundredths of an inch, would suffice, but for short specimens such as were used in the testing machine, where the measurements were made on a length of eight inches or so, extensometers were required capable of reading at least to ten-thousandths and much preferably to fifty-thousandths of an inch. The lecturer showed several forms of an extensometer of his own invention which had been found convenient and accurate. This instrument is entirely self-contained and is attached to the piece under test by two set-screws at the ends of the length on which the observation of extension is to be made. In its usual form for tension tests it reads to one fifty-thousandth of an inch, but in a special form designed for measuring the elastic compression of short blocks, the readings are taken to $\frac{1}{250000}$ in. The lecturer next described the very imperfectly elastic condition into which iron or steel is thrown by straining beyond the ordinary limit of elasticity. Immediately after being overstrained and when the load is removed, the piece on being reloaded does not follow Hooke's Law at all, and cannot be said to have any elastic limit. But as time passes the elasticity comes back, and after an interval of a few days in the case of wrought iron, or of many weeks in the case of steel, it is found that the material has practically perfect elasticity up to a limit which may be much higher than the initial elastic limit.

Cosmopolitan Lamp Data.—Messrs. R. S. Hale and J. S. Codman, in an article in the *Electrical World* for January 7th, have compiled a number of statistics of the lamp data of American and other important cities. From a table in this article we gather that the distinction of having the greatest number of glow-lamps per thousand inhabitants may be claimed by Boston, the number of lamps being 1,232. Next in order is New York, with 859 lamps per thousand inhabitants. Below we give the table referred to:—

City.	Population.	Lamps, arcs and motors in 16 c.p. equivalent.			Lamps per 1,000 inhabitants.	
		Central stations.	Isolated plants.	Total.	Central stations.	Total.
Boston	500,000	418,000	198,000	616,000	836	1,232
New York	2,000,000	978,000	740,000	1,718,000	489	859
Chicago	1,750,000	513,000	765,000	1,278,000	294	730

Wave Motion near a Theoretical Hertzian Oscillator.—In a Royal Society Paper, read January 19th, Prof. Karl Pearson and Miss Lee investigate the variations in the field round a *theoretical* Hertzian oscillator. The italics emphasise that a Maxwellian "double point" of initial maximum moment $\pm El$ is understood, but as the actual oscillator has been shown by Bjerknes and others to give a damped wave train, the maximum moment is taken to run down with the time, and to oscillate between the limits $\pm Ele^{-pt}$. Hertz's own theory, adopted in most text-books, is considered insufficient because the actual oscillator has sensible extension and its wave train is not steady. The present Paper attempts to remove the latter objection only, and confines itself to a theoretical investigation of the damping of the wave train. A series of diagrams, to replace the well-known Hertzian diagrams, have been produced by Miss Lee, representing the

Digitized by Google

field for seven complete oscillations, and showing how the field for some 12 metres round the oscillator chosen gradually falls to $\frac{1}{10}$th of its maximum initial strength. Dealing next with the type of waves propagated, their velocities and their phases, the authors conclude that three waves of electromagnetic force, instead of two, may be considered as sent out, viz., a wave of purely transverse electric force, a wave of electric force parallel to the axis, and a wave of magnetic force. The following summarises their remaining conclusions. The velocities of these waves undergo remarkable changes in the neighbourhood of the oscillator, these changes extending to distances greater than those within which a great proportion of Hertz's interference experiments were made. The point of zero phase for both transverse and axial electric waves does not coincide with the centre of the oscillator, so that these waves appear to start from spheres of small but finite radius round the oscillator. A fourth wave dealt with by Hertz, namely, the wave of magnetic induction, does not, as he supposes, start with zero phase from the origin, but with a finite phase. The wave in the equatorial plane, largely relied upon by Hertz for his interference experiments "of the first kind," is a compound of the waves of transverse and axial electric force, and has a much more complex series of velocity changes than Hertz appears to have realised. Hertz's experiments should be made at distances greater than 6 to 7 ($\lambda/2\pi$) from the centre of the oscillator. In Hertz's case this amounts to about 10 metres—a distance at which Hertz rather terminated than started his interference experiments. Only at such a distance are the phase curves sensibly linear.

The Telephone Service.—A series of three articles, published in *The Times* of January 20, 23 and 24, gives from the pen of "a correspondent" an admirable statement of the telephone question from the point of view of a supporter of the National Telephone Co. Although taking sides with the Company, and severely criticising the action and inaction of the Government since the inception of telephony in 1877-8, the historical facts are accurate and fairly complete. Starting with the formation and amalgamation of the Bell and Edison companies, and the "initial blunder" of the Post Office in not acquiring the telephone patents in those early days, when it had the opportunity, the first article goes on to mention the famous law suit in which the telephone was declared a telegraph in 1880, and the policy pursued by the Government in granting licences and imposing restrictions, until the amalgamation of the United Telephone Co. with its affiliated companies. It is stated that the difference between the aggregate valuations of the amalgamated companies and the actual construction cost was £1,280,768 in £4,565,027, and this figure has remained a constant quantity, while the capital invested at June 30 last stood at £6,264,260, and the Company had accumulated a reserve fund of £600,000. The second article commences with the debate in the House of Commons in 1892 on the motion of Dr. Cameron in favour of the nationalisation of the telephone service, and the declaration of the Government of its intention to purchase the trunk lines. This is followed by copious extracts from the famous Treasury Minute, and an account is then given of the various developments up to the publication of Sheriff Jameson's report on the Glasgow inquiry. In this article, it is stated, with regard to the inquiry by the Select Committee of the House of Commons in 1895, that :—

> It is a matter of common knowledge, however, that the chairman submitted a report to the Committee condemning the granting of any municipal licences; but as Parliament was then on the eve of a dissolution, and the Committee were not unanimous, the report was withdrawn.

It will be remembered that this Committee merely published the full minutes of the evidence taken, without presenting any report to Parliament. The last of the three articles deals with the "latest departure in Government policy," upon which it comments shrewdly. Of the statement made by Mr. Hanbury during the telephone debate on April 1, 1898, to the effect that the Company's plant and system could be replaced for a little over two millions, it is said :—

> Upon what evidence Mr. Hanbury made this statement is not known, but one more incorrect or calculated in the mouth of a responsible Minister to injure the Company is impossible to imagine. The best answer that can be given to Mr. Hanbury is that the Company has expended, in cash on its plant, machinery and system, upwards of £5,000,000, of which amount the sum of nearly £2,500,000 has been spent since 1892, on the faith of the arrangements concluded with the Government, and with respect to which Mr. Preece stated before the Committee of 1895 that the Company was employing the best materials, was doing its work in a way of which he approved, and that if the Post Office took over the system in 1911 it would (if the Company continued to do as they were doing) have a first-rate system with first-class materials and telephones.

The formation of the 1898 Select Committee, and its report, are thoroughly criticised and the article is summed up by a list of the six mistakes of the Post Office with regard to the telephone question, viz., its refusal to acquire the patents originally, its policy of impeding and harassing the companies during their development, the favouring of unlimited competition and failure of this policy, the acquisition of a portion only of the companies' undertakings, the refusal of adequate powers for running lines, and finally its contemplation of a reversion to the old policy of obstruction "coupled with an unfair competition." It should be mentioned that, in the course of the last article, it is stated that the Postmaster-General has given the Company notice that he does not intend to grant it any more wayleaves to carry its wires along railway lines, in any place where the Postmaster-General is, or is likely to be, in competition with the Company. The granting of these wayleaves was, it is said, held out in the Treasury Minute of 1892, as one of the principal inducements to the Company to fall in with the policy of the Government and part with the trunk lines.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

MONDAY, February 6th.

SOCIETY OF ENGINEERS.

7:30 p.m. Ordinary Meeting at the Royal United Service Institution, Whitehall. The President for the past year, Mr. W. W. Beaumont, will present the premiums for Papers read during the year, after which Mr. John Corry Fell, the President elect, will deliver his Inaugural Address.

TUESDAY, February 7th.

RÖNTGEN SOCIETY.

8 p.m. General meeting at 11, Chandos-street, Cavendish-square, W., when Mr. Wilson Noble will read a Paper on "A Modified Form of Toepler Mercury Pump." The President will then introduce a discussion on "The Röntgen Ray Photography of Soft Tissues."

WEDNESDAY, February 8th.

SOCIETY OF ARTS.

8 p.m. Ordinary meeting. Paper to be read: "Nernst's Electric Lamp." By James Swinburne.

THURSDAY, February 9th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting, when the discussion on the following Papers will be continued:—(1) "Rules for the Regulation of the Wiring of Premises for Connection to Public Supply Mains," by J. Pigg; (2) "The Regulation of Wiring Rules," by C. H. Wordingham; (3) "The Institution Wiring Rules," by R. E. Crompton. Time permitting the following Paper will be read: "Electric Traction by Surface Contacts," by Miles Walker.

SOCIETY OF ARTS.

8 p.m. Adjourned Discussion on Mr. Dixon H. Davies' Paper "The Cost of Municipal Enterprise."

FRIDAY, February 10th.

PHYSICAL SOCIETY.

5 p.m. Annual General Meeting in the Rooms of the Chemical Society, Burlington House, W. Address by the President. At the Ordinary Meeting which follows, a Paper on "An Ampere-Meter and a Volt-Meter with a Long Scale," by Benjamin Davies, will probably be read by Dr. Oliver Lodge.

INSTITUTION OF MECHANICAL ENGINEERS.

7:30 p.m. Annual General Meeting at the New Institution Building, Storey's Gate, St. James's Park. Among the Papers down for reading is one by H. G. V. Oldham, on "Evaporative Condensers."

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Students' Meeting. Paper to be read, "The Electrical Driving of Engineering Workshops," by W. Middleton.

ROYAL INSTITUTION.

9 p.m. Evening Discourse, "The Motion of a Perfect Liquid," by Prof. H. S. Hele-Shaw.

SATURDAY, February 11th.

INSTITUTION OF ELECTRICAL ENGINEERS.

2:30 p.m. Students' visit to the Shoreditch Central Station, Coronet-street, Shoreditch. Party limited to 20.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture on "The Mechanical Properties of Bodies," by the Right Hon. Lord Rayleigh F.R.S.

Digitized by Google

NOTES ON THE TURIN INTERNATIONAL EXHIBITION.

(BY OUR OWN CORRESPONDENT.)

(*Concluded from page 41.*)

One of the novelties in Messrs. Ganz's exhibit of dynamos and motors was a distributing system on the Ferraris-Arnó principle.* This method was suggested by Prof. Ferraris a few months before his death, and it has been successfully worked out by his distinguished assistant Prof. Arnó. Suppose an alternating current motor with four coils, A, A', B, B', set at right angles and connected as shown in Fig. 8. If two alternating currents, differing 90deg. in phase, are sent through them, as shown in the figure, a rotatory field is

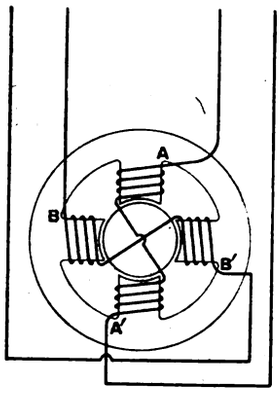

FIG. 8.

produced, and if the armature is given a definite polarity it will rotate at the same speed as the field. Now if the circuit B B' be interrupted the motor will work as an alternating-current synchronous motor, and it will at the same time generate an E.M.F. at the terminal of the circuit B B', differing 90deg. in phase from the primary current in A A'. Once started, the motor, therefore, acts as a transformer, the E.M.F. in the secondary B B' depending on the number of turns of the coils. With the aid of a stationary transformer (Fig. 9) this induced E.M.F. may be made two-phase, although the current in the main circuit is only single-phase. It is also possible to have three wires in the secondary circuit, as in Fig. 10, instead of two. This latter method of

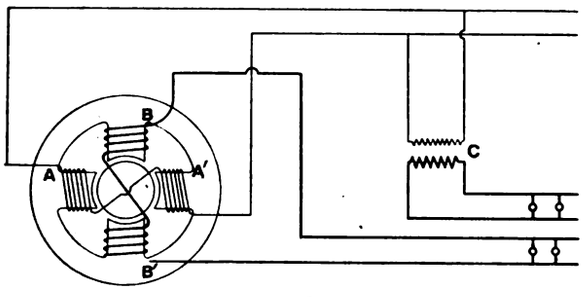

FIG. 9.

connection is used especially for starting motors, with the aid of a third wire from one of the transformers. Messrs. Ganz had nine motors in various parts of the exhibition started on this principle.

A 70 kilowatt three-phase dynamo, exhibited by the same firm, has some points of interest. The coils are stationary, and there are 10 revolving pole-pieces, five on each side of the armature. These are not placed opposite one another, but shifted at an angle of 24deg. By increasing this angle to 36deg. the machine is made two-phase, and by placing the poles opposite to one another it generates single-phase alternating currents. Amongst other machinery of Messrs. Ganz's may be mentioned a 100 kilowatt three-phase transformer, several continuous and alternating-current motors (*see* Fig. 11), and an apparatus for the automatic switching in and out of transformers.* The latter is said to work well, but it appears to me that there are too many mercury contacts.

Mechanical Applications of Electricity.—These were very numerous. The Officine of Savigliano exhibited a 5-ton electric crane, several electrically-driven drills, both stationary and portable, and an electric hammer. Messrs. Larini Nathan and Co. showed a 15-ton crane, operated by three Belloni and Gadda motors, and the latter firm, as well as Messrs. Brioschi and Finzi, demonstrated the suitability of electric motors for driving light cotton and wool machinery. There were also several electrically-driven lathes exhibited by various Italian firms, and Messrs. Worthington's pumps were also actuated by electricity. The most important mechanical application of electricity, however, was an enormous turret with two powerful guns, for the Italian Navy, which was moved entirely by electrical power. On the other hand, the exhibits under this heading which attracted most attention were, perhaps, the numerous electrical fans.

Storage Batteries.—A large number of firms, chiefly Italian, had batteries of storage cells on view, these being, however, with but two exceptions, of foreign make. Thus the new Tudor pattern, and the Hagen, Elieson, and Blot batteries were represented. In a cell exhibited by the Societá Cruto of Torino, made under Col. Pescetto's patent, a paste is used, consisting of a mixture of lead oxides and a substance obtained by a reaction of sulphuric acid upon sugar. The latter is said to increase the conductivity. In the Garassino cell, made by Messrs. Vandel, of Avigliana, the active material is spongy lead, obtained by the electrolysis of lead oxide, and mechanically compressed.

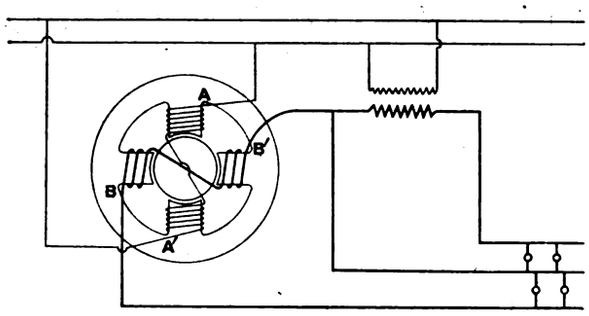

FIG. 10.

Instruments.—Messrs. Siemens and Halske had a large number of measuring instruments in their exhibit. Among these were, on the one hand, voltmeters and ammeters of the moving coil pattern, and, on the other hand, wattmeters which were everything except dead-beat. The Siemens and Halske integrating meter is based on a similar principle to Lord Kelvin's. A lever actuated by clockwork swings continuously to and fro, and, when current is passing through the ammeter portion, this lever engages with the train of the registering wheels, the angle through which the first wheel of the train is rotated depending on the current. The Compagnie pour la Fabrication des Compteurs Electriques of Paris had meters of the Cantono-O'Keenan, Thomson and Duncan patterns, and Déri and Hummel meters were exhibited by Messrs. Ganz and Co. and the Allgemeine Electricitäts Gesellschaft respectively. Other exhibitors of voltmeters, ammeters and laboratory instruments were Messrs. Hartmann and Braun, the Weston Electrical Co., the Tecnomasio of Milan and Mr. Olivetti, of Ivrea, the instruments shown by the last-named having some points of novelty. Mr. Marconi exhibited his celebrated instruments in the Marine section, and performed successful experiments, and Prof. Rosa demonstrated how Herzian waves could be applied to synchronise clocks.

Wire and Cable.—There were only two exhibitors of insulated wire and cable, viz., Messrs. Pirelli and Co., of Milan, and Messrs. Tedeschi, of Torino. The former showed an interesting collection of all the materials and apparatus used in connection with the manufacture and laying of rubber

* See also *The Electrician*, Vol. XL, p. 254.—[ED. *E.*].

Digitized by Google

cables, from a specimen of the *Ficus Elastica* to a complete outfit for the laying of submarine cables. Among their exhibits was an underground cable, submitted to a pressure of 20,000 volts for the benefit of the visitors.

Literature.—Messrs. Rosenberg and Selier, of Torino, provided a collection of English, American, German, French, Italian, Spanish and Russian books and journals relating to electricity. These were placed at the disposal of the public, and were greatly appreciated.

Historical.—The electrical industry in Italy is only at its commencement, but there is no doubt that some of the most striking discoveries in the domain of electricity during the present century are due to Italian workers. The bad political and economic conditions under which Italy has suffered, and is still suffering, and a certain contempt of the Latin races for practical industries, have caused this country to be among the last nations to enjoy the benefits of these inventions. But yet such men as Ferraris and Pacinotti are highly esteemed by their fellow countrymen, especially by those who are among the ranks of the workers. At the Turin Exhibition the early apparatus made by Volta, Galvani, Ferraris and Pacinotti were exhibited. The famous controversy between Galvani and Volta was illustrated by the original apparatus. The early electric piles were to be seen, the cells in separate glasses devised later, and Volta's electrometers, condensers, electrophorus, &c. All the rough apparatus made by Ferraris in 1885 for demonstrating the principles of the rotatory field were also shown, and last, but not least, Pacinotti's first continuous-current dynamo of 1864, with the toothed armature which has been revived in modern machines. Pacinotti did not only invent the ring armature; there are disc and drum armatures to be seen ante-dating those of Siemens and Edison. It may not be generally known that Prof. Pacinotti is still living, and is by no means an old man. He is Professor of Physics at the Agricultural School at Pisa, and has not of late been devoting attention to electrical subjects.

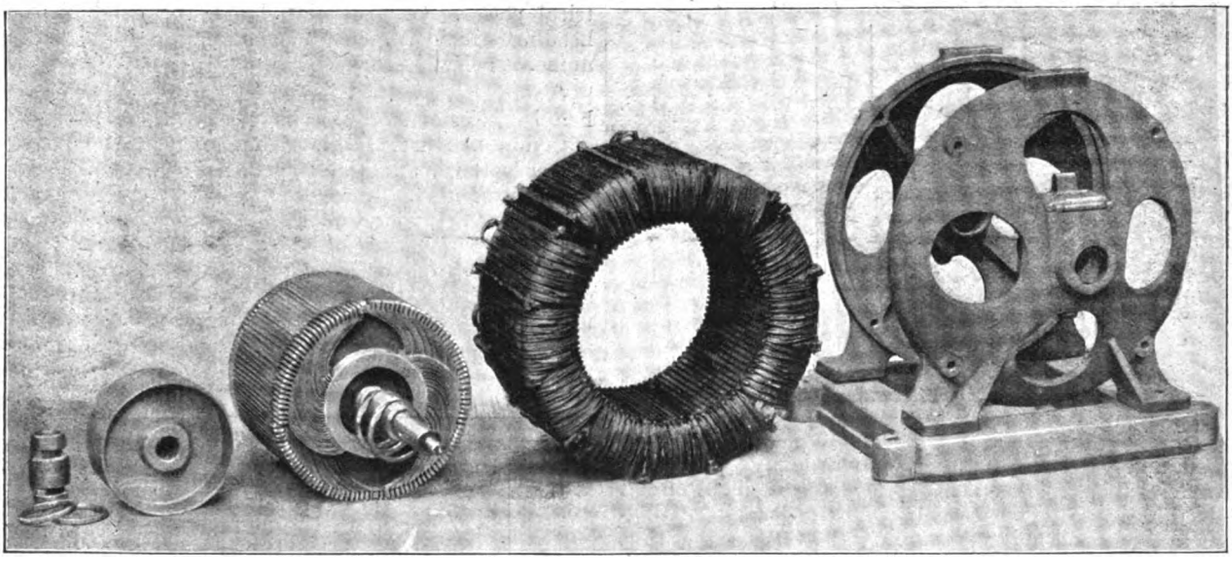

FIG. 11.—GANZ THREE-PHASE MOTOR.

GLASGOW CORPORATION NEW ELECTRIC SUPPLY WORKS.—A STUDY IN EMERGENCY WORK.

In view of the recent starting of the new electric supply works in Glasgow, a short history of the electrical enterprise of the "second city" might not be without interest to our readers, by way of preface to some account of the new works.

The introduction of electric lighting into Glasgow was due to private enterprise, and dates from as far back as 1885, in which year the pioneers of the firm which is now known as Messrs. Mavor and Coulson (Limited) laid down a lighting plant consisting of some 200 H.P. About 1890, owing to the success of this undertaking, the same firm were induced to form a company and to secure premises in John-street, where they laid down a Ferranti alternating current plant, with which they supplied an extended district in the neighbourhood by means of overhead cables, the maximum output being some 80 amperes, at 2,500 volts. By this time the Glasgow Corporation, seeing that the gas works were already municipal property, and that it would not be well to have a competitive lighting system, decided to buy up the private enterprise, and secured the Millar-street and the John-street stations as a going concern for £15,000. The Corporation immediately set to work to give a more extended supply. The site in Waterloo-street was secured, and a low tension three-wire system was laid down for private lighting, with a series system for the arc lighting. The supply was started in February, 1893, from the Waterloo-street station, and the plant then consisted of seven Willans units of a total of 1,400 to 1,500 H.P. for the incandescent lighting, with four Brush arc lighter driven from two Easton, Anderson and Goolden engines for the street lamps, 77 Brush lamps being erected at first, although the plant was arranged for 112. The mains laid down at first for the private lighting were entirely on the Kennedy bare copper system. The following year it was necessary to increase the station and two plants of 225 kilowatts each were laid down. This necessitated the removal of the arc lighting plant to the disused station at John-street, where the Brush dynamos were run from the original engines. In the following year it was again found necessary to increase the plant, and two more units were laid down. Again, in 1896, another two similar plants had to be added, which last two completely filled up the available space at Waterloo street. The increase of boiler plant, we might add, followed on the same lines as the engines, the original equipment consisting of five marine type boilers of 300 H.P. each, another similar one being added in 1894, two Babcock-Wilcox, of 700 H.P., in 1895, and another of the same size in 1896, to complete the station.

With this station full up, and no further scheme ready matured, the position of the Glasgow electricity supply undertaking began to enter upon the serious position in which it now finds itself, but which, from all appearances, it will very soon triumphantly emerge. In order to cope with the load at the peak there were put down, in the autumn of 1897, two large Tudor batteries, each of 2,000 ampere hours capacity, and capable of being discharged in an hour if necessary, one being placed about a mile west of the central station and the other about a mile to the east.

In the autumn of 1897 Mr. Arnot, the Corporation electrical engineer, resigned, and the Council advertised for a successor who should not only act as a chief engineer, but should also

Digitized by Google

be capable of carrying out all the duties of a consulting engineer to the Corporation. The choice fell upon Mr. W. A. Chamen, who was at that time with Messrs. Crompton and Co. as their chief engineer. Mr. Chamen took up his duties early in 1898, and found the state of affairs such that any extra strain at the station would cause more or less serious interference with the lighting, as during the peak it was necessary to run the whole of the station plant, and to discharge the batteries at their full output, recharging them again as the machines became available on the falling off of the load at night. It was not long before Mr. Chamen had his scheme fully matured and laid before the Council, who authorised

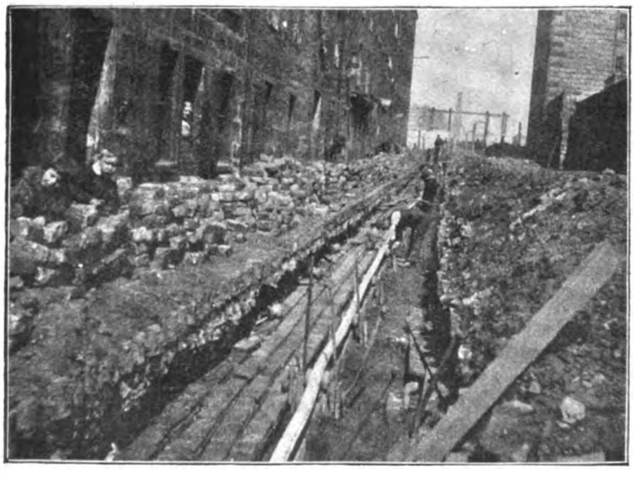
him to forthwith push on with it. This scheme embodied a 500-volt supply with 250 volts on the consumer's terminals.

Suitable sites for new generating plant were secured, one on the north side of the Clyde at Port Dundas, adjacent to the Forth and Clyde Canal, with convenient facilities for water and fuel; the other on the south side of the river, with suitable railway sidings. The site on the north side was the first to be considered, as the station on it was to relieve the overload on the existing Waterloo-street station. Mr. Chamen found that it would be impossible to get plant of his own selection erected to meet the following winter's load, so he advertised for tenders for any plant of whatever sized units offerers

Trench with Pulleys in Position and Length of Cable about to be Laid

might find most convenient, either new or second-hand, with the only stipulation that they were to be on the ground by the following August. As a result of this, the plant subsequently described in this article was offered and accepted by the Corporation. Unfortunately, however, owing to disputes in the building trades and other causes the foundations were not ready to receive the plant by the time specified, although the bulk of the plant was fairly well up to time as far as the delivery was concerned, and as a consequence the first engine was not got under steam till quite the end of the year.



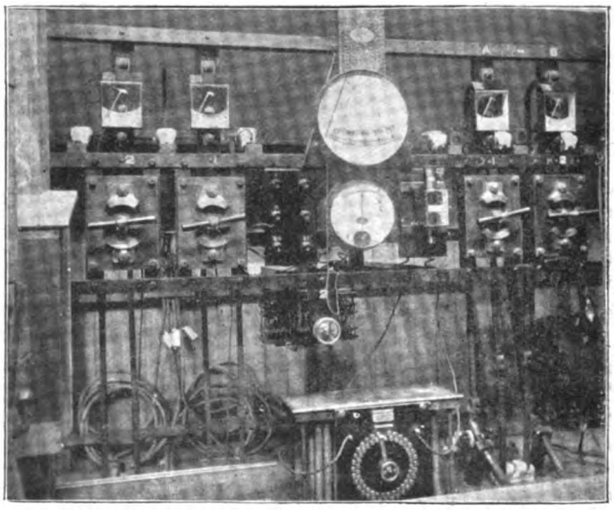
Trench running South from New Power Station; Four Feeders in Position, and the Fifth being Laid.

Happily, Mr. Chamen had foreseen the possibility of some hitch occurring in the delivery of the plant, and soon after his arrival at Glasgow he refused to make any more coneections to the mains, except under a signed agreement that the consumer should be cut off if at any time the exigencies of the demand demanded it, owing to too great a strain on the station. During the early part of the present winter, by dint of running the plant at about 25 per cent. overload during the two hours of the peak, things were kept going in a very satisfactory manner, and the voltage rarely fell much below the normal. Early in December last the demand increased to such an extent that it was found necessary to disconnect 160 of the recent consumers who had been connected under the agreement above referred to, although in a number of cases these consumers were reconnected during the daytime, and only disconnected during the peak.

The new station is a handsome pile of buildings of red pressed bricks, relieved with red sandstone facings, erected on a site adjacent to the Port Dundas Canal. The canal will afford a cheap and easy method of delivery of fuel, removal of ashes, &c., although at the same time, if it is found necessary, by the erection of a light swing bridge across the canal, the

Cable about to be Drawn-in from a Drum.

railway siding which runs along the opposite bank can easily be carried into the coal store. The station buildings consist of a central tower, in which is situated a suite of offices for the works manager, and also fully-equipped test rooms, &c., required for the proper working of the station. On either side of this central tower is a battery room, 77ft. long by 26ft. wide. Behind is the main machinery hall, 553ft. long by 59ft. wide, and 30ft. high to the travelling crane rails. This is lined throughout with white glazed bricks. Parallel to this



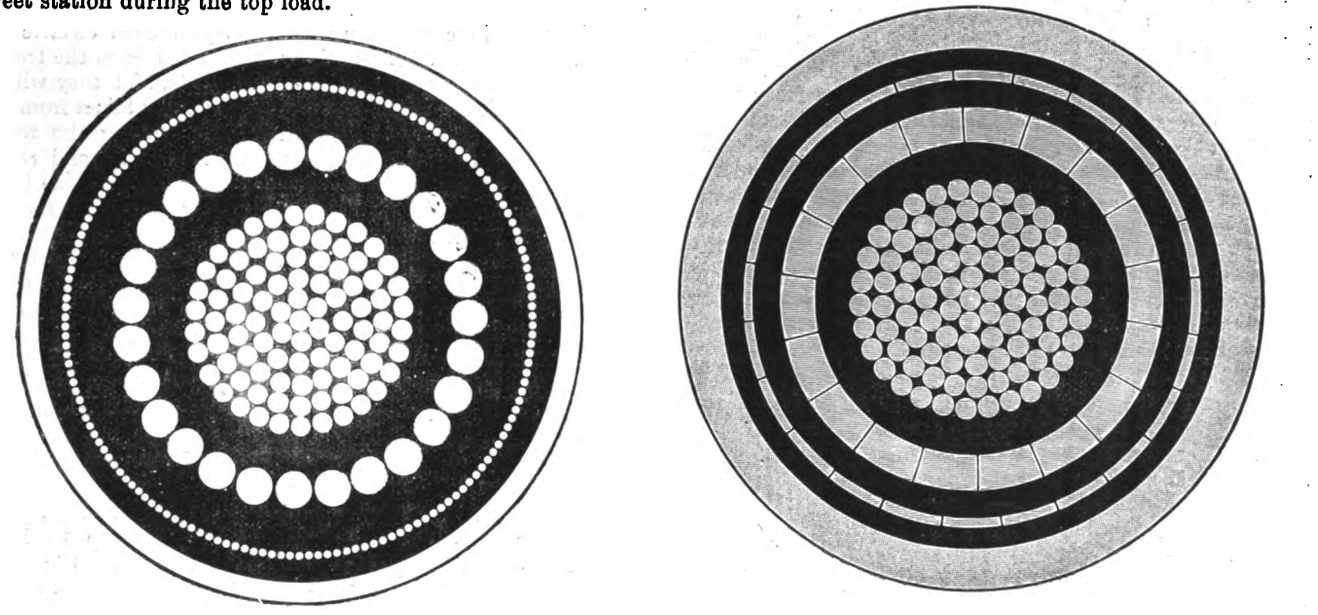
Temporary Switchboard.

and immediately behind is the boiler house, 559ft. long by 81ft. wide, also lined with white enamelled bricks. The central chimney is 200ft. high by 11ft. diameter, and the two outer ones each 250ft. high by 13ft. diameter. To the rear of the boiler house is a coal store capable of accommodating upwards of 2,000 tons of fuel as a reserve stock, above which are coal tanks to contain the daily supplies as required. The canal extends along the whole length of this store, and the fuel can be discharged by an electrically-driven Temporley trans-

Digitized by Google

porter, direct from the barges into either the store or the supply tanks. The comfort of the employees has been carefully considered in arranging the station, and numerous rooms are provided for the staff in each department, all being fitted with bath rooms and lavatories. The station buildings are designed to ultimately accommodate upwards of 30,000 I.H.P. of plant, but the present contracts now in progress are only for the central portion, consisting of the tower, the battery rooms, and the central third of the machinery hall, boiler room and fuel stores, &c. This portion will allow of some 10,000 I.H.P. of plant being erected.

As the permanent buildings were not ready to receive the plant in time for this winter's load, and as it was imperative that part of it should be running to assist the heavily overloaded Waterloo-street station, a temporary wooden shed some 80ft. long by 35ft. wide was erected over the permanent foundations to house the first instalment of some 2,200 I.H.P. of plant. The permanent boilers were put in and a galvanised iron shed was put up over them, and a temporary iron chimney 5ft. diameter by 100ft. high was erected on one side of the central chimney shaft. By this means, and by connecting up a few feeders to the central area of supply with a temporary switchboard, a considerable amount of assistance has been rendered daily for the past few weeks to the Waterloo-street station during the top load.



CALLENDER'S CABLE. SECTIONS OF THE TRIPLE CONCENTRIC MAINS. B. I.W. CABLE.

Weight = 45 tons per mile; Copper Section = 1 sq. in.; Scale, full size.

The plant installed in this temporary shed is erected in its final position and on its permanent foundations, and as soon as the main roof is on the shed will be removed. The plant comprises a vertical compound engine, made by the Ball and Wood Co., of New York, having cylinders 20½in. and 44½in. diameter and 24in. stroke, with a speed of 150 revolutions per minute. The cylinders are fitted with Corliss valves. To each end of the shaft of this engine is coupled an eight-pole dynamo, made by the Walker Co. Each dynamo has an output of 300 kilowatts at 250 to 300 volts, but is capable of taking an overload of 50 per cent. The carbon brushes do not require adjustment between no load and 25 per cent. overload. The field magnets are compound wound, so that the machines can be used as tramway generators when so required. A separate surface condenser having the air and circulating pumps driven by electric motors has been supplied by Messrs. W. H. Allen and Co., of Bedford.

The next set consists of a vertical triple-expansion condensing marine engine with condenser, the pumps being driven off the I.P. cylinder crosshead. The diameters of the cylinders are 17in., 25½in., and 38in. respectively, with a 30in. stroke, running at a speed of 120 revolutions per minute. The governor is of the throttle type, and is fitted with suitable adjustment for varying the speed while running. This engine is coupled direct to a shunt-wound twelve-pole Schukert dynamo, with a capacity of 550 kilowatts at 500 to 600 volts. The set was supplied under contract with Messrs. Mavor and Coulson, of Glasgow.

The remaining plant consists of two engines by the Mirilees, Watson and Yaryan Co., of Glasgow, of their new enclosed type. It comprises one 400 H.P. triple-expansion engine having cylinders 14in., 22in., and two 24in. diameter respectively, with a stroke 12in. and a speed of 380 revolutions per minute. There are four cranks at right angles. The other set consists of a 200 H.P. compound engine, with cylinders H.P. 14in. and 21in. diameter, with a 12in. stroke, running at 380 revolutions per minute, the two cranks being placed opposite each other. These engines are directly coupled to two shunt-wound two-pole Crompton dynamos, having outputs of 255 and 125 kilowatts respectively, at 500 to 600 volts. The contract for these plants was with the engine builders. Both engines exhaust to one condensing plant of the same type as the American engine, supplied by Messrs. W. H. Allen and Co. In all cases the air pumps are of Edwards's design, and the gearing is of Hollicks's balance friction type.

Two sets of balancing motor-dynamos have been supplied by the India Rubber, Gutta Percha and Telegraph Works Co. (Limited). Each set can be coupled to the three-wire system, and each side of each set is capable of dealing with an output of 150 amperes at 230 to 300 volts at a speed of 650 revolutions per minute. The field-magnets are compound-wound, and all the necessary starting and regulating resistances have been provided by the makers.

Two sets of boosters for charging the batteries have been provided by Messrs. Mavor and Coulson, of Glasgow. The motors are shunt wound, and take current from the 'bus bars at 500 to 600 volts, and the boosters have an output of 225 amperes at 20 to 160 volts. They are separately excited at 250 volts, and run at 850 revolutions per minute. The makers have supplied all the necessary starting and regulating resistances.

A storage battery has been supplied by the Tudor Accumulator Co., and consists of 335 cells, arranged in two sets on the 500 volt three-wire system. There are 25 pairs of regulating cells on each half battery. The capacity of the battery is 1,100 ampere-hours, at a discharge of 150 amperes, and it can stand a maximum discharge rate of 250 amperes.

The present switchboard is only of a temporary character, constructed by the station staff to meet the immediate requirements, but tenders have been accepted for the permanent gear, which will be erected as soon as the permanent buildings are completed, and the wooden shed removed.

The steam and feed pipes consist of welded wrought

Digitized by Google

steel with flanges welded on solid. The valves are of the Templer and Ranoe type. The feed pumps are only a temporary arrangement at present, and consist of a Wier's steam pump and a three-throw electrically-driven pump made by Messrs. Hayward-Tyler and Co., fitted with Hollicks's patent gear. The motor is run off either a 250 or 500-volt circuit, a further range of speed being obtainable by sliding the magnets along over a dummy armature, thus reducing the lines of force passing through the windings.

At present only two boilers have been erected, these being of the Babcock and Wilcox type. Each has an evaporative duty of 15,000lb. of water per hour at 200lb. pressure. A superheater has also been fitted in the combustion chambers. The furnace firing is done by chain stokers driven by electric motors.
